This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world’s books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that’s often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book’s long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ **Make non-commercial use of the files** We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ **Refrain from automated querying** Do not send automated queries of any sort to Google’s system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ **Maintain attribution** The Google “watermark” you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ **Keep it legal** Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can’t offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book’s appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google’s mission is to organize the world’s information and to make it universally accessible and useful. Google Book Search helps readers discover the world’s books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at [http://books.google.com/](http://books.google.com/)
THE
SECOND SUPPLEMENT
TO THE
PENNY CYCLOPAEDIA
OF
THE SOCIETY
FOR THE
DIFFUSION OF USEFUL KNOWLEDGE.

COMPLETE IN ONE VOLUME.

LONDON:
PUBLISHED BY KNIGHT & CO., 90, FLEET STREET.

MDCCCLVIII.
LONDON:
BRADBURY AND EVANS, PRINTERS, WHITEFRIARS.
NOTICE.

THE FIRST SUPPLEMENT of the 'Penny Cyclopædia,' in Two Volumes, was published in 1846. THE SECOND SUPPLEMENT, now completed in One Volume, follows the same plan as that of the original Work, comprising under one Alphabetical Arrangement, the accumulated information of the twelve years which have elapsed since the publication of the First Supplement. A limited number only of this Volume has been printed; and it will not be kept on sale after that number has been disposed of.

CHARLES KNIGHT.

May 28, 1858.
SECOND SUPPLEMENT
OF
THE PENNY CYCLOPAEDIA
OF
THE SOCIETY FOR THE DIFFUSION OF
USEFUL KNOWLEDGE.

[The abbreviation S. 1, in the references and elsewhere, refers to the First Supplement; S. 2, to the present Second Supplement. The references without either of these additions are to the ‘Penny Cyclopaedia’ as distinct from the two Supplements.]

A A C

AACHEN. [AIN-LE-CHAPELLE.]

ABACO. [BAHAMAS.]

ABATEMENT. Pleas in abatement for misnomer have been abolished (3 & 4 Will. IV. c. 43), and an objection thus taken to the non-jointer or misjoinder of parties is no longer of any avail in a civil action, the courts having now ample powers of amendment. (Common Law Procedure Act, 1852.) A similar observation applies to pleas in abatement to an indictment or information. (14 & 15 Vict. c. 150.)

ABBEY-HOLME. [CUMBRIA.]

ABBEYLEIX. [QUEEN’S COUNTY.]

ABROTS BROMLEY. [STAFFORDSHIRE.]

ABEAKHENTAH, a large walled town, on the west bank of the river Agonee, which separates it from the kingdom of Dahomey, about 60 miles inland from Lagos, in the Right of Biafra, and about 160 miles from Abomey, the capital of Dahomey. It is in the petty kingdom of Egba, which is situated to Yorribah, but the town itself, which has sprung up within the last forty years, is independent, and is governed by a chief who is not a king. The inhabitants amount to upwards of 50,000, and are composed of the natives of Egba, a vast number of liberated blacks, many of them from Sierra Leone, and several missionaries, who report that their labours have been highly successful. The King of Dahomey is more than once attacked the town in vain. In 1848 one of his Amazonian regiments was almost entirely destroyed by the Abeakhenkafa in one of these attempts. In June, 1850, when Captain F. E. Forbes and Mr. Becroft were at Abomey, Mr. Becroft was told by the King himself to warn the missionaries to withdraw, as he was going to make war upon the town, when it was explained to him that the town was in alliance with Great Britain, and that there were great numbers of free negroes and several missionaries there. Nevertheless, he invaded their territory at the head of a slave-hunting force, a great part consisting of Amazons, and met with a severe defeat under its walls, on March 3rd, 1851, which is said to have greatly crippled his power. The name of Abeakhenkafa, which means ‘under the stone,’ has reference to a large natural cave within the town walls, wherein the market is held. A new species of silk from Bassa in the interior, and a peculiar description of wool, from Quotta to the westward of Abeakhenkafa, have been introduced as articles of trade into England, and are likely to prove valuable.

ABECKET, GILBERT ABBOTT, born in Golden-square, London, in the year 1810, was the son of a respectable washer, and was educated at Westminster School. He was only displayed great talent as a humorist. As early as 1825 his dramatic productions, in prose and verse, but all burlesque character, were published in Duncombe's 'British Theatre; in 1826-29 nine more appeared in Cum-
Sorophylloicae and Lamiaceae have their sepals and petals arranged with the number five. According to a very general law, in the families of these orders, the petals are all numbered, but in this case they do not. In the majority of instances the stamens are but four: hence it is said that one stamen is aborted, or there is an abortion of one stamen. The want of harmony between the parts of the flower generally is thus spoken of. In other words, whereas the stamens number six, and the seeds only one, two, or three, the remaining ovules are aborted.

In Horticulture, the premature development of the fruit, or any defect in it, is called Abortion.

ABRAXAS, a genus of Night-flying Lepidoptera, to which belongs the common Magpie Moth, A. graualirata. The caterpillar of this moth attacks the leaves of gooseberry and currant, in the beginning of the month of May. It is of a yellowish-white colour, with an orange stripe on each side, and covered with black spots. The chrysalis is black, relieved at its pointed end with orange circles. The expanded fore-wings of the perfect insect measure about one inch and a half across. The wings are of a yellowish-white colour, variously spotted with black. The fore-wings have a band of pale orange. The body is orange, spotted with black. The eggs are deposited on currant or gooseberry leaves in July or August, and the caterpillars are hatched in September. To escape destruction by other insects, they may be picked off, or dusted with the powder of white hellebore, or the leaves of the plants attacked may be burned.

ABROMA (from a and bromus, 'not fit for food,' in opposition to arum, 'for gods'), is a genus of plants belonging to the natural order Butterfiles. The species consist of small trees, with hairy lobed leaves and extra-axillary or terminal few-flowered peduncles at the tops of the branches. *Abroma augusta* is a handsome tree, with drooping purple flowers, seated on peduncles opposite the leaves. It is a native of the East Indies. The fibrous tissue of the bark of this plant is manufactured into cordage.

ABRUS (from abbr, soft), a genus of plants belonging to the papilionaceous division of the order Leguminosae. The cultivated species is *A. conicus*. The largest, legume is oblong, compressed, and 4-6-seeded. There is but one species, *A. precatorius*, which is a delicate twining shrub, with abruptly plunate leaves, bearing many pairs of leaflets. It is a native of the East Indies, but is also found in the tropical parts of Africa and America, where perhaps it has been introduced. The seeds of the commoner variety are red, with a black spot, whilst other varieties produce various coloured seeds. These seeds are in much request as ornaments among the naturalists of the continental nations. They are strong as beads, with shells, and other hard seeds. They are brought to Europe from Guinea and the East and West Indies. They are used frequently as beads for rosaries; hence the name *precatorius* given to this species. The leaves and fruits of *A. precatorius* are a considerable article of importation to India, and theS. stratiatum blossoms freely nearly all the year round, when turned out under a wall in Hampshire. *A. violifolium*, *A. venenatum*, *A. rubrense*, and *A. poonfororum*, are also tolerably hardy species. The plant known as Bencico de Deus, in the province of Rio Janeiro, in Brazil, is the *A. caesalipum*. It has large purple solitary axillary flowers, which are dressed and eaten with their viands by the inhabitants of Rio. In cultivation the species require a light rich loam and peat soil, and should be propagated by striking cuttings in sand in a cool greenhouse in summer.

ACCIPITER. [FALCONID.]

ACCINGTON, Lancashire, a manufacturing town of recent growth, in the parish of Whalley and higher division of Blackburn hundred, is situated in a deep valley surrounded by hills on the banks of the Hindburn, or Accrington brook, in 53° 45' N. lat., 2° 22' W. long., distant 19 miles N. from Manchester, 207 miles N.W. by N. from London by road, and 148 miles N.W. from Leeds by the Lancashire and Yorkshire Railways. The population of the town in 1851 was 7481. The livings are perpetual curacies in the archdeaconry and diocese of Manchester. Accrington possesses two churches of the Establishment; one, St. Michael's, a plain building; the other, Christ Church, is a spacious gothic edifice erected in 1838, at an expense of about 8000£. The Wesleyan Methodists, Independents, Baptists, Roman Catholics, and Swedewor- giists have places of worship. There are national schools, besides one or two private ladies' schools. There is a subscription library, two news-rooms, and a savings bank. The town is paved, lighted with gas, and well supplied with water. The general aspect of the town is good, and the inhabitants are said to be industrious. It is a town of the ancient borough of the county of Lancashire. It is a large place, with extensive bleach works. The neighbouring coal-mines employ many of the inhabitants.

ACERAS, a genus of Orchideaceous Plants, of which one species only is known, A. acerosus, and which is found growing in Great Britain. It is a small plant, from 8 to 12 inches in height. It has a long spike spire of greenish-yellow flowers, the parts of which are so arranged as to give them the appearance of the true orchid. It is a man : hence this plant has been called the Man-Orchis.

ACETAL. [CHEMISTRY, S. 1.]

ACETONE. [CHEMISTRY, S. 1.]

ACETONITRYLE. [CHEMISTRY, S. 2.]

ACETUM. [CHEMISTRY, S. 2.]

ACHILL, an island off the west coast of the barony of Burriehooles in the county of Mayo, in Ireland. With the adjoining peninsula of Corran Achill it constitutes the parish of Achill, and one electoral division of the Poor-Law Union of Achill. It is separated from the mainland by a narrow arm of the sea, called Achill Sound, connecting Clew Bay with Blacksand Harbour. The length from Achill Beg island at the extremity of the Sound, on the south, to Achill Head, at the Atlantic extremity of the island on the west, is 154 miles; breadth from Achill Beg on the south to Ridge Point in Blacksand Bay on the north, 134 miles. It lies between 53° 01' and 54° 55' N. lat., and 9° 55' and 10° 12' W. long. The area is 35,263 acres. The population of Achill is about 400 persons, many of whom are engaged in the whale fishery.

The island, the name of which signifies ' Eagle,' is in form nearly a right-angled triangle, of which one side extends from south to north, facing the mainland, from Achill Beg to Ridge Point; another from east to west, from Ridge Point to Blacksand Harbour; and the third side, forming a re-entrant irregular coast-line of about 35 miles, and having the Bay of Tramore about midway, is washed by the Atlantic. The surface, which is excessively wild, barren, and boggy, rises towards the north and west into mountains of 2000 feet and upwards; and at one point near the western extremity of the island, Tonaroghaun, the cliffs towards Blacksand Bay descends precipitously from the highest point of the island, forming a shelving face of rock, of the extraordinary height of 2908 feet. Achill Head, at the extreme west, consists of a narrow ridge of rock, of about a mile in length, and from 500 to 400 feet in height, the summit of which is in some places covered with the remains of a small fort. The western side is also very precipitous: the cliff at Dooega Head, which forms the eastern boundary of Tramore Bay, rises 818 feet over the Atlantic, and is nearly perpendicular.

The geological structure of the island is simple; the whole being a series of broken rocks.

Of the entire surface of Achill Island and Corran Achill, comprising an area of 51,033 acres, and inhabited in 1841, by a population of 6392 persons, there were only 544 acres under cultivation in 1845, and in 1861 the population of the parish was only 277 vaccine. The island is inhabited by the most wretched hovels huddled together without the least regularity. In the district between Tonaroghaun and Achill Head, at Boley, some of the huts still inhabited are built of drystone in the beeive form. There are three considerable villages: one at Barm, on the south-west, where there is a good boat.
produce. Orchards and vineyards are numerous; lucerne is sown to a great extent for fattening cattle and for their maintenance during the winter. In summer cattle find excellent pastures on the declivities of the mountains which however during four or five months are covered with snow. Hemp is also cultivated in some parts of the valleys. Great quantities of apples, pears, peaches, nectarines, figs, walnuts, muscatel grapes and strawberries are sent to Santiago and Valparaiso. The sugar-cane is cultivated in the valley of La Ligua, but no sugar is made, the green shoots being taken to Santiago for sale.

The hills and mountains which incline the valleys and cover by far the greater portion of the surface of the country are stony, mostly round-topped, and of gentle slope, except towards the Andes where they are steep. Their soil consists of a hard red clay, which is thinly covered with a few bushes and stunted trees, and many cactuses. The ravines present a few evergreen trees and shrubs. The nature of the soil and the scarcity of rain combine to render these hills nearly useless as pasture ground. In some places however near the coast there are some more fertile tracts, on which herds are raised without much difficulty. They may be planted in a mixture of loam and leaf-mould, with a little silver sand. They can be placed out in the summer, but require shading on hot days.

ACHYLA — A genus of Cryptogamous Plants, belonging to the class Bogaceae. It is composed of a single tuberous cell, which expands at the end into a large cell, which is cut off from the lower portion of the tube by the formation of a partition. In this enlarged cell a circulation of granular matter has been observed. In course of time cells are formed in this enlarged cell, and the outer cell eventually bursts at some spot, and allows of the escape of the enclosed cell; but before this places the cells in the interior move about, and, after their escape, exhibit for a considerable time the usual suberous plants. Some examples of the Zoospores. They soon attach themselves to some fitting object, and grow into little plants, like their parent. A similar process goes on in most of the Algae, but not so easily observed as in this case. The class which has been described is the S. protonemata, which is found parasitic upon fish and other aquatic animals. This plant is more especially developed on fish and aquatic reptiles kept in confinement. It was first observed on gold fish, but several writers have described it as existing on various animals, as the Stickleback, Water Shad, Salmon, Frog, and Newt.

ACID, ORGANIC. [CHEMISTRY, S. 2.]

ACONCAGUA, a province of Chili, in South America, lying on the coast of the Pacific ocean, between 32° 30′ S. lat. and 79° W. long. It is divided into 11 departments and 333° 30′ S. lat., 71° and 72° W. long. Its length from N. to S. is about 150 miles; towards the east the province extends to the crest of the Andes, between which and the Pacific the width is about 100 miles. The province is divided into the departments of Maule, Cauca, Cule, and Linares, which may be separated by the heavy swell which sets in from the south-west. The port of Quintero formerly had from one and a half to two fathoms water, but by the earthquake of 1822 its bottom was raised, with the adjacent coast, from four to five feet, so that it is now too shallow for vessels of any size. North of Quintero are the road-heads of Horcon and Papudo, with good landing places; and farther north the cove of Piano, from which much copper is shipped. The principal towns of the province, like most of those in Chili, are regularly built and on a uniform plan; so much so that a general description of one will suffice for all. In the centre is the Plaza or principal square, one side of which is formed by the cathedral or church and the buildings connected therewith; a second side is formed by the military or municipal offices; on the other sides, which in most instances are fronted with piazzas, are the theatre, coffee-houses, and the principal shops. The area of the Plaza serves frequently during the early part of the day as a fruit market, and vegetable market in the evening. It is the residence of promenade; and during all political and religious festivals it is the great centre of attraction. From the Plaza branch off the principal streets, straight, wide, regular, and crossed by others at right angles. The houses, as is usual in countries subject to earthquakes, are only one story high; they are built of sun-dried bricks, and in the Spanish fashion. Towards the street they present generally a blank wall, pierced only by a wide doorway or gate leading into a patio, or court-yard, on which the prin-
ADDISON'S DISEASE: ADMINISTRATION AND ADMINISTRATOR. The whole jurisdiction of the Ecclesiastical Courts in the grant and withdrawal of administrations, and the superintendence of administrators, has been transferred to the Court of Probate. (20 & 21 Vict. c. 77. [Probate, Court or, &c.]) The customs of London, York, &c., 1280, are acknowledged, and the distribution of the estates of intestates thus rendered uniform throughout England. (19 & 20 Vict. c. 94; &c.)

ADMIRALTY, COURT OF. The jurisdiction of this Court extends to the recovery of a ship, &c., where the removal of the maritime jurisdiction by the statute 9 & 10 Vict. c. 90. Questions relating to the attack and capture of pirates may now also be determined by this Court or the Vice Admiralty Courts abroad. (13 & 14 Vict. c. 122.)

ADOLPHUS, JOHN, was born in 1770 and died July 14, 1855. Mr. Adolphus was a barrister of high standing in the criminal courts, and at his decease was father of the Old Bailey bar. He was a keen advocate, a fluent speaker, and a good lawyer. His practice, previously very considerable, was highly increased by the manner in which he distinguished himself as leading counsel for Thistlewood and the other prisoners charged with a treasonable conspiracy in 1820, though he was retained on their behalf only a few hours before his conviction. Mr. Adolphus is best known as the author of the 'History of England from the Accession of George III.,' originally published in 3 volumes in 1805, but which he subsequently revised and greatly extended. Of this enlarged edition the seventh volume appeared just a few weeks after his death, and the conclusion has not been published. It is a work of considerable research and very carefully executed, but it does not exhibit very high historical powers. He was also the author of the 'Statute Law of the British Dominions in the West Indies;' 'Political State of the British Empire,' 4 vols. 1818; 'Memoirs of John Bannister;' and some fugitive pieces and pamphlets.

ADULTERY. The action of damages for criminal conversation in the case of a woman, was once an established cause in the common law, but has now, under 21 Vict. c. 85, creating 'the Court for Divorce and Matrimonial Causes.' The injured husband, in applying to this Court for a divorce or a judicial separation, may claim damages, which however can only be awarded to him by the verdict of a jury, and the Court may then direct in what manner the damages are to be disposed of; for the whole or any part thereof may be settled on the children of the marriage, as a provision for the maintenance of the wife. [DIVORCE, &c.; SEPARATION, JUDICIAL, &c.; HUSBAND AND WIFE, &c.]

ADZEMA, TADPLACE, is common throughout the whole of Europe, and grows abundantly in Great Britain. It has a stem, with leaves, having a long stalk, and three times ternate; the leaves unequal at the base and acutely serrate. It has a creeping root, and grows in damp places. Although well known, and having the names of Goat-Weed, Ash-Weed, Herb Gerard, and Wild Masterwort, it seems to possess no medicinal properties. Linnaeus says that it is boiled when young, and eaten as greens in Sweden.

ÆTHERS, SILICIC. [CHEMISTRY, &c.]

AFFIRMATION (in Law). Every person who has conscientious objections to taking an oath, may now be permitted to make an affirmation in lieu thereof, the effect of which is the same as if the testimony were given on oath. (Common Law Procedure Act, 1854.)

AFFRE, DENIS AUGUSTE, archbishop of Paris, was born in 1805. At an early age he evinced a desire to devote himself to the Church, and he became a student at the seminary of St.-Silpice. He was ordained priest in 1818, and discharged a variety of ecclesiastical functions till he became archbishop of Paris in 1840. Although in less of study and learning, and the author of several treatises (amongst which was one on Egyptian herioglyphics), he would scarcely have found a place in the history of his times, but for the lamentable circumstance of his death on the 27th June, 1848. Paris was then in a condition of fear, either between the solider and a vast body of insurgents. The archbishop was induced to apply to General Cavaignac, proposing to stand between the contending bodies as a messenger of peace. The general told him that the course was full of danger. "My life," he replied, "is of small consequence. Some hours afterwards the firing of the solildry having ceased at his desire, the archbishop mounted a barricade erected at the entrance of the Faubourg St.-Germain, which he held for a short time, in the dress of a national guard, wearing a workman's dress, carrying in his hand a green branch as an emblem of peace; and he had at his side a faithful servant named Pierre Sellier. The devoted man, having been received with the confidence that he expected to inspire. Some indeed of the combatants sternly rushed out their hands, but others remained silent, while others groaned and hooted. The prelate endeavored to speak a few words; but the insurgents, fancying themselves betrayed, threw a stone at Gardes Mobiles, who then fired an volley. He fell. Then a cry of horror went up from the crowd, and many, even of the insurgents, rushed to his aid. Albert and Sellier were leading him away, when Sellier was also struck by a ball. The insurgents who surrounded the archbishop rushed out through the barricade to the house of the Mahaut, and that they would avenge him. "No, no, my friends," he replied; "there has been blood enough shed; let mine be the last that is spilt." He was carried to the archiepiscopal palace, and died the same day. The National Assembly issued a decree announcing its profound grief at the event of his death, and his public funeral took place on the 7th of July, amidst the deepest feelings of popular regret. (Nuova Biographie Universelle, 1852.)

AFREIDIES, NED, was spoken of under the more general name of Kyburees, inhabit the Kyber hills on the confines of Cabul and the Punjab. They command the passes in these hills, for a safe conduct through which their Malikus, or chiefs, consider themselves entitled to the fee of fifteen cents for each man, and of twenty-five for each欧洲人, which was formerly paid by the rulers of Cabul, and the non-payment of it after the restoration of Shah Soojah to the throne excited the furious hostility of the Afreidies against the British in Cabul. They repaired the march of Colonel Wade and the Sikh auxiliary through the hills of Cabul in July, 1839, but were compelled to evacuate the fort, Ali-Musjid, the key of the pass, which, with other posts between Peshawur and Jelilasabad, was garrisoned by small detached parties. At the conclusion of the Afghan campaign in 1849, they defeated two Sepoy regiments advancing under Brigadier Wild from Peshawur to the relief of two other Sepoy regiments under Colonel Mosesley in Ali-Musjid, which had seized that fort some days before, and had been robbed of their provisions on their way. Cut off from all communication with the brigadier, and short of provision, Mosesley evacuated the fort on the 24th, which was immediately seized by the Afreidies. On General Pollock's advance from Peshawur to the relief of Jelilasabad, in the spring of 1849, the Afreidies were expelled from the Cabul valley, and their capital was declared to be Daka for 50,000 rupees; but Pollock chose to force his way, sweeping the heights on each side of the defile with his light troops, whilst the main body advanced through the pass and took the hard climb up the mountains across the entrance. Before Pollock reached Ali-Musjid the Afreidies had evacuated it; it was then held by a strong force till the final withdrawal of the British troops from Afghanistan, when it was blown up. We next hear of the Afreidies in connection with another pass on the road from Peshawur to Kohat, leading to the Salt Range. On February 2, 1850, about 1000 Afreidies plundered the camp of a party of British Sappers employed in making a road through this pass, about 16 miles south from Peshawur, and killed several of the men. To avenge this massacre a strong force, under Colonel Bradshaw, scoured the hills in the neighbourhood, destroying six villages and a great number of the enemy, who however made some resistance on the return of the troops through the ranges.

To the west of the Kyber hills, on the Cabul side, the Momund clan dwells along the banks of the Cabul River. Their chief place, Laipoorah, the residence of the Malik, is opposite Daka

AFRICA. At the period when the article Arance in the 'Penny Cyclopedia' was written, the descent of the Quorra, or Niger, had recently been accomplished by the brothers Richard and John Lander. In a subsequent article, Quorra, additional details are given respecting the river and the countries through which it flows, and its extent, brought down to the year 1840. At that time an expedition was in preparation by the British government, the object of which was to chart and supersede the foreign trade in slaves by the establishment of a commerce along the banks of the Quorra, which should be more beneficial to the native chiefs.
than the cruel traffic in slaves. This expedition, consisting of
three store-vessels, began the ascent of the river in 1841,
but a fatal sickness unhappily seized the greater part of
the crew and officers, and they were unable to ascend the
river so far as it had been previously reached by the disastrous
expedition of 1832. The failure of these two expeditions,
attended as they both were by a fearful loss of life, pre-
vented any renewal of the attempts to ascend the Quorra
till the year 1854, when Dr. Bakie made his successful
ascent of the river and its great eastern tributary, the
Tchadda or Benue. This ascent was made in Mr. McGregor's
launch, the Plied, fitted up and provided with a par-
allel construction suitable for ascending a shallow river against
a powerful current. In the first instance Lieutenant Lyons
McLeod, R.N., was to have had the command, his project of
exploring the Niger between the Tchadda and the Gambates
having been abandoned; but afterwards Mr. Befcroft, already
well acquainted with the Quorra, was appointed the chief.
Mr. Befcroft, however, died before the Plied had reached the
mouth of the river, and the command was then assumed by
Dr. Bakie, surgeon, R.N. The expedition occupied about
four months, from July 12 to November 7, and ascended
250 miles of the course of the Tchadda above Dagbe, which
was the farthest point reached by Allen and Oldfield
in 1832, and is about 100 miles from the confluence of the Tchadda and the Tchad. This point, reached by Dr. Bakie's
expedition, was only fifty-five miles from the place where Dr. Barth
afterwards crossed the Benue, thus proving that the Benue of Central Africa is the same river as the Tchadda. Dr. Bakie
is (I believe) engaged in another similar expedition,
in which he hopes to reach the Tchad itself, though possibly
a still higher point. He had ascended the Quorra to some distance
above Rabbu, where his steamer was wrecked by striking
on a sunken rock in the bed of the river. All the persons,
having been saved, and they had entered into friendly
relations with the natives. A new steam-vehicle, suitable for navigating the Tchadda, has been sent out to
replace the one which has been lost.

We now proceed to notice the discoveries made in the south-eastern part of the continent since the publication of the article Aruaca, in the 'Penny Cyclopedia.'

In the years 1835 and 1836 Dr. Andrew Smith made a
journey in South Africa, during which he visited the sources
of the rivers Caledo, and Maputa, ascended the mount-
tains of Caffraria, and advanced in the tracks of the traders as far north as the Tropic of Capricorn. He was
unsuccessful, however, in the principal object of his journey, which was to find a passage between the Niger and Nyasumi, since discovered by Messrs. Livingstone, Oswell, and
Murray. In 1836 and 1837 Captain J. E. Alexander ex-
cplored the countries inhabited by the Namaquas, Bushmen, (Boesemans), and Hill Damaras, extending on the western side of the Cape Colony to 58° S. lat., near the river Nourse on the north, and as far inland as 21° E. long. Through this journey we obtain a description of the Damara people, who, though a race of fine
 stature, are in a low moral state, and likely to be extin-
cuted by the more civilized and advanced tribes of the central
neighbours on the north, the Ovampo. The high table-land,
which was traversed to reach the Ovampo, is cut through by
deepest ravines, the chief of which serve as escapes for the
periodical floods of the rivers. In delineating the moral
character, as well as the physical conformation of the
different tribes of South Africa, it is interesting to observe,
from the observations of Mr. Galton, how their differences
are connected with the form, subsoil, and vegetation of their
respective lands. Thus, the arid inland plateau, covered
only with thick jungle and short brushwood, hold the dwarfed
and sinewy Bushmen; the more open, hilly, and undulating
pastera-lands, the Damaras; whilst the rich corn-lands on the
north are occupied by the race which is the most cultured
and advanced, the Ovampo and Ondongas, the capital of this
people, is estimated to be about 70 or 80 miles to the south
of the great river Amorongho Achilulas, the Nourse of our
maps. The table-land inhabited by the Damaras rises in the points to 5000 and 6000 feet, and at the time
Mr. Galton was there, in September and October, 1851, pro-
ceded as far eastward as Tounious, a distance of 600 miles
from the coast, on the road to Lake Ngami, distant about 180 miles. Mr. Galton did not reach Lake Ngami, having
expected it to be at least 70 miles nearer, but when he arrived at a place which he supposed to be Lake Ngami, which
was expected, and the specified time not allowing him to
remain longer. Mr. Anderson however afterwards
proceeded again to Tounious, and thence to Lake Ngami,
from which he ascended a distance, and the river Teouguie, the
principal affluent of Lake Ngami. Mr. Anderson also
reached the Lake at the end of July, 1853. Mr. Galton and Mr.
was estimated at a little over 20000 feet, and they had
described it in their travels to 11 from Kolobeng.
The latitude of the upper end of the lake is 20° 20' S., and the longitude probably between 23° and 23° E.
The lake receives the Teouguie, a large river, at the north-
western end, and discharges itself by the Zouga at the north-eastern end. Lake Ngami is about 70 miles
from the Teouguie, which, as well as the Teouguie, flows
from the north. The Zouga continues for a consider-
able distance to be a fine river, broad and deep, with
beautifully wooded banks, but receiving no more affluent,
and therefore having lost the richness of its channel, as its
distance from Lake Ngami becomes very low, and the rivers
are dried up. The water begins to flow again in April, but
makes little progress in filling Lake Kudumulu till the end of
June. The Batswana tribe of natives live at the eastern end
of the lake, where they have their principal village. After
a short stay there, the party returned, and arrived at Kolobeng,
October 10. There are prodigious numbers of the
elephant, rhinoceros, and other large animals, in the vicinity
of the lake and its rivers. The name Ngami is pronounced
by the natives at the end of some name. Mr. Galton
made another short visit to Lake Ngami in 1850, accompanied
by his wife and three children.

In June, 1851, Dr. Livingstone, accompanied by Mr.
Oswell, again started for the north. The two parties
separated, and they succeeded in pushing their researches northward to 17° 25' S. lat., and between 24° 30' and 26° 50' E. long., traversing a consider-
able tract watered by deep and constantly flowing streams.
They passed over a large salt incrustation of about 100
miles in length and 15 miles in width, and saw many others
lying to the north of the spot where the Zouga terminates.
Considerably to the north of these great natural salt-pans,
and not far from the river Nyasumi, the Zambesi, the inhabitants are more intelligent than most of
the native tribes of South Africa.
Anderson have each published a volume giving an account of their travels.

We shall now give an account of the missionary explorations from the eastern coast, and of the expedition to Central Africa.

The zealous and enterprising missionaries, Kräpf and Rehbmann, stationed at Rabbai 'Mpija, near Mombasa, in about 4° 5.30' S. lat., began their journey into the interior of the country in November, 1847. That year Mr. Rehbmann penetrated westward to Teita, a "country whose mountains rise to such a height out of the vast surrounding plains, that on some eminences near Rababi 'Mpija they are to be seen at a distance of 5 or 6 miles, and with the glass mounted on a gun, the same missionary performed a journey farther into the interior, to the still more elevated country of Djagga, where, at a distance of rather more than 200 geographical miles from the coast, in a direction about W. 30° W. from Mombasa, he made the remarkable discovery of a lofty mountain, named Kilimanjaro, of which the summit is covered with perpetual snow. The existence of snow on Kilimanjaro has been disputed in Europe, though it is difficult to say on what reasonable ground. On subsequent journeys, both Mr. Rehbmann and his colleague Dr. Kräpf satisfied themselves of the fact; and unless it be intended absolutely to impugn their veracity, their evidence cannot be rejected.

In April, 1849, he again set out on his way into the interior, both with the object of gaining further indications of the existence of the unknown mountain, and December of the same year Dr. Kräpf successfully penetrated as far as Ukambani, a country situated northward of Djagga. Of the geographical results of this journey, one of the most important is the discovery of another snowy mountain, named Kilima-njaro. The mountain was discovered to the south for the first time by the Reverend Mr. Rehbmann's map ("Church Missionary Intelligencer") is published in 1° 8. lat., 25° 10' E. long., at a distance of 320 geographical miles north and 65 west from Mombasa. This position, observed to two immense towers, one of which, as you may call them. These horns or towers, which is a short distance from each other, give the mountain a grand and majestic appearance, which raised in my mind overwhelming feelings. Kilimanjaro in Djagga has a dome-like summit; but the mountains of the former are formed of two horns rise like two mighty pillars, which I have no doubt are seen by the inhabitants of the countries bordering on the northern latitudes of the equator. Still less do I doubt that the volume of water which Kefina issues to the north runs towards the basin or, on a subsequent journey, both Mr. Rehbmann and his colleague Dr. Kräpf satisfied themselves of the fact; and unless it be intended absolutely to impugn their veracity, their evidence cannot be rejected.

On the 13th of June they set off for Ghat, which they reached on the 18th of July. The most interesting result of this journey to Ghat is the great number of fresh discoveries were made in this journey, but some further information was collected respecting the river which flows from the Kefina (Ndukenia or Kireina) northward, and forms most probably one of the head-waters of the Nile.

The expedition to Northern and Central Africa, conducted by Mr. Richardson, accompanied by Drs. Barth and Overweg, is one of great importance. This expedition originated with Mr. Richardson, who, after having returned from his travels in the northern portion of the Sahara in 1845 and 1846, induced the English government to send him out for the purpose of concluding commercial treaties with the chiefs of the desert-regions between Tripoli and Lake Chad. Through the lively interest taken in it by Chevalier Bunsen, Baron Humboldt, and Professor Ritter, it was arranged that Dr. Barth and Dr. Overweg, two Germans, should accompany Mr. Richardson for the purpose of making scientific observations. Lord Palmerston sanctioned this expedition, and afforded the two travellers pecuniary assistance, in addition to the money sent by the Geographical Society in Berlin this King of Prussia.

The three travellers departed from this country at the latter end of 1849, and arrived in Tripoli in the beginning of the year 1850. They journeyed throughout the mountainous region to the south was thoroughly explored and surveyed by the two Germans with a radius of 60 to 80 miles from the town. [Tripoli.] An unexpected degree of cold was experienced in these excursions. On one day the thermometer, before sunrise, stood as low as 50° Fahrenheit, and on the 2nd and 3rd of February, the snow obliged the travellers to remain in their tents. After their return to Tripoli, several weeks were required for their preparations; and the transport of a boat for navigating Lake Chad caused considerable difficulty. For this purpose a beautiful wherry had been constructed by the direction of the admiral at Malta, broad in the beam, and very light on water; but it was necessary to take it to pieces, and several camels were requisite to convey it across the burning sands of the Sahara.

The travellers started at last on the 24th of March, 1860, the great caravan having departed before them; but the party formed a small caravan of itself, having about 40 camels and mules. The required assistance was rendered by her Majesty's consuls in Tripoli and Murzuk to the undertaking, so that the expedition started under the most favourable circumstances.

The direction of this town, Murzuk was almost due south from Tripoli, beyond the Obarian defile, the country consisting of a continuous table-land, of an average elevation of 2000 feet. As far as the well of Taboniyah, many deep wadies intersect this table-land, and the ruins of several Roman monuments and cisterns were discovered by the travellers. Southward of that place is a table-land, or Hamadah, an immense desert of considerably greater elevation, and extending for about 110 geographical miles in the same direction. As far as the eye can reach, neither trees nor vegetation can be seen; and the BOXU of Dot-ḷ in which occurs is only found scattered in the trifling irregularities of the surface. The ground is covered with small stones, pyramids of which, erected with great labour, serve as roadmarks to the intrepid camel-drivers by day, while the polar movements of the sun are indicated. On the 8th of July, after six days the expedition reached the southern edge of this table-land, which descends in perpendicular walls to the Wadi el Helai. Following the descent for about 60 geographical miles, the travellers came to the Wadi Shabiti, over another plateau of equally dismal aspect. It is composed of a black sandstone, the disintegration of which forms a dark yellow sand, covering the inequalities of the stony surface, from which stands out prominently the black rock, in high contrast with the light relief of the basaltic rocks. They reached Murzuk on the 8th of May, and remained there till the 13th of June, collecting much important information respecting the countries and nations to the south. Murzuk is very unhealthy and dangerous for Europeans, but happily none of the party suffered during their stay.

On the 13th of June they set off for Ghat, which they reached on the 18th of July. The most interesting result of this journey to Ghat is the great number of fresh discoveries were made in this journey, but some further information was collected respecting the river which flows from the Kefina (Ndukenia or Kireina) northward, and forms most probably one of the head-waters of the Nile.

Lord Palmerston sanctioned this expedition, and afforded the two travellers pecuniary assistance, in addition to the money sent by the Geographical Society in Berlin this King of Prussia.

The three travellers departed from this country at the latter end of 1849, and arrived in Tripoli in the beginning of the year 1850. They journeyed throughout the mountainous region to the south was thoroughly explored and surveyed by the two Germans with a radius of 60 to 80 miles from the town. [Tripoli.] An unexpected degree of cold was experienced in these excursions. On one day the thermometer, before sunrise, stood as low as 50° Fahrenheit,
forms. From Ghát the general surface of the country
continues to rise, and at Seluñet the travellers saw
around them masses of mountains, and their journey
began to be more adventurous. After the middle of August they experienced the influence of the
Soodan rains; the atmosphere then beginning to be
humid, and the evenings or mornings being accompanied
by fog. Frequent thunder-storms and heavy rains also
occurred, which caused the banks of the rivers and
the wādīs became completely changed, luxuriant plant-
ations of palms being everywhere met with to the south of
Taghajjīt. According to the natives the rainy season lasts
until the 30th of September. At Soodan the so-called
rain season is called the sogh and dagg; the former,
when the rains come in May and June, is mild and
placid, and the latter, from the beginning of July until
the 22nd of July, is violent and destructive.

On the 11th of September, 1851, Dr. Barth set out on
an expedition to Kānem, a district on the eastern side of Lake
Tchad. On the 18th of September Dr. Overweg joined Dr.
Barth, and after a short halt at Kukā, on his return from
the Shāry, they arrived at Lake Tchad on the 22nd of September.

On this expedition Dr. Barth had a favourable opportu-
nity of investigating Lake Tchad. It is a vast lagoon without
any communication with the sea, and is history is the
harbour of Kukā, the capital of the Shāry, from which
they returned October 14, after having been exposed
to much danger from hostile natives.

On this expedition Dr. Barth had a favourable opportu-
nity of investigating Lake Tchad. It is a vast lagoon without
any communication with the sea, and is history is the
harbour of Kukā, the capital of the Shāry, from which
they returned October 14, after having been exposed
to much danger from hostile natives.
The rains had then commenced, and the river was over 1000 yards wide, very deep, and flowing at a rate of about three miles an hour. He crossed the Logon or Linyanti at the 15th of August, and arrived at Kuka on the 1st.

On the 20th of September, Mr. Overweg died of an attack of fever. This date closes the 3rd volume of Dr. Barth’s Travels and Discoveries in North and Central Africa, 3 vols. Lon., 1835. Mr. Overweg, who came to Timbuctoo in August from the north, recovered and proceeded to Mechoula, and thence to Timbuctoo, which he reached October 12, 1840. 

In February, 1853, Dr. Edward Vogel, a young German, employed at Mr. Bishop’s Observatory, Regent’s Park, Lon., was sent to join Drs. Barth and Overweg. He was accompanied by two volunteers from the corps of Sappers and Miners. They reached Lake Tchad on the 6th of January, 1854, and were received kindly by the sheikh and his uncle. Dr. Barth was then absent on his journey to Timbuctoo. Dr. Vogel was stated to have been put to death by the Sultan of Waday, and his papers have not yet been recovered, nor his fate ascertained with certainty. One of the Sappers and Miners has returned to England; the other, General Maguire, appears to have been assassinated in the recent troubles. It is hoped that the stories of his explorations, had visited Yacoba, and on the 3rd of April, 1855, had crossed the Tchadda at the place where Dr. Bisatie had been, in the Pielied steamer, in 1854.

In January, 1855, accounts were received by the Royal Geographical Society that the Linyanti, which were subsequently confirmed in April, of the successful issue of a commercial journey across the continent of Africa by a Moorish caravan, basing for ivory and slaves. It had started from Zanzibar on the east coast (6th S. lat., 26° 8’ long), and had reached the Benega on the west (12th S. lat., 15° 5’ E. long). The journey occupied six months; a day and a night were occupied in crossing the great lake of Tanganyia, also called Zambesi, Zewa, and Maravi. In one part of the journey no elephants could be found.

We now proceed to give an account of Dr. Livingstone’s long and hazardous journeys from the interior to the west and east coasts of Africa, the greater part of which were through countries never before seen by any European. 

In April, 1852, Dr. Livingstone proceeded to Cape Town, with his wife and children, and sent them home to England. He then returned in order to explore the country in search of a healthy district, which might prove a centre of civilisation, and of a connection with the West Coast of India. When he reached Kuruman, on his return, he learnt by a letter from the chief Sechelle that the natives had been attacked at Kolobeng by the Boers of the Casan Mountains; that the village of Kolobeng had been burnt, and that the cattle had been destroyed. The children of the school children carried off for slaves, and his own residence plundered of everything.

Having returned to Kolobeng, and remained a few days with the wretched Bakwaine, he proceeded northwards on the 15th of January, 1853. The Bamangawo Hills, between Kolobeng and Lake Ngami, are part of a range called Bakasi, which rises about 700 or 800 feet above the plains, and is composed of great masses of black basalt. This mass of basalt, about six miles long, is tilted up towards the rocks both on the east and west. Passing on to Letchofo, about 20 miles beyond the Bamangawo, they found a fine supply of water. This spot was Mr. Gordon Cumming’s former station north. Farther on they came to the hill Nyasa, 15° 27’ 30” S. lat., 24° 13’ 26” E. long. It is 300 or 400 feet high, and was the only hill they had seen since leaving the Bamangawo Hills. As they approached Linyanti, they found the river-beds filled by the annual inundation, and flushed with the overflow from the Linyanti, with the rise of the Leembe. With some difficulty they reached Linyanti, May 23, 1853. Linyanti is the capital town of the Matabele, and is situated in 18° 17’ 20” S. lat., 23° 50’ 9” E. long.

The chief of the Makololo, named Sekeletu, a young man of 25 years of age, and head of the nation of Matabele, numbering 7000 or 9000, received Dr. Livingstone, whom they were expecting, with enthusiastic welcome. The Makololo are the most northerly of the Bantuans.

Having waited a month at Linyanti, Dr. Livingstone, attended by a party of the natives, set out from Shesheke,
to Loanda, on the west coast of Africa, as soon as the cooling influence of the rains should be felt in November.

He had few scientific instruments, but they were of the best kind—a sextant by Troughton, a chronometer by Dent, a thermometer by Dollond, and a compass from the Cape Observatory, and a small telescope.

On the 11th of November, 1833, he left the town of Linyanti, accompanied by Sekeleku and his principal men, to embark on the Chobe. They crossed five branches. With this branch they entered the deep river. The banks are of soft calcareous tufa, like those of the Zonga. The bed is deep, and the sides perpendicular. The course is extremely tortuous.

The ascent of the confluence of the Chobe with the Leembybe is ill defined, on account of each dividing into several branches before they unite, but when the whole body of water collects into one bed, it is very wide, and is a goodly sight for one who has spent many years in the thorny south. Turning round they began to ascend the Leembybe, and on the 19th of November reached the village of Shesheke. After a short stay they proceeded up the Leembybe. Their progress was slow, owing to their waiting at the different villages for food.

Dr. Livingston having once been on the way to the west coast, was accompanied by a band of 27 men, belonging to the Makololo. It was the dry season. Parts of the river were only about 200 yards wide, and very deep. In other parts it is spread out, bordered by woods, and the water flows rapidly over the rocky bottom. It requires great skill and care to manage the canoes in these shallow parts. The rapids are caused by rocks of dark-brown trap, or of sandstone stretching across the stream. In some places they form miles of the rocky bottom bordered with woods. The capital town of the Makololo, and is situated on a mound like the rest of the villages in the Barotse valley.

On the 27th of December, 1833, they were at the confluence of the Leeba and Leembybe, 14° 10' 52" S. lat., 23° 35' 40" E. long., and the confluence of the Leembybe with the Leembybe tunya there are many long reaches where a vessel equal to the Thames steamers plying between the bridges could run as freely as they do on the Thames. It is often, even here, as broad as the river at London Bridge, and perhaps a little deeper. There are, however, many and serious obstacles to a continued navigation for hundreds of miles at a stretch. About ten miles below the confluence of the Loeti, for instance, there are many large sand-banks in the stream; then there are a hundred miles to the river at Simah, where a Thames steamer could ply at all times of the year; but, again, the space between Simah and Katima-Molelo has five or six rapids, with cataracts, one of which, Gonye, could not be passed. At this point the water increases rapidly, and there are reaches of quiet and deep water of several miles in length. Beyond Katima-Molelo to the confluence of the Chobe there are nearly 100 miles again of a river capable of being navigated in the same way as in the Barotse valley.

On the 3rd of January, 1834, they crossed the Leeba and the Leembybe. The water is black in colour as compared with the Leembybe, which here assumes the name of Kabombo. The Leeba flows placidly, and, unlike the main river, receives numbers of little rivulets from both sides. It winds slowly through the most luxuriant meadows, each of which has a soft sedgy centre, a large pond, or else a gentle riffle flowing down the middle. The meadows are probably inundated, as the trees are on spots elevated three or four feet above the meadows. The rains were continuous, and the travellers were quite drenched.

When they had ascended somewhat more than one-third of the Leeba, they left the river, and travelled overland on the eastern side by the village of the chief Shinte, till they came to the Lake Dilolo. On their route they crossed several affluents of the Leeba, and travelled over extensive plains, much of which was under water.

On the 20th of February, 1834, they reached the small end of the Lake Dilolo. Dr. Livingston, being exhausted by the journey, could not walk or ride the whole day. After passing a little farther to the N.W., they came to river, which flowed northwards into the fine river Kasai, or Loké, which has a northern course, while all the rivers they had previously passed flowed southwards; thus showing that the flow of the Lake Leembybe is from an elevation on the north flat which forms the water-parting of the streams that flow to the north and south respectively.

On the 4th of April they reached the banks of the Quango (Coango), a river 160 yards wide, and very deep. This fine river flows among extensive meadows clothed with gigantic grass and reeds, in a direction nearly north. They crossed it after a dangerous contention with the natives, and passed on westwards to the village of Cassange (from which name), which is the farthest station known of the Portuguese. They were now safe, and in the kingdom of Angola. Cassange is situated in 9° 37' 30" S. lat., 17° 49' E. long. The distance to Loanda is about 300 miles. On the 14th of May they reached the village of Quango, 15° 12' S. lat., 15° 30' E. long., and on the 31st of May arrived at Loanda. St. Paul de Loanda has been a very considerable city, but is now in a state of decay. It contains about 12,000 inhabitants, most of whom are people of colour. It possesses two churches, one of which, formerly used for a workshop. The forts are in a good state of repair. The Portuguese bishop of Angola resides at Loanda, and was very kind to Dr. Livingston. The harbour is formed by a low sandy island, between which and the mainland is the stile for ships. There was not a single English merchant there, and only two American merchants. Mr. Gabriel, the British commissioner for the suppression of the slave-trade, treated Dr. Livingston with great kindness and hospitality.

On the 22nd, September, 1834, Dr. Livingston and his party of Makololo departed from Loanda on their return to Linyanti. They passed round to the mouth of the river Bengo, and ascending that river, arrived at Ileilo i Bengo, and on the 28th of September at Kalungwemo, on the same day they crossed the river Luapula, which flows from coffee, and sugar is also cultivated. Dr. Livingston proceeded in a canoe down the river Lucalla to Massangano. The river is about 85 yards wide, and navigable for canoes from its confluence with the Coanza to about six miles above the point where it receives the Lucalla. Massangano lies on a tongue of rather high land formed by the left bank of the Lucalla and right bank of the Coanza. It has more than 1000 inhabitants. The latitude is 9° 37' 46" S. The fort is small, but in good repair. The land on the north side is well cultivated by a Quissana Kishone, an independent tribe whom the Portuguese have not been able to subdue. Returning to Golo Alto he found several of his men ill of fever.

On the 14th of December, Dr. Livingston and his men, having recovered from severe attacks of fever, proceeded to Ambaca, 9° 16' 32" S. lat., 15° 22' E. long. On crossing the Lucalla they made a detour to the south in order to visit the famous rocks of Pungo Adongo, the fort which stands 9° 45' 14" S. lat., 16° 30' E. long. It is situated in the midst of a group of curiously angular-shaped rocks, each of which is upwards of 300 feet in height. They are composed of conglomerate in a matrix of dark red sandstone, and rest on a thick stratum of brown sandstone, with very few trees. On the 3rd of January they crossed the Cambambe, to the east of which the navigation of the Coanza reaches, is reported to be thirty leagues below Pungo Adongo.

On the 1st of January, 1835, they started from Pungo Adongo in a prairie along the right bank of the Coanza. On reaching the confluence of the Lombe, they left the river, and proceeded in a north-easterly direction. Passing over the heights of Talama Mengongo, 9° 42' 37" S. lat., 17° 27' E. long. (Jan. 16), they arrived again at Cassange.

On the 28th of January they crossed the Quango in canoes. Having reached the eastern side of the river, they ascended the eastern declivity which bounds the Cassange valley, and found it to be 6000 feet above the level of the sea, the bottom of which is at least 2000 feet below the Coanza. It is a deep but narrow stream, by a bridge. It is the boundary of Londa on the west. On the 20th of March they crossed the Chikapa, and then the Kamane, an affluent of the Chikapa, coming from the S.S.W. On the 30th of April they reached the Lomiau, where they had to cross the river.

On the 7th of May they arrived at the Moamba, a stream 30 yards wide, which they crossed by canoes, and arrived at Cabango, a village on the banks of the Chihombo, in 9° 31' S. lat., 20° 51' E. long.

On the 30th of May they left Cabango, and on the 28th reached the village of the chief Bango, 12° 29' 55" S. lat., 20° 58' E. long. On the 30th of May they left the village of Bango, and proceeded to the river Loembe, which they crossed February 1836. Having passed the Loembe, they reached (June 2) the village of Kawawa, who wished to detain them, but borrowing one of his hidden canoes by night, they crossed to the southern bank of the river Kaali.
After leaving the Kasi, they entered upon the extensive level plains which they had formerly followed. On the ist of June they forced the Lotemba, there about a mile wide, and deep, and regained their former path. It is a N.W. of Lake Dilolo, and seems to flow from it northwards, and enter the Kasi, whilst another river Lotemba flows from the other end of the lake southwards. Thus, this little branch joins the large one, and the other becomes tributary to the Kasi, and another to the Zambezi, distributes its waters to the Atlantic and Indian Oceans. From these elevated plains all the rivers seem to unite in two main drains, the one flowing to the north, and the other to the south. The northern drain is known thus far as the Linyanti, one, with men well acquainted with the rapids, by passing down the left bank, and coming into one of the stream in the eddies and still places caused by many jutting rocks, brought him to an island situated in the middle of the river, and on the edge of the lip over which the water falls. The water was low. If it had been high, it would have been impossible to have reached the island without being precipitated down the Falls. But though they had reached the island, and were within a few yards of the edge of the Falls, one could perceive what the last body of water went; it seemed to have lost itself in the earth, opposite lip of the fissure into which it disappeared being only 80 feet distant. Dr. Livingston could not comprehend it, until, creeping with awe to the verge, he peered down into a large rent which had formed in the bank of the river, and saw that a stream of 1000 yards breadth leaped down 100 feet, and then became suddenly compressed into a space of 15 or 20 yards. The entire falls are simply a crack made in a hard basaltic rock from the right to the left bank of the Zambezi, with a din like that of leaves being rubbed together, which is heard miles of miles. In looking down into the fissure on the right of the island, nothing is seen but a dense white cloud, which at the time had two bright rainbows on it. From this cloud rushed up a great torrent of vapour exactly like steam, which mounted 200 or 300 feet high. There condensed, it changed its hue to that of dark smoke, and came back in a constant shower, which soon wetted them to the skin. On the left of the island the water is seen at the bottom, a white rolling mass moving in the narrow fissure, and the branches off near the left bank of the river. The walls of this gigantic crack are perpendicular, and composed of one homogeneous mass of rock. The edge over which the water falls is partly worn and broken, so as to have a serrated appearance. The other edge is more like a cliff, except at the left corner, where a rent appears. The rock is dark brown in colour. The columns of vapour are evidently formed by the compression suffered by the force of the water's own fall into the narrow space. The upper part of the falls, which were on the right side of the island, and two on the left, and these were larger than the central column. It was low water in the Leembe, but there was a flow of 500 or 600 yards of water, which at the edge of the falls seemed at least 3 feet deep. Further down the span of the river was much deeper. Dr. Livingston could not obtain an observation of the moon to determine the position of the Falls, but that of Kalai, about 10 miles N.W. from the Falls, is 17° 51' 54' S. lat., 25° 41' E. long.

Sekelita and his large party having conveyed Dr. Livingston thus far, and furnished him with 114 men to carry the elephants' tusks to the coast, on the 20th of November, 1855, he bade adieu to the Makololo, and proceeded northwards to the river Lekone. Both the Lekone and the Leembe flow towards the centre of the country; so that it was obvious that they were then ascending the farther they went eastward. The country around was very beautiful, and was once well peopled with the tribes called Botoko, who possessed large herds of cattle. There is abundant evidence that a vast freshwater lake once existed in this part of Africa, extending from about 17° to 21° S. lat., and 22° to 26° E. long. The Borotse valley was another similar lake. These lakes were let out by means of cracks or fissures made in the subjacent mass of the country. The fissure made at the Victoria Falls let out the water of this great valley, and left a small patch in what was probably its deepest part, and is now called Lake Ngami. The Falls of Gouve furnish an outlet to the lake of the Gorongosa valley, and so of the other great lakes of the remote times. The party travelled in a direction E.N.E., leaving the Zambezi a considerable distance to the south. From the 5th of November to the 18th of December, they crossed several rivers flowing southwards into the Zambezi, and

covered with trees. The tops of the columns at that distance appeared mingled with the clouds. They were white below, and higher up became dark, so as to resemble smoke very much. The banks and also the islands scattered over the river were adorned with abundance of trees and other vegetation of various kind of form and colour. No one can imagine the beauty of the scene from anything witnessed in England. The only want felt is that of a look back in the beautiful country they had already crossed. Instead of lofty snow-clad mountains appearing to conjure the speculatives, there were extensive plains, over which a person might travel a month without seeing anything higher than an ant-hill or a.
passed on their route numerous villages inhabited by the Batoks. On the 18th of December they reached the bank of the Kafue, a river upwards of 200 yards wide, and full of hippopotami; there they encamped for the night. Their camp was four miles to the east of the Kafue. It was a very considerable distance above the Victoria Falls. There were vast numbers of water-fowl.

January 14th, 1856. The party reached the confluence of the Kafue with the Zambesi. They were met by the remnant of a church, with a broken bell, having the letters I.H.S. and a cross, but no date. The church stands in 16° 37' 22" S. lat., 30° 32' E. long. This was at Zumbo, which is situated in the angle of the confluence of the two rivers, and was formerly a considerable place, and only 32 miles north of the Zambesi. From this point the merchants had water communication in three directions beyond, namely from the Loangwa to the N.N.W., by the Kafue to the W., and by the Zambesi to the S.W. Their attention, however, was chiefly attracted to the north, or Lunda, and the principal articles of trade were ivory and slaves. It was a Portuguese colony, and, like the rest, military. The Zambesi is very broad here, about 1300 yards, and contains many inhabited islands.

January 24th they crossed the Loangwa in a canoe, and on the 24th of January passed in canoes from the north bank of the Zambesi to the south. They then proceeded at some considerable distance from the bank of the river.

On the 29th they arrived at the Portuguese settlement at Tetè (16° 9' 3" S. lat., 33° 28' E. long.), and were very kindly treated and received by the commandant. The village of Tetè is built on the south side of the Zambesi, on a long slope down to the river, the fort being close to the water. The roof is thatched with grass. The rock, on the top of the slope are much higher than the fort, and of course command it. The whole of the adjacent country is rocky and broken, but every available spot is under cultivation. The stone houses are cemented with mud instead of lime, and thatched with grass. In the neighborhood there are about 30 or 50 stone houses; the rest are native, and of wattle and daub. The population is about 4500. Only a small proportion of these live on the spot, the majority being engaged in agricultural operations in the adjacent country. Generally there are not more than 2000 resident; for, compared with what it was, Tetè is now a ruin. The fort of Tetè has been the salvation of the Portuguese power in this quarter. It is a square building.

On the 22nd of March they left Tetè, and sailing down the river, arrived at Senna on the 27th (17° 27' 1" S. lat., 30° 10' E. long.). It was found to be 523 hours sail from Tetè. Dr. Livingstone thought the state of Tetè quite lamentable, but that of Senna was much worse. The fort, built of sun-dried bricks, was in a wretched state. The village of Senna stands on the right bank of the Zambesi.

The Zambesi at Mazaro, where the delta begins, is a magnificent river, more than half a mile wide, and without islands. The delta is an immense flat, covered with high coarse grass and reeds.

Sailing down the branch of the river on which Kilimanjo stands, they reached that village, it being then May 20, 1856, only a few days less than four years since Dr. Livingstone started from the Cape. Kilimanjo is in 17° 65' 58" S. lat., 36° 40' E. long. The village stands on a great mud-bank, and is surrounded by extensive swamps and rice-grounds. Dr. Livingstone waited there about six weeks, when he Majesty's brig Frolic arrived off Kilimanjo, and took him on board. There is a dangerous bar at the mouth of the Kilimanjo branch.

Dr. Livingstone left Kilimanjo, July 12, 1856, and arrived at Mauritius, August 12. He returned by the Red Sea and the Suez Canal, and arrived in England on the 12th December, 1856.

The preceding sketch of Dr. Livingstone's arduous journeys is taken from his interesting volume, "Missionary Travels and Researches in South Africa, including a Sketch of Sixteen Years' Residence in the Interior of Africa, and a Journey from the Cape of Good Hope to Loanda on the west coast; thence across the continent down the river Zambesi to the Eastern Ocean," 5vo. 1857.

Dr. Livingstone is at present (Jan. 1858) in London, making arrangements for a new voyage to the Zambesi, in order to form an establishment in a healthy locality, and to enter into friendly commercial relations with the natives. He will be supported by the British government, and is also the recipient of a grant of £1000. A suitable steam- vessel has been prepared for him, and he will be accompanied by three or four scientific gentlemen, who will assist him in his well-intentioned labours.

In 1854, Lieutenent Burton of the army of the East India Company, who had been pursuing the Wandering Africans through his hazardous journeys to Mecca and Medina, performed a short but still more perilous journey to Harar in the Somali peninsula, of which he has given an account in his 'First Footsteps in Eastern Africa.' Though at no great distance from the sea, it gives to this country a comparatively temperate climate. Fortified sufficiently to repel the incursions of the surrounding savage tribes, and under the rule of a young and very arbitrary sovereign, Harar has the rude emporium of a considerable traffic in choice products, more particularly coffee. [Harar, S. 2.] Lieut. Burton has since undertaken a journey from the eastern coast of Africa in the direction of the Lake Nyassa, yet unvisited by Europeans, and may possibly pass through the treasures of the tea and coffee region. This is a question which has excited the curiosity of the learned world from the time of Herodotus to the present day.

AGADEZ, or, as the Tuaregs call it, Ethan, is a town of 15,000 inhabitants, in the province of the Niger, to the north of Hamadah, or high plain, consisting of sandstone. It is the capital of the kingdom of Air or Asien, with which we have recently become acquainted through the travels of Dr. Barth, who visited Agades in 1850. No author is known who has mentioned this place before. Agades is situated on a great plain, once a flourishing town. Agades from its situation, must always have formed an important central place between the Kelowis and the tribes inhabiting the districts to the south and west. There are traditions among the inhabitants of that this town was the capital of the kingdom of Air before the ancient time, from the north, probably belonging to the Berber race. There is, no doubt, a good deal of slave blood among the present inhabitants of Agades, as is the case with the whole population of the south-eastern portion of Air; but there must have been a very ancient stock of indigenous black people, who have transmitted a peculiar language of their own, which is the same language as that spoken by the people of Timbuctu.

Agades formerly contained not less than from 50,000 to 60,000 inhabitants. Dr. Barth was assured by the Turvati, one of whom had been at Timbuctu seven times, that it was much larger than that place. At present the appearance of the town is very different. It has lost almost three fourths of its population. The present number of inhabitants is estimated to be from 7000 to 8000, who are partly merchants and partly artisans. They have a weekly market, and their trade extends as far as from the northern markets of Ouat or Murunk, unless a journey to Mecca.

There exists no intercourse with Timbuctu. The commerce of Agades itself is principally in millet, which constitutes the principal food of the inhabitants. The manufactures are very limited, consisting of leather-work and mats. The saddles made in Agades, particularly those used in riding upon the meheris, or swift camels, and also the sandals, are far famed. Respectless of the degree of civilisation of the inhabitants, it may be mentioned that there are five or six schools in Agades, where the boys are taught to read the Koran, and to write. The women seem to enjoy great freedom. Some of them are pretty, and have Arab features; and among the men Dr. Barth beheld some fine faces. The population is so mixed that it would be difficult to make out the type of the original stock.

The houses are generally spacious, built of clay, and a few are quadrangular. They are all being formed by planks of the doom palm covered with mats, over which earth is thrown. Agades has a tower, which is from 90 to 95 feet high. For such a place, situated in the midst of warlike hordes, a tower is of the greatest importance.
water near the town, and there is also plenty of brushwood.

AGDE. (HERAULT.)

AGNES, ST. [CORNWALL.]

AGRICULTURAL IMPLEMENTS. Few of the productive arts have made so much rapid progress within the last few years than those relating to the cultivation of the soil. In the time of Mr. Fisher Hobbs, we find attentions to this art. A great deal of energy was thrown into those two departments of industry.

As a consequence, greater improvements have been developed in twelve years, than in twice or thrice that space of time under the old order of things.

We have already referred to their report on the Agricultural Implements displayed at the Great Exhibition in Hyde Park in 1851, they grouped them all under certain headings, according to the kind of service they were intended to render in field and farm operations, such as Instruments of Tillage; Implements used in the Cultivation of Crops; Harvesting Implements; Preparations for Market; Machines for Preparing the Food of Stock; and Draining. Such will also be a convenient mode of grouping to adopt here.

Instruments of Tillage.

Ploughs.—Until about the year 1840, four-horse ploughs were still used in many parts of England; notwithstanding that these were the very best ploughs that nature would permit, they were not always in use because of the nature of the land; but they were not suitable for an altered state of agriculture, when the heavy lands were laid down for grazing, and the downs became corn-lands. Even when the swing-plough was invented as an improvement on the old wheel and galloway plough, the weight of draught was little less than before. It was the Messrs. Ramsone of Ipswich who furnished the model on which the manufacturers worked; boards adapted to different sorts. Messrs. Howard and Mr. Besby afterwards paid particular attention to the curvatures of the mould-board; for this is indeed the essential acting part of a plough; raising, turning-out, and throwing over every furrow—a slice of earth in true parallelism with other slices. Foreign agriculturists have often expressed surprise at the length of the mould-boards in modern English ploughs; since it is seen that short boards are better for raising the soil while they turn it over. It has been found, however, by experience, that clay lands require longer mould-boards than those which are drier and lighter; and hence a plough suitable in England might not be so advantageous in foreign countries. Among the ploughs exhibited at Hyde Park, eighty-four were out to trial at Mr. Pusey's estate in Wiltshire, by Mr. Miles, Mr. Shelley, and Mr. Owhaite; while eleven others were tried at Mr. Mechel's farm in Essex, by Baron Menten's D'Osten, Colonel Chalmer, and Mr. Johnson. Of the former group, nine were two-wheel, three three-wheel, and six swing-ploughs. Some were found best at a seven-inch furrow; some broke too much at the furrow of a thatch.

All the swing-ploughs were clearly ascertained to be inferior to those with two wheels. It was further found that a particular curvature of mould-board suitable for a five-inch furrow worked unsatisfactorily in one of seven inches—showing, as many an old farmer would be astonished to hear, that there are no mathematics even in farming. The Royal Agricultural Society had in recent years recommended the use of ploughs for two distinct purposes—the ordinary ploughing, and a deeper ploughing once in four years, when the root-crop recurs, to give the land a more thorough stirring. A common plough fits for this extra work; but all farmers and other makers have constructed powerful ploughs, to be worked at leisure in winter with four or six horses.

Mr. Fisher Hobbs, in reporting on the ploughs exhibited at Cattewater in 1844, considered the first ploughs especially well adapted to the English plough. Elephant ploughs were ranked inferior in power and efficiency to ploughs with iron wheels, made by Ramsone, Howard, and other celebrated manufacturers; these latter, averaging about 90s. in price, were pronounced to be among the best ever produced. A machine for deep ploughing, by Messrs. Rawnsome, of a four-horse plough, was entirely adopted and as well laid as any produced at shallower depths. Some persons have expressed an opinion that the plough has now reached the highest point of perfection; but Mr. Fisher Hobbs, in his treatise on the subject, warns us with praiseworthy caution: "I still look forward to the time when its usefulness will be further adapted to the present operations on the soil, and for leaving the land in a fit state for drills or other machines required to complete its cultivation."

Harrows,—the old-fashioned harrow was always made with square bars and square-set teeth; but as it was difficult to make such a harrow work always in different tracks, even though dragged from the corners, modern makers have constructed harrows which have the teeth set cross-wise, enabling the machine to follow the furrows of the land. The expanding harrow is a very complete implement. The bars at every point of crossing are united by a loose pin, on which they work freely; the width of the harrow can thereby be increased or diminished; the lines, according to the state of the land, can be brought nearer together or spread wider apart; and there are small wheels, easily let down, by which the harrow can readily be moved from one field to another, without disturbing its general mechanism.

Rollers.—It was forty years ago that the late Mr. Philip Pusey, one of the most enlightened encouragers of scientific agriculture, "the landlord was often asked by his tenant for some old tree to convert into a roller; the tree roller, when placed over small cloaks so smoothly as to finish the soil, not to grind them. M. Claus, of Belgium, has invented a roller, intended for narrow round ridges, but also fitted to produce the action just adverted to; it consists of four rings or partial rollers, so adjusted on one axis as to have independent motion, but to form a single roller when drawing the soil have, however, been nearly superseded by the Clod Crushers. This apparatus, invented by Crosskill, is used chiefly for breaking down turnip land which has been fed off by sheep in wet weather and afterwards baked by the sun; it is also a good presser for young wheat in March, when the soil has been swollen, and the roots thrown out by alternated frosts and thaws. The jagged iron teeth form the characteristic feature of this implement. Mr. Gibson has since improved it by putting it round a central axis, containing a series of eccentrics upon an axis, which, in revolving, rub and clean each other.

Scorifiers, Grubbers, and Cultivators.—The implements denoted by these several names are intended to save a great part of the time spent in ploughing on the old method. In one ordinary four-course system of arable culture, the land receives seven or eight ploughings in the four years; but if a scorifier be employed to pare the surface to a depth of two inches immediately after the wheat harvest, much of the four years' labour will be economised. Many forms of these time-saving implements have been invented. Coleman's scorer, with six horses, is adapted for very hard ground. Biddle's, made by Messrs. Ransome, is suitable for going deeper into looser ground. Kirby's and dent's plow plows are midway. They are suitable for ordinary ploughs and scorifiers, and are useful for a very close surface of land. Cotgreave's plow is a cultivator, in which the processes are combined in rather a curious way: while the plow cuts through the turnips, the plowshare cuts up the root and it digs another 5-inch furrow, inverts the soil, and deposits it on the top of the first; and lastly, a sub-pulveriser loosens the soil to a further depth of 3 or 4 inches. Beauchler's potatc plow and subflower may be likened to a common plow with an Archimedes screw attached, which revolves in the bottom of the furrow, thus ploughing and
subsoiling at the same time. Such farmers as have duly provided for some of these various investments, find that they may lessen their ploughings from seven or eight to two or three in the four years. In 1851 Mr. Pusey said:—"I will venture to add, what may appear theoretical, that if ever steam be employed successfully in cultivating fields they may be lessened by half or diggings than with an implement like one of these cultivators; because they are able to work so much wider a space as they pass along in their course. Some of these implements have shares, some points, to dig into and turn up the soil. Several of them have been made to introduce steam-engine cultivators. One, exhibited by Mr. Usher in 1855, consists of a steam-engine moving itself by the revolution of a large circular roller placed under it; and to it are attached numerous small rollers, reversed, rotating, and the engine. Another, brought forward about the same time by Mr. Fiskin, consists of two ordinary ploughs fixed to a carriage or framework of iron, and moved by an endless rope communicating with a steam-engine fixed in one corner of the field. Others have since been brought forward; but this department of the art is confessedly in its infancy.

Implement used in the Cultivation of Crops.

Drills.—The drill has almost driven the hand-sower from English farms. One half of the horse-power formerly expended in harrowing is saved by the adoption of some of the modern drills or sowing-machines; a saving of seed is also effected; and there is also an avoidance of the necessity of digging the furrow and throwing in ridges at a particular angle, which was formerly deemed necessary as a preliminary to hand-sowing. The drill is, in fact, the key to a whole system of husbandry; for, in addition to the advantages just enumerated, the drill is applicable to the use of many artificial manures, distributing them beneath the ground by special coulters, and covering them with earth, that their excessive strength may not injure the seed, which is deposited last of all; while the use of the horse-hoe is almost wholly dependent on the previous use of the drill. The drills of recent invention exhibit much variety and ingenuity of construction. Some are for general purposes, capable of drilling with or without manure, wheat, beans, and turnips, at the different intervals suited to those seeds respectively, from seven inches up to two feet. Some are turnip drills, in which manure, generally ground bones, or superphosphate, is distributed as well as seed. Some, for use in unusually dry weather, pour down each manure-coultler the requisite amount of water mixed with powdered manure. Some, to economise manure, drop the seed and the manure only at those spots in the lines or rows where the plants are intended to stand without molestation from the hoe: each machine having a power of adjustment to different widths or numbers of coulters, which enables it to contribute to the excellence of the modern drills. Messrs. Garrett have improved the wheeling or moving power of the general-purpose drill, to the ease of the horse and the driver; the turnip drills have greatly improved; and they have constructed a hand-harrow drill for distributing grass-seed broadcast in a very effective manner. Messrs. Horsey have constructed a drill for depositing manure-dust and turnip-seed on ridges, and reducing the ridge by concave rollers to a compact rounded form; they have also introduced india-rubber tubes for conducting the seed down to the channel made by the coultier, instead of using a series of tin cups; and they have also done much to enable the drill to deposit seed and manure on hill-sides, and to work equally well on ridges and on the flat. Messrs. Goss have introduced the self-adjusting steergage corn-drill, adapted for being driven with great nicety, and for delivering the seed equally well going up or down hill. One of the drills lately invented is especially contrived for distributing equally well liquid manure or the thickest sewage. In short, the drill is now an implement to which all the farmers devote very sedulous attention.

Top-Dressers or Manure-Distributors.—Although wheat is sown with the manure-drill, being invariably composted with its requisite nitrogen by farm-yard dung or by sheep-folding, yet it generally requires a top-dressing of manure during its growth. This use to be applied by hand has been greatly increased, both of which one is by Mr. Holme; he has been invited to perform the operation in various districts. It distributes three or four bushels per acre of guano or nitrate of soda, or a larger proportion of rape-cake or superphosphate, on wheat in the spring of the year. The method is as simple thus: the ridged rooting of modern horse-hoes of Messrs. Garrett and other makers has at one time four rows of turnips, six of beans, or nine of wheat. The modern machine does the work at half the expense of the hand-hoe, and much more completely. A modern rigid coal-boundage for the purpose of gathering the folk farms; by its revolving principle the plants and soil attached are thrown up together, but the soil by its greater weight reaches the ground before the plant, which, lying bare with its roots exposed on the surface, soon withers away.

Harvesting Instruments.

Reaping-Machines.—No other implements applied to agriculture have attracted so much attention within the last few years as reaping-machines; partly for the singular ingenuity displayed in their construction, and partly owing to the emulation between European and American inventors. At the opening of the present century it was thought that a successful reaping-machine had been constructed; but Parliament loi the labour of the unskilled laborer it was so intricate as speedily to fall into disuse. Another was invented many years afterwards, which cut off the heads of the corn, but left the straw standing—a fatal defect. When machines had been invented for reaping, it was found that the modern machine of Messrs. Garrett could reaping-machine at once rivetted attention; Mr. Hussey competed with him by means of another invention; and the different implement-makers, entering into manufacturing arrangements with these and other inventors, speedily increased the number of reaping-machines. The most modern part of each machine is a horizontal saw or serrated knife, which by a rapid reciprocating motion cuts the straws very near the ground; while there are peculiar adjuncts for laying down or depositing the straws with their ears of corn regularly after being cut. This display of Hussey's and McCormick's machines in Hyde Park led to a curious revelation. The world then learned, almost for the first time, that England, or rather Scotland, had long possessed a reaping-machine of somewhat analogous character, although not in use. The facts brought to light were in brief as follows: In 1827 the Rev. Patrick Bell, son of a tenant farmer on Lord Panmure's estate in Scotland, became impressed with the disadvantages under which the farmers lay through a critical period of the year, and he constructed a rude machine intended to do much more in a given time than a sickle would perform. The machine acted on the principle of the sea scythe. Mr. Bell, from a model, constructed a wooden model with his own hands, and then had the iron-work fashioned from it by a village blacksmith. He first tried his invention in cutting some oat straw stuck up by himself on end in a layer of mould in his father's shed, and then observing certain deficiencies, he made an attached piece of apparatus to deliver the corn in regular swathes; and another for collecting and pressing the corn against the cutter. The invention soon became known to the neighbourhood; others were made on the same model; and the Highland Society's premium that was year given to Mr. Bell; but, probably from defects in the construction, the machine did not work satisfactorily to the farmers, and they declined to use it. To an offer made by Lord Panmure, to give the inventor the use of his patent, Mr. Bell replied that he had no wish to make a profit out of any agricultural invention. For twenty-four years the subject was allowed to stagnate; insomuch that when men were told of the humble Scottish minister's reaping-machine at the Royal Agricultural Society. At the Carlisle meeting, for instance, in 1856, there was one of Bell's original construction improved
Another is, that if a farm be of small or moderate size, it will not support the expense of a fixed steam-engine; whereas a portable engine may be available for two or three farms, at a fair ratio of expense for each. A third is, that whereas threshing can only be done under cover in barns by fixed engines, it is perfectly feasible in the open air by a locomotive engine—a plan, healthier and more expeditious for the labourer, and rendering probable a greater consumption of farm produce, requiring to be constructed by the landlord.

The Royal Agricultural Society gave the first impetus to the construction of moveable steam-engines for farm purposes; and the annual prices and exhibitions have been very influential in determining farmers to make improvements, to the great benefit of agriculture. In the collection of 1851, there were engines of this kind exhibited, made by Horsey, Tuxford, Clayton, Barrett, Hensman, Bullin, Roe, Ransome, Garrett, and other makers. Every one felt that the invention was still in its infancy; for the worst specimen exhibited consumed three times more coal than the best. Of thirteen specimens examined, the nominal horsepower varied from 4 to 9; the time of getting up steam, 28 to 83 minutes; the coal used in getting up steam, 0.1 lb. to 75 lb.; the coal consumed per horse-power per hour, 0.79 lb. to 25.80 lb. Mr. Locke, the eminent engine inspector, in reporting on these trials, said, "If I might be permitted to suggest a little advice to the makers of these engines, I would beg of them to attend more to the proportions of the boiler and the engine, more to the condenser, and less to the size of the cylinders. It is a want of good proportion in several of the engines; and this to a mechanic or an economical farmer, is of more importance than a profusion of brass."

At the Carlisle Agricultural Meeting in 1855, a manifest improvement upon the first abolition machine was made. The maximum consumption of coal per horse-power per hour was 10 lb.; while the minimum (in Tuxford's engine) was only 3.7 lb. It was, however, considered by some of the farmers that this was somewhat too exclusively attended to. "The conditions of competition laid down by the Society for portable engines have unfortunately led to the production of engines only intended for winning the Society's prizes, and known as 'racing engines,' requiring the nicest care; instead of those simple and effective engines which may be safely entrusted to the management of intelligent farm-servants;" and it was recommended in future "to submit the prize engines to subsequent trials, for a lengthened period, under the ordinary management of a farm establishment." At the Salisbury Agricultural Meeting in 1857, there were no fewer than twenty exhibitors of agricultural steam-engines; of which one firm, that of Messrs. Clayton & Shuttleworth, made at the rate of 500 engines per annum. Some of the makers had completely abandoned the idea of portable engines, and were concentrating on making the bath machinery, cutting chaff or roots, grinding corn, pulping mangold-wurzel, splitting beans, sawing wood, pumping water, and lending their boiler for steaming potatoes or roots.

**Threshing-Machines.**—Threshing-machines worked by horses were considered, in their day, a vast improvement over the flail of earlier times; and so they unquestionably were. It occurred to Mr. A.m, the agricultural engineer, however, that a large amount of power was wasted in dragging dead weight; and he found on experiment in 1849, much to the astonishment of farmers, that in a four-horse machine the strength of which was equal to 2,000 lb. of good iron work itself, while only one horse-power was available in threshing the corn. The makers immediately began to reform their methods of construction; and they gradually succeeded in bringing down the friction and dead weight to two and a-half, two, one and a-half, and eventually, one horsepower in each of four. At that point, however, the higher class of farmers began to think more of steam-threshing than horse-threshing. In the one case, as in the other, the threshing arms or levers begin their work as soon as a central axis or shaft is set in motion; but in the other, the levers work as in a horizontal plane by the aid of machinery. Several threshing-machines were tested by the Exhibition Jury in 1851; they differed greatly in excellence; but on an average they required fifteen-horse power to thresh two and a-half, two, one and a-half, and oneshared hares per hour, 10 horse-power per minute for barley. It was found, however, that those which worked with least horse-power were not necessarily the best in the quality of work done, as denoted by the three tests of excellence—clean threshing, unbroken...
grain, and unimpaired straw. Maltsters continued up to that year to distrust machine-threshed malting barley, on the ground that the grain was often too much bruised and injured for germinating. The makers had therefore every reason to try and improve these threshers. It was calculated that wheat is usually threshed for about 3s. 5d. per quarter, all expenses included, at a resulting cost less than 1s.; and it is therefore if quality were good, that very much of the quantity supplied would unquestionable be of the year 1855 the improvement in the machines was most decided. There were several exhibited in that year at Carlisle, of about eight-horse power each, but the best estimated in twenty minutes. The judges, in reporting on the trials, said, "These machines are now become of material importance, inasmuch as they enable the farmer in so short a time to prepare the corn for market. They have, in fact, almost entirely superseded carting; and without their powerful aid the full supplies of corn could not this autumn have been furnished for consumption. The extraordinary demand for the threshing machine, and its daily use on the farms, are circumstances that prove its estimation by the agricultural community." A fixed steam-engine, working systematical barn-machinery, threshes corn more economically and effectively than portable machines; but the latter are of great importance for as far as they can be let out by their owners to different farmers, always to be on call according to exigencies of the harvest. No kind of agricultural machinery has met with more opposition from hand-labourers than threshing-machines; but the prejudice in favour of the old and in the main is dying out in this as in other directions. It has been recently the case, however, that not without a lesson from Salisbury in 1830 for firing barns containing machinery; whereas in the same town in 1857 the labourers cheered loudly on witnessing the success of the reaping machine."

Threshing-Machines—It may have been corn to the wind, as in the old process, it is now winnowed by every ingenious and intricate machinery. Malters Hornby were among the first to achieve success in the construction of such machines. Their winnowing apparatus is fitted with a spaded roller, working through a graining frame of the sort of hopper; it separates the corn from the trash in the rough pulpy state, as it comes from the threshing machine, without being previously riddled; and it can be adjusted to suit corn either in rough chalk or in any other state. The meshes of the grating are so varied, and placed in such relative positions, that the winnowing-machine will separate the whole produce of the threshing-machine into "best corn," "good tailings," "tailings," "whites," "screenings," and "chaff," at the rate of fifteen quarters an hour, and a grating over for separating the trash, at the rate of twenty quarters per hour. Not only has the skill been nearly superseded by the threshing machine, and horse-power by steam-power, but the threshing-machine itself has improved. Where before the corn was brought out in a rough way, as it was in 1847, has now been brought to a perfect state to combine the threshing and winnowing machines in one, beating the grain from the ears, and then cleaning and separating it ready for market.

Machines for Preparing the Food of Stock.

Turnip-Cutters.—Formerly farming stock was fed with hay, or turned out to pick over straw, occasionally mixed with turnips; but scientific and practical men aided each other by degrees in discovering that this labour of the jays wasted the muscle of the animals, and retarded their progress. Hence the invention of many ingenious machines for facilitating the preparation of food for live stock. One of these is the turnip-cutter for cutting the turnip. It is an important part of the rural life on farms of any extent; and the cost of making and using a good turnip-cutter is a return on the land by which the agriculture of the country is burned in, where it is dried, and is finally cut and threshed. The fuel in making one of these machines is oil, which is burnt in a stove; this has two advantages; it may be seen that the machine is by far more economical in the use of fuel than any of the old-fashioned machines. This is an important advantage of the new machines, which are capable of covering an acre in a day. The turnip-cutter is operated by one horse, and is made to cut the turnips into turnip-cucts, which are then utilized as a food for live stock. These machines are made in various sizes, from small ones for use in private farms to large ones for use in large estates. The cost of a large turnip-cutter is about £50, and it can be operated by one man. The advantage of this machine over the old-fashioned one is that it can be used in all kinds of weather, and is capable of doing the work of a dozen men in a day.

Chaff-Cutters.—The cutting of straw into very small pieces, to supply the deficiency in natural chaff for cattle-food, is at first done by hand, with a sort of knife hinged at one end; then by a series of knives working round an axis, and driven by a horse,中国古代的合作社在丰收季节用这种机器来制作草料。"The spectators," said Mr. Pusey, on whose estate the machine was tried, "are surprised to see two
The machine is worked by two horses; the man is firmly and easily fixed into the ground, affords a three or a four-horse team from a great height, working at an easy speed. The chief defect in the earlier specimens was an inequality in the level of the channel excavated by the plough, because the upper and lower parts being fixed at an equal distance apart, any unevenness of the surface was hidden by the unloading drum below. This defect was partially remedied afterwards; but the difficulty of ensuring horizontality in the drain has continued to be an obstacle to the use of this machine. The cost being considerable, but a large landowner would find profit in buying such a draining plough; but the machine can easily be let out for a month, or other definite period.

The aggregate result of all these various improvements in the construction and application of agricultural implements is overwhelming. Mr. Pease, in reporting on this subject, as Chairman of the Exhibition Jury, in 1861, stated the estimate was: By using lighter ploughs, cultivators that lessen the necessity for ploughing, drills that economise both seed and saving-power, horse-hoes instead of hand-hoes, varied nature of manure, and other advantages, to the done right pumping-plant, fixed and portable steam-engines, steam-threshing and winnowing machines, turnip and cut off cutters, drainage-pipes and drainage-plants having been affected in £20,000 of one-half the former outlay in cultivating a definite amount of corn.

It had been rendered further demonstrable that machinery which had been comparatively uncertain in culture, by enabling many of the operations, in double, in or under arrangement, to be done right by machinery, which could hardly have been done at all by the hand method.

Mr. Evelyn Denison (afterwards Speaker of the House of Commons) prepared a Report on the Agricultural Implements displayed at the Paris Exhibition De L'Industrie, in 1855, in which he endeavoured to estimate the material advantage accruing from the use of machinery in agriculture. Mr. Sidney, at the close of 1857, gave a few figures intended to prove that, in the course of twelve months, great quantities of land had been concentrated on and saved in the cultivation of corn. The estimate was that within six years—that is, since Mr. Pease prepared the Great Exhibition report—the landowners of the United Kingdom had expended ten millions sterling in draining two million acres of land, on principles which, at the time, were supposed to be sound. Every acre that was saved in the items already enumerated, there is that precious, though not easily calculated advantage resulting from the economy of time, by employing machinery at full force during short intervals of fine weather. (Report of the Great Exhibition, 1851.)

All this is more than can scarcely be said to exist yet in England. Notwithstanding the acknowledged importance of exact information as to the amount of our agricultural production and consumption, especially in corn, and the interest that is taken in the subject as shown by the attention given to it with, in London, in connection with, in London, the question of the corn laws, there is a little better than ingenious guesses, no steps have yet been taken to secure a correct estimate of the expected amount of the coming crops, and the state of live stock. Such estimates as are made are, of course, of little value; and something which nothing can be more fallacious. The great differences in cost, cultivation, and even of climate in England, make the application of the doctrine of average almost more indisputable in agriculture than in any other trade. It is by the occurrence of exceptional results in one trade being looked upon as a law in another agriculture as in everything else, and the more any subject has the appearance of chance, the more necessary it is that the experiences should be registered, in order to arrive at the law expressed by an average. The inconvenience and loss occasioned by the absence of statistical returns has been often felt. After the harvest of 1846, the average price of corn for six weeks, from the middle of August to the end of September, was 35s. 6d.; the lowest price being 20s. 6d. In October, the price improved; but in November it again fell to 50s. But as soon as the new year had begun, symptoms of scarcity, manifested themselves, and the wheat of that same harvest, notwithstanding its large quantities, reached the price of 102s. 6d. per quarter. In this case, a knowledge of the produce of the harvest would have saved the farmer from the sacrifice of his property at the beginning; it would have saved the country from the vast sums of money spent on the purchase of corn, occasioned by a sudden rush into the market for large supplies; it would have probably saved considerable waste of food during the period when it was improperly cheap; it would have saved inconvenience to the foreigners in whose markets our purchases inevitably increased the price of wheat; and the gains of the merely speculative corn-dealers would have been saved to the community.

The desirability of some knowledge on so important a subject has led many individuals to form, from the best available sources, general estimates, but the discrepancies show the unreliability of such estimates for any practical purposes. Some endeavoured to arrive at it by taking the acreage of the kingdom, the proportion supposed to be cultivated, and the amount of corn grown, as estimated by Mr. Gregory King, who wrote in 1665, was among the earliest. He estimated England and Wales to contain 36,000,000 acres of which he supposed half to be uncultivated. Davenport, Gove, Tappin, and others, arrive at results, which, as far as they can be made to agree, estimates varying from 31,048,000 acres, to 46,916,000 acres, which was the estimate of Arthur Young, and was adopted by Mr. Pitt in his calculations for the probable amount of the income of the kingdom. This estimate was stated at 37,324,916 acres, which was very near the estimate of Dr. Becke, who gave it as 38,498,579. Others, again, have endeavoured to ascertain the consumption by multiplying that of each individual by the number of the population, but here they differ materially, varying from 6 bushels to 8 bushels for each individual, an unsatisfactory difference of one third. We will now enquire what measures have been taken in providing statistics by the government.

What are called the corn averages, of one or more tables originally intended to regulate the duty on corn; but if modified and improved, they might be made an auxiliary to agricultural statistics. For a century previous to the year 1851, such returns were collected from the principal seaports and boroughs—stating the average price of corn at the time of the imposition of duty on foreign corn; the collector of the returns was appointed by the magistrates of the town or borough in which the return was made, but the salary was paid by the government. In 1821 a change was made. The returns were collected, not by the local authorities, but by the towns in England and Wales. Every corn-merchant, miller, baker, and malster, was ordered to make weekly returns to the inspector. The inspector provided a place for the reception of those returns; he posted up in some convenient locality the gross weekly returns, with the average price of each description of grain sold in the preceding seven days. These averages were then forwarded to the Comptroller of Corn Returns, in London, who added up all the gross averages from the various places, and obtained the total average for the whole kingdom—which average regulated the duties on the admission of foreign corn for home consumption. When the 'sliding-scale' came into operation, there were several instances of the averages being tampered with, in London, to the advantage of the corn merchants; for this was done by fraudulent persons, with a view of lowering the rate of duties by fictitious sales of large quantities of corn; thus swelling the quantity returned, raising the price of corn, and lowering the cost of living. Whether wise or not, led to the appointment of excisemen, without any increase of salary, in place of inspectors, as the latter might die off, for taking the corn averages; and the returns are believed to have suffered in accuracy from this change. When the sliding-scale was stopped, 85,279 acres were made; the corn averages ceased to be as valuable as before in respect to fiscal regulations; but they remained important in connexion with the commutation of tithes; and it is now considered that they might render useful service to the community.
the agricultural statist. The list of towns whence the returns are made has been largely increased; in all the towns thus added, excisemen have been appointed instead of inspectors.

In these returns, it is evident, nothing beyond the average prices. In 1832 the attention of the government was directed to the attainment of more satisfactory results. In the previous year, a statistical inquiry had been made by a committee of the magistracy of Norfolk, respecting the agricultural statistics of that county. The committee distributed circulars to 650 parishes; but 354 of these declined to answer the questions submitted to them, and the committee had no other resource than to infer from the 496 affirmative to the latter, that the result was useful as a beginning; and in 1832, when the Statistical Department of the Board of Trade was established, Lord Auckland saw the importance and necessity of obtaining correct agricultural statistics. Nothing was effected, however, until 1836, when the Board of Trade resolved to make a small experiment of its own. Circulars were sent to the clergymen of 156 parishes in Bedfordshire, enclosing schedules of the returns required, and asking for co-operation. This experiment yielded a signal failure; for out of 156 parishes to which the circulars were applied, only 27 returns were answered. It was a time when the clergy and the high Tory party distrusted the suspected radicalism of most new Government projects, and it was on that account an unfortunate period in which to make such experiments. Still, though the result was a failure at that time, in 1837 Mr. Gladstone, at that time President of the Board of Trade, stated in the House of Commons that the subject was under his consideration. The Board of Trade, the Home Office, and the Poor Law Board, next had a long correspondence in which evidence was taken of the practical difficulties with which they three might undertake the management of a system of national agricultural statistics; and it appears to have been decided that, as constituted at the time, the Poor Law Board could not adequately fulfill this duty, and that the Board of Trade resolved to make another attempt, or rather three small attempts in the three kingdoms—North Hants in England, Mid-Lothian in Scotland, and Ballyborough Union in Ireland. The Irish inquiry was made by a private individual, and was satisfactory; the Scotch inquiry was managed by the schoolmasters of the respective parishes, and was equally successful; but the English inquiry was an utter and disheartening failure. The Board of Trade, in this last-mentioned case, addressed communications to the Board of Guardians of the different unions; while the Poor Law Commissioners backed the application, by requesting the Board to employ their own paid officers to induce the occupiers of land to fill up the schedules that were sent to them. This was almost a waste of time; for only any returns were obtained; and a strong impression was left that nothing less than compulsory powers would be available for obtaining the desired statistics.

The next attempt was made in 1847, when Mr. Miller Gibson, then the head of the Board of Trade, brought into Parliament its 1847 Bill to provide for the Collection of Agricultural Statistics in England and Wales. By the provisions of that Bill, the duty of obtaining the statistical information was to devolve upon the Registrar-General of Births, Deaths, and Marriages; the superintendent registrars throughout the kingdom were to be charged with the appointment of agricultural enumerators; and the enumerators were to prepare lists of all the occupiers of land, including those having three or more acres, and blank forms to those occupiers, and to collect those blank forms after a interval of fourteen days filled up with the several entries of particulars. This being done, the enumerators were to classify the returns, and construct general tables from them. These tables were to be transmitted to the superintendent registrars, by them to the Registrar-General, and by him to the Board of Trade. These returns and tables were to apply to the month of June in each year, and the first time in the public, was not yet learned to feel much interest in the subject, and as various party questions were then on the table, the bill shared the fate of many others, and fell to the ground.

In 1854, an attempt was made to obtain complete statistics of the returns of the corn exported. The selection was unfortunate, for the impression was instantly received that the returns would lead to additional assessment, and no explanation availed to remove that belief. In addition it was generally feared that such returns would be used against the farmers by their landlords in order to raise their rents, they, in very few cases, holding their farms upon lease. The West Riding of Yorkshire was the only division from which a complete return was procured. In its case, however, the returns were found to be useless. Many Unions refused altogether, alleging that their officers had sufficient other duties to perform, and it was suggested that these complaints were the result of the continued opposition that would be offered to the investigation of a farmer's affairs by Poor Law officials, the most of them represented that all that was required was a compulsory act; and accordingly the Lords' Committee embodied a series of resolutions in their report, recommending the government to introduce a bill into parliament for two returns a year, in July and November, to be carried out by the same machinery. The government however have not yet adopted the recommenda-
the assistance of farmers; he succeeded in removing their objections, and convincing them of the advantages; and by means of local branches of the parent institution succeeded in procuring complete returns for the kingdom. These returns are continued annually, and though there have been a few omissions, are the most complete in their details of any yet known.

Though the absence of similar returns of Scotland deprives them of much of their value, they are still, conjoined with those of Ireland, of great importance. We give an abstract of the returns for 1856 and 1857. We may premise that the returns are from holders paying a yearly rent of 10l. and upwards (exclusive of tenants of woods, villas, feuars, householders and the like) in all the counties of Scotland except Ayrshire, Inverness-shire, and Partick; and the counties of Strathclyde, of which the Ivean part of Bute which lies in Arran, in both years, and in Caithness, Sutherland, and Orkney, in 1856, where the returns are only from holders paying a rent of 20l. and upwards. Woods, sheep-walks, houses, roads, and waste, are omitted in the calculation.

In 1856 the number of occupants was 42,919; in 1857 there were 43,492. The number of acres under rotation of crop was 3,045,191 in 1856; of which, of wheat there were 226,526, of barley 176,204, of oats 915,816, of rye 4029, of bere 15,368, of beans 40,740, of peas 4617, of vetches 18,231, of turnips 460,131, of potatoes 149,331, of mangold 3531, of carrots 1523, of cabbages 1485, of rape 1407, of oil-seed 3732, of turnip-silage 1709, other crops 14,464, and grass hay and hay rotation 475,776, which leaves 1013 of the stated total unaccounted for.

The produce was 7,370,352 bushels of wheat, 5,851,970 of barley, 31,966,361 of oats, 6,540,267 tons of turnips, and 413,800 tons of oats and turnips, in 1856. In 1857 the total number of horses under crop was 5,566,672, of which there were wheat 228,125, of barley 196,387, of oats 938,013, of rye 9988, of bere 21,007, of beans 39,196, of peas 8675, of vetches 18,418, of turnips 476,591, of potatoes 139,819, of mangold 1104, of carrots 1761, of cabbages 184, of rape 152, and of oil-seed 304, of turnip-silage 2576, of other crops 577, of bare fallow 10,582, and of grass and hay in rotation 1,469,080, an excess of 989 acres over the stated total. The produce was 8,231,864, 6,494,456, 3,306,963, 16,142,180, 18,166,434, 4,009,790, 6,690,109 tons of turnips, and 430,460 tons of potatoes. In 1856 the total number of horses was 177,953, of milk cows 209,900, of other cattle 473,384, of calves 197,709, of sheep and lambs 616,500, of swine 125,984. In 1857 the numbers were, of horses 185,469, of milk cows 303,918, of calves 195,196, of sheep and lambs 5,683,185, and of swine 140,354. In this account the horses, cows and swine kept in towns are not included; and it is estimated that above 300,000 head of stock, and about 50,000 acres of landage are held by occupiers not in these returns. Fife and Haddington show the greatest proportional acreage in wheat and in white crops generally, and Aberdeen and Argyle the greatest in turnips; those counties also possessing the greatest number of live stock.

In Ireland, where the interest felt might have been supposed to be less, statistical returns have been obtained in an excellent form, and with no opposition. The task of gathering the returns was confided to the constabulary in 1853, and they have been continued annually since. We append the return of 1857:—In that year the returns show that there were 5,860,069 acres under crop, being an increase of 106,642 acres over the quantity in 1856. Of these 662,881 acres were in oats, 1,077,753 in peas, 424,725 in beans, peas, &c., showing a small increase of cereal crops generally, but a decrease on oats of 56,559 acres. On green crops there was a general increase of 45,637 acres, potatoes occupying 1,145,950 acres, an increase of 42,216 acres, and flax had decreased from 106,311 acres in 1856 to 98,074 acres in 1857; and turnips had decreased 4,487 acres. Meadow and clover had increased from 1,203,787 acres to 1,369,421 acres. The produce of the 6,753,681 acres in cultivation in 1856, had been 2,756,183 of wheat and of which 14,775,041 barley of oats of 14 stone each; 1,367,452 barrels of barley of 16 stone each; 50,709 barrels of beer of 16 stone; 72,165 barrels of rye of 20 stone; 431,661 bushels of beans and peas; 35,206,346 barrels of turnips, and 7,970 tons of turnips; 2,654,322 tons of manure; 333,650 tons of cabbages; 3,006,533 stones (14 lbs.) of flax; and 3,492,723 tons of hay. The total number of holders of land was 592,498; of whom 36,474 held not more than one acre; 82,095 not more than five acres; 179,334 not more than fifteen acres; 159,454 not more than
thirty; 71,156 not more than fifty; 53,279 not more than one hundred; 21,292 not more than two hundred; 8943 not more than five hundred; and only 1655 held upwards of five hundred.

Live stock, except sheep, had increased remarkably. The number of horses was 600,693, an increase of 27,385; the number of cattle, 3,618,544, an increase of 30,686; the number of sheep, 3,468,676, a decrease of 245,618. Pigs numbered 1,283,532, an increase of 333,637.

Road contractors in Ulster are required to keep the roadsides and fences free from weeds, and surveyors in the other provinces are recommended to obtain authority from grand juries, &c., to enforce in them similar regulations.

The above are some of the causes which have formed the basis of having statistical returns of their agricultural produce. Austria, Prussia, France, Denmark, Hungary, Belgium, and the United States of America, have all such returns more or less perfect, among which those of Belgium take a high rank, and are nearly equal to those of Scotland. Such statistics for the whole of a kingdom are highly valuable for the regulation of the inhabitants of that kingdom; but if we possessed them for the whole of the civilized world, what are called the chances of agriculture would probably be reduced to a certainty, and the price of food would remain with little or no variation.

AGRODROMA. [ALLAUNE, S. 2.]
AGROSTEMMA (from ἀγρός, a field, and στέμμα, a crown), a genus of the order Compositae. Of the three species of this genus, one is Agrostemma cocconeum, in ordinary culture.

AIGUESMORTES. [GARD.]
AIGUILLON. [LOT-ET-GARDONNE.]
AKIN, ARTHUR, the eldest son of John Akin, M.D., was born in 1784. Arthur Akin began his literary career, we believe, as editor of "The Annual Review," upon the title-page of the first six volumes of which—1803-1808—his name appears as editor. His earliest scientific work was "The Manual of Mineralogy," of which the first edition was published in 1814. Besides this he was the author of a "Tour in North Wales," a "Dictionary of Chemistry and Mineralogy," and a "Dictionary of Arts and Manufactures;" and also of numerous papers in various scientific journals. For a long series of years Mr. Akin was the resident secretary of the Society of Arts, and a frequent contributor to its "Transactions."

Ain was also one of the oldest fellows of the Linnæan and Geological societies. Mr. Akin was a map of quiet retiring habits, and outlived his scientific reputation; but was well known in scientific circles as one of the most regular attenders of the meetings of the learned societies in the metropolis, and was generally esteemed. He died at his house in Bloomsbury, London, April 15, 1854, in his 81st year.

AIRA, a genus of Grasses belonging to the tribe Stenarias, and distinguished by possessing a lax panicle, two-flowered glumes, the outer pale terete on the back, and a dorsal awn. There are several species, but that which is best known is A. cepaeus, the Tufted Hair-Grass. It has long and flat leaves, with a fibrous perennial root. It flowers in the beginning of August, and reaches a height of four feet. It grows naturally on marshy damp soils, in the form of large tufts. It is a wiry harsh grass, and is rejected by domestic animals. It may, however, be advantageously sown as a cover crop, on the banks of rivers and of canals, in parks, and other open places.

AILBE, RIVER. [YORKSHIRE.]
AITIONA (after Mr. W. Aiton, for many years head-gardener at Kew) a genus of plants belonging to the order Meliaceae. The A. Capensis is a native of the Cape of Good Hope, and is cultivated in our greenhouses.

AKHALZIKH, a town in Russian Armenia, situated near the watershed between the Black Sea and the Caspian, on a fertile plain, and on the south-east from the Perengah Dagh, in 41° 40' N. lat., 43° 10' E. long. Population about 15,000, who are chiefly Armenians. It was formerly the chief town of a pashalik in Turkish Georgia; and is now the capital of the province of Akhalzikh. [GRASZIA.] The town is fortified, and of considerable extent. The most remarkable building after the citadel is the mosque of Ahmed, which is built on the model of that of Santa Sofia at Constantinople. Connected with the mosque is a college, and a library rich in Oriental literature; but it is said that the best works it contained have been carried away to the royal library of St. Petersburg. The Armenians have several large churches, and there is a mosque and a synagogue. The trade is in silk, tea, and money; there is some transit trade, as the town lies on the road between the port of Batoum and Tiflis, being 80 miles E. from the former and 105 miles W. from the latter.

AGOAS, a province of Brazil, which, up to about 1840, was a district, or comarca, of the province of Pernambuco; but, on account of its increasing population and wealth, was formed into a separate province, which is under the administration of its own governor. It is situated between 9° and 14° lat., 36° and 39° 30' long. It borders on the south of the province of Sergipe del Rey, from which it is separated by the Rio de San Francisco, along the northern banks of which it extends to the great cataract, called Cachoeira de Paulo Affonso. On the west and north it is surrounded by the province of Pernambuco, from which it is separated for a considerable space by the Rio Unna. The Atlantic washes its eastern side. In length, from east to west, it extends about 150 miles; its average width probably does not exceed 60 miles. The area is about 900 square miles.

Two-thirds of this surface are covered with mountains. They form the southern declivity of the elevated and hilly table-land, which occupies nearly the whole of the country, and extends to the eastern coast. These mountains come close up to the river San Francisco as far east as the mouth of the Rio Sacaro, and terminate in Alagosa, at a distance of about 30 miles, or little more, from the sea. This region is almost entirely covered with wood, and contains a vast wealth of timber, which affords a considerable article of exportation. The valleys and more gentle slopes of the mountains exhibit a considerable degree of fertility. Along the eastern base of the mountains extends an undulating country, the climate of which is so equable as to afford about half the country between the declivity and the sea. It is likewise wooded, and has a light soil, very fit for the culture of cotton, which is rapidly extending. The country along the sea-shore, and at a distance of about 10 miles somewhat less from it, is low, level, and covered with a thick alluvium, which has been brought down by the numerous small rivers that rise on the eastern declivity of the mountain region, and deposited along the edge of the undulating tract. This soil is of the best quality for the cultivation of every kind of intertropical productions. A considerable portion, however, of this tract is still covered with swamps, and the tide, which rises along the coast from 4 to 5 feet, enters the mouths of the rivers, and has changed the adjacent country into a marsh. The large lagoons of the coast, one of which is called Lagoa do Norte, and the southern Lagoa do Sul. Its water is salt. Only canoes can navigate the river Alagosa, which carries its water to the sea. The rich plantations situated around the Lagoa do Sul carry produce to the northern lake and the town of Alagosa, whence it is transported to the harbours of Taragua and Pajassara. Farther south is the Lagoa do Sitiquia, which is 15 miles long from north to south, with an average width of 3 miles. A river of the same name runs southwards to the sea.

The coast along this section is in general low, with a few small hills along it, and with only a few small capes. The major part of the coast of this province is opposite to the province of Sergipe. Currupipe, which is farther south, is a harbour of moderate size, formed by a reef extending to a distance of 300 yards from the shore, which breaks the fury of the sea. The harbour may be entered by two channels in the reef, but the sea is not generally good. The river which flows into this channel bears the same name, and is navigable for canoes for several miles, but has very little water on the bar at its mouth.

The only river which here deserves to be noticed is the
San Francisco, which enters Alagoas at its western extremity at the great cataract of Paulo Affonso, where it is said to descend 50 feet in perpendicular height. It then runs for some 80 miles to the Alves do Caninde, forming several mists and smaller cataracts, between rocky banks several hundred feet high, and extremely rugged. Many rocks occur in the bed of the river, and it is not navigable. At Caninde the width of the river increases to half a mile and more, and it is impossible to navigate it. The mouth of the river is formed by the confluence of several brooks, which are of moderate height as far down as Caninde. Below Penido the river enters the alluvial tract, in which it divides into several branches, forming a great number of islands, generally low and abundance which, when united, form a barrier which is washed by rice, maize, mandiocé, sugar, and vegetables are raised in abundance. In the rainy season they are overflowed. The branches of the river unite again, and it disentangles by two mouths of different size. The latter is the larger, being nearly 8 miles wide, but has so little depth that smacks can enter it only at high-water, and must there wait for the full tide to go out. They sail as far up as Penido, 25 miles from the mouth. Father up the navigation is solely by ajacis, that is, two or more canoes moored together with cross-pieces of timber below. In ascending the river sails are always used, as the wind from eight o'clock till the following morning's dawn blows always from the east. The ajacis always descend the current, which is swift, though not very rapid.

The climate is hot and humid. The heat in the rainy season is frequently oppressive, except along the coast, where it is moderated by sea breezes. It is less hot in the dry season, and also more healthy. The wet season occurs from November to March, and the rains are very abundant, but showers are not rare in the dry season also.

Tobacco was once the staple article of this province, and was especially sent to the western coast of Africa; but since the abolition of the slave-trade this branch of agriculture has completely been deserted, and has been replaced by sugarcane and cotton, which at present constitute the staple articles, the first being raised in the alluvial and the second in the undulating tracts. As food are raised—mandiocé, maize, rice, plantains, yams, and fruit-trees, so as to supply the wants of the inhabitants. The most common fruit-trees are oranges, pine-apples, jack-trees, cocoa-nuts, and palms. The mamona-tree is carefully cultivated in some districts on account of its oil, which affords a great article of export. Alagoas has extensive forests of rubber-trees, even in its lower districts, and affords the best rubber in Brazil. It is exported to Bahia and Recife; and many small vessels are built in the province. Some of these vessels are very durable, especially those named Sueciras, Pe Reos, Vintamico, and Tataba, but their wood affects the iron."}

**ALAGOAS**

Alagoas, the capital of the province of Alagoas, in Brazil, is situated in 9° 40' 8" S. lat. 30° 60' W. long. It is built on the western margin of the lake of Manguaba, by means of which, and on the other side, the inhabitants of the rich country surrounding the lake to the harbour of Taraga. This produce consists chiefly of sugar and tobacco. The town has a population of 12,000, and contains several convents and a grammar-school. The country about it abounds in fruits, especially orange-trees and jack-trees.

Henderson's *History of Brazil*

**ALAININE.** (Chemistry, S. 1.)

**ALAUDA.** (Alaudinae, S. 2.)

**ALAUDÆ.** The name of this order is derived from birds belonging to the order Passerina, and the family Corvidæs, is thus characterised by Mr. Swainson:—

Bill more lengthened than in any of the Fringilleæ; the tip entire or only slightly notched; the cilia slanting, the bill much lengthened, pointed, and generally as long as the quills. Claws very slightly curved; the claw of the outer toe always shorter than that of the inner toe; the hinder claw considerably lengthened, and either nearly straight or very slightly curved.

**Alauda.** (Linn.)

Bill cylindrical; nostrils concealed. Wings very long; no spurious quill; the first, second, and third quills longest, and nearly equal; the rest considerably graduated; tips of the lesser quills emarginate. Tail forked. Head crested. (Sw.)

The Larks are characterised by their having the hind-claw, which is like the fore-claws, somewhat straight, and longer than in the pipits and the wag-tails. The bill is straight, and rather short and strong, the upper mandible being arched without any notch, and not longer than the under. The nostrils, situated at the base of the bill, are oblong, and protected by small plumes and bristles directed forwards. The feathers on the back of this part of the body can be raised up at the will of the bird into the form of a crest.

Various species of Larks are found in all parts of the globe, and are everywhere distinguished by their vigilance and their singing. They are pelagic, and frequent the sandbanks, and other open places. The formation of their feet, except in a few instances, such as the wood-lark, does not adapt them to perch upon trees. They accordingly always build on the ground, making in general a rather slight though neat nest, and laying about five eggs, usually
of a grayish white, with specks of a brown colour. They frequently rear two broods of young during the summer.

The species are found in various parts of the world, including Britain, where some remain during the winter, the greater number flock together and migrate, either southward or to the seacoast. During these migrations immense numbers are caught in nets for the table, particularly on the continent, where small birds are more sought after for this purpose than in

**Localities—Europe and America.**

Mr. Swainson considers this as the Fissirostra type. It is found in various parts of Africa, but not in the south of Europe. It is the most abundant species in the vast continent (Temm.) the whole of Europe within the temperate zone, many parts of Asia, and the north of Africa. (Selby.)

*Calendula.* (Linn.)

Bill thick, much compressed; the culmen curved and convex; the commissure arched; the tip of the upper mandible wide above and inflexed. Wings long or moderate; the first quill very small and spurious; the second nearly equal to the third and fourth; lesser quills short, emarginate. Tail slightly forked. Lateral toes equal. Africa. The Denticirostra type—*C. magnumstris,* Ois. d'Afr., pl. 193. (Sw.)

Sub-genera—*Myosbrus,* Horst. *Bill as in Calendula.* Wings short, rounded; greater quills hardly longer than the secondaries and tertials; the first quill very short, half the length of the second, which is shorter than the third; the third, fourth, fifth, and sixth equal, and longest. Tail short, even. Legs long—*M. Javanica,* Linn. Tr., xiv. 1819.

*Brocardis,* Sw. (*Brochomyx.*)

*Bill as in Calendula.* Hind claw very short. Wings and tarsi much lengthened. Africa. (Sw.)

*Agrodroma.*

Bill slender, considerably compressed; both mandibles of equal length; the tip of the upper one not reflected over the lower, and with a small notch, almost obsolete. Wings long; the first four quills nearly equal; the rest rapidly diminishing, and emarginate at their tips; tertials lengthened, pointed, and emarginate at their tips; even. Legs long, pale, long, slender. Tarsus longer than the middle toe. Lateral toes equal, but the outer claw shorter than the inner. Colour brown, lark-like. Distribution universal. The Incisoria or pre-eminent type—*Agrodroma rufescens,* Earl., 1661, f. 1. (Sw.)

*Macromys.* (Sw.)

Bill slender, compressed, thrush-like, entire; nostrils large, naked, the aperture lateral. Wings short; the primaries not longer than the tertials, the first four of equal length; the rest rapidly diminishing, and emarginate at their tips; foot moderate. Feet enormous. Tarsus and hinder toes very long, and of equal length. Lateral toes unequal, the inner shortest. Africa. The Rascular type—*M. factoticola,* Ois. d'Afr., pl. 193; *M. factotum,* Sw., *Birds of West Africa,* ('Naturalis exotica,' Ornithology, vol. vii., p. 216.)

*Certíbulus.* (Sw.)

Bill slender, lengthened, more or less curved; nostrils round, naked. Wings very long; the first quill spurious; the next three nearly equal. Tail moderate, even. Feet lengthened; the lateral toes equal; length of the hinder claw variable, although typically short and straight. Africa. The Tenuirostra type—*Certíbulus longirostris,* Ois. d'Afr., pl. 192; *C. bifasciata,* Rüpp., 'Atlas,' plate 5; *C. nitens,* Sw., *Birds of West Africa,* (vol. vii., p. 215.).

Such are Mr. Swainson's drawings, and the arrangement of this sub-genus. (Felodilus.) The genus *Anthus,* Bechst., is placed by Mr. Swainson at the end of his sub-family

**Motacillina (Wagtail), under his family Spericidae (Warblers).**

**Fossil Larks.**

Dr. Buckland figures a lark (*Alauda*) among the land Mammifers and Birds of the third period of the Tertiary Series, in the first plate of the illustrations of his 'Bridge Water Treatise.' He had previously noticed the remains of the lark in Kirkdale Cave. ('Reliquiae Diluvianae,' pp. 19, 34, plate xi., ff. 24, 25.

ALBRECHT, WILHELM, was born in Germany, in 1786. He was one of the most distinguished pupils of Thaser, in the gymnasium at Mönchengladbach, and afterwards taught rural economy in Fellensberg's school at Hofwe.

In 1819 he was employed by the government of Nassau to edit a weekly publication devoted to agricultural subjects; and in the following year he was made director of an (ex-) experimental farm attached to the modern school. The experimental farm was transferred to Geisa, near Wiesbaden, and it became as long as distinguished as the source of agricultural improvements for the west of Germany. As it was found impossible constantly to employ all the pupils on the farm, Albrecht determined to open the school, during the six winter-months, for instruction in the theory of agriculture; while in April of each year the students went to the homes of their parents, or to some farming establishment, where they could familiarise themselves with the practical labour of an agriculturist. During the life of Albrecht the school was highly successful. "The best students for our institute," said he, "are young men from about sixteen to twenty-two, who after distinguishing themselves at the school, "he followed among them for some years at home, or on some well-managed farm: they bring a well-disposed mind, not fatigued with study, nor distracted by too many pursuits." While managing these establishments, Albrecht besides his weekly paper, edited the "Annals of the Agricultural Society of Nassau;" to which society he was perpetual secretary. Albrecht died in 1849, at his house in Franconia, whither he had retired on resigning the direction of the establishment at Geisa, a time previously. (Novelle Biographies Universelle, 1822.)

ALBUCA (from albus, white), a genus of plants belonging to the natural order Liliaceae. The species are mostly found at the Cape of Good Hope. They are cultivated in this country, and require the treatment of greenhouse bulbs. ALBURNUM, ANIMAL AND VEGETABLE. [Carruthers, S. 1.]

ALBUS. (From ALBANESES, a people in Phocis.) [Stokes, S. 1.]

ALDEHYDE. [Chemistry, S. 1.]

ALDEHYDIC ACID. [Chemistry, S. 1.]

ALHAGI (from the Arabic Aghul or Agul), a genus of plants belonging to the natural order Leguminosae. The species are under-blooms or herbs with simple leaves and small stipules. The flowers are red, and disposed in racemes along the peduncles.

A. MAURUENSIS is a native of the deserts of Egypt, Syria, Mesopotamia, and other countries of the East. This plant yields a species of manna, which is called Trumphin or Tropilin. It is chiefly gathered in the neighbourhood of Tabira where the plant grows abundantly. The manna is a natural exudation from the leaves and branches of the plant, and is most abundant during hot weather. In Arabia it is supposed that the manna falls from heaven on the plant. It first appears in the form of a small drop as of honey, which goes on increasing in size till it is about as large as a coriander seed. The manna yielded by this plant does not appear to be inferior in quality. It is exported to the present day in Persia, and is known by the name of Pemn Manan. It is employed as food for cattle. Two other species, *A. Candeloras* and *Nipalnianus,* are described by botanists, and cultivated in the greenhouses of this country.

ALASKA, a peninsula projecting from the N.W. coast of North America into the Pacific Ocean, and separating, together with the Aleutian Islands, the Kamchatska Sea from the Bering or Tcheking Sea. The peninsula is 1000 miles long and the isthmus which separates that lake from Cook's Inlet, may be considered as forming its natural N.E. boundary. A river, called Kortchak, or Bristol River, issues from the lake, and falls into Bristol Bay, or the Bay of Kane. From the S.W. side of the lake of Iliamna the peninsula extends in a general direction from E.N.E. to W.S.W. between 55° and 64° 40' N.lat.
between 153° and 163° 40' W. long. It is more than 410 miles long, and opposite the mouth of the river Nahnek (157° 50' W. long.) 110 miles wide, but its breadth decreases in proceeding farther west, where in some places it is hardly 20 miles wide. It terminates at the strait of Issanak, which separates it from the island of Oonmak.

The two coast-lines differ greatly in aspect. The south-eastern shores rise with a steep ascent, are indented with numerous bays, and islets, and marked by inlets, rocks, and reefs, partly under and partly above water, and in some places extending to a distance of ten, and nowhere less than five miles from the coast. Between these islands and the coast the sea is commonly very deep. The north-western shore is generally flat. When its term begins it becomes sandy and sandy beach, and has only a few open bays, but it is free from the inlets and shoals, and offers in many places an anchorage of moderate depth. A chain of mountains extends through the peninsula from the strait of Issanak to the islands of Ittanma along the south-eastern shores, but east of 155° W. long. its highest part is at a greater distance from the coast than to the west of that meridian. It contains several very elevated peaks towards its western extreme, and from four to six. All are covered with snow, but farther east it becomes considerably lower.

It is remarkable that in the western and more elevated portion of the chain, which consists mostly of volcanic rocks, and where some still active volcanoes exist, there occur four towns, the coast of the nine, in the mountainous regions, to such a depth, that their surface is not many feet above the sea-level; the soil in them consists of loose sand, and it appears likely that these depressions were once straits, and the most south-western part of the peninsula a series of islands, lying parallel to the 155° W. meridian, and resembling the eastern islands of the Alentian chain, but the straits have been filled up by sand in the process of time.

The low country along the Bay of Kanasoko consists mainly of sandy wetlands, and the marshes contain many swamps, and in others with moses. Several plants grow on it, and bushes of dwarf willow and alder, but no trees. Along the southern coast, especially east of 158°, also occur some level plains at the innermost recesses of the bays; they do not much differ in plants from the district just noticed, except that their vegetation is much more vigorous, and the bushes attain a greater height. The best harbour on the north-western shore is in the Bay of Moller (56° N. lat., and 160° 40' W. long.), between which and the Bay of Pavlovskaja the peninsula is narrowed to about 14 miles. Along the south-eastern coastal seaports are met with. The most considerable from west to east are Morjevaskaja, Belkowski, Pavlovskaja, the Bay of Wrangell (156° 30' W. long.), the best of them all, and also the Bay of Tsimly.

The Russians, who have a few settlements almost entirely inhabited by natives on both coasts, have introduced agriculture, and through no kind of grain succeeds, the inhabitants of the few dispersed villages raise considerable quantities of wheat and rye. Their domestic industry is principally from fishing, the sea abounding in cod, sole, turbot, and several kinds of mollusca. Whales are frequent along the northern coast, and rather rare on the southern. Morose in immense numbers visit the northern coast, and their teeth constitute the principal article of commerce, since the sea-otters, which formerly were very plentiful, have been nearly destroyed by the avidity of the inhabitants. Rein-deer, bears, and red foxes are the only large land beasts with success hunted. Their dogs, which are all also wolves, and a kind of mountain-sheep, perhaps also the musk-ox. Seals and sea-lions visit the deeper inlets, and afford to the inhabitants some additional articles of commerce.

The number of settlements made on this peninsula does not exceed ten. Those west of 155° W. long. are dependent in the establishment of Onogashika, and those east of it on that of Kodiak. The largest of those settlements is the village of Katmatokai, on the Bay of Katmai, which has 90 inhabitants.

(Latue's Voyage autour du Monde; Kruisenvagen's Voyage round the World; Ketzeboe's Voyage of Discovery to the south.

ALLAMANDA, a genus of plants belonging to the natural order Apocynaceae. It was named after Frederick Allamand, who journeyed in Guiana, in 1769, and afterwards in Russia. He was a correspondent of Linneus. The species of this genus are shrubs yielding a milky juice, with verticillate leaves, and many-flowered peduncles of large yellow flowers. They are worthy of cultivation on account of the beauty of their flowers and foliage. They are all natives of South America, and when cultivated require a strong position to make them thrive. An infusion of the leaves of A. catartica is said to act as a powerful purgative, and an overdose to produce poisonous effects.

And the late WILLIAM, was born in Edinburgh in 1739. After receiving his early education at the High School, he was placed with a coach-painter; but displaying a strong attachment to art, he was entered as a pupil in the Trustees' Academy, where Wilkie was his fellow-student. In 1757 he proceeded to London, where he became a student of the Royal Academy. In 1805 his first picture of a 'Gipsy Boy and Ass' appeared at the exhibition of that institution. Not succeeding in at once attracting public attention, Allan resolved to try his fortune abroad, and selected St. Petersburg for the scene of his experiment; incited partly, it is said, by the expectation of finding novel and picturesque objects for the exercise of his pencil. He remained in Russia nearly ten years, making occasional journeys to distant parts of the country, to Turkey, Tatar, the shores of the Black Sea, &c., and everywhere industriously employing himself in gathering materials for his art.

On his return to Scotland in 1814, he made a public exhibition of the rare sketches and finished pictures of Tartarian, Tartar, and Circassian scenes and costume. Among the pictures was a large one of 'Circassian Captives,' which at the suggestion of Sir Walter Scott was purchased by one hundred gentlemen, who subscribed ten guineas each; it fell to the lot of Sir Walter, who, being in possession of it, is. From this time Allan settled in his native city, sending regularly some of his works to the exhibition of the Royal Institution. For a while his pencil was chiefly employed on the country scenes to which he had travelled; he then turned to the annals of his native land, and for several years was mostly engaged in illustrating the history or the romance of Scotland. To this period belong the 'Murder of Archbishop Sharpes', 'Parting of Prince Charles Stuart and Sir Robert Macnamara,' 'Knox condemning Mary Queen of Scots,' 'Murder of the Regent Murray,' and others of his best works. In consequence of a disease in the eyes he was compelled for a year or two to cease from painting, and being advised to vary a change of climate, he visited Italy, Asia Minor, and Greece. On resuming his pencil, his 'Slave Market at Constantinople,' and pictures of a like kind, showed that he had profited by his travels.

Meanwhile he had been gaining the distinctions awarded to success in the Royal Academy. In 1825 he was elected an associate of the Royal Academy. In 1836 he became R.A. In 1838 he was chosen, on the death of Mr. Watson, to be president of the Scottish Academy. On the death of Wilkie in 1840 Allan was appointed to succeed him as her Majesty's Limner. Sir Allan received the honour of knighthood. Sir William Allan was best known by his Russian and Circassian genre pieces, and by his Scottish historical works. In all of them there is much skill and refinement, but in none any very evident marks of a high order of genius. But he was also a very successful painter of a special class of portraits, such, for instance, as his 'Scott in his Study Writing,' and its companion, 'Scott in his Study Reading,' and in his later years he essayed some very laborious task, the 'Battle of Preston Pans,' 'Nelson Boarding the San Nicolas,' and the 'Battle of Bannockburn,' a large painting, on which he was engaged at the time of his death. One of his last considerable works, 'Peter the Great teaching his Subjects the Art of Ship-building,' was a commission from the Emperor of Russia.

Sir William Allan died on the 23rd of February, 1850. As a painter he was generally acknowledged by his countrymen to be at the head of Scottish art, by right of his talent as well as his reputation.
follow the same profession. Having completed his education at St. Paul's school, he for a time practised as an usher in the college. He was a good hand at the violin, and returned to London in the hope of maintaining himself by his pencil. While acquiring the technicalities of his art he was often reduced to great straits. At first he was con-
strained to paint signs and transparents for blind-makers; and afterwards he became an assistant in the works of a firm to manufacture paintings for picture-dealers. Under the necessity of producing many showy pictures at low prices, he soon acquired considerable mechanical dexterity, and he was led not unnaturally to turn his hand to a more popular branch of art. After working for a while as assistant to Stanfield and others, he obtained the situation of principal scene-painter at the Olympic Theatre, where that establishment first came under the management of Sir John Vanbrugh. As his talents were well known and his vigorous pencil did much to secure the success of the brilliant spectacles which formed the distinguishing feature of the management. Allen's early oil-paintings were gene-

rally of small size, and represent quiet, homely, pastoral scenery, which was rendered with great delicacy, and a nice appreciation of the freshness of natural colour. But though they found purchasers among well-known patrons of art, his reputation extended slowly, and he attributed his tardy progress to the hardness of his pictures as being contrary to the usual exhibition of the Royal Academy. He joined himself therefore to the newly-founded Society of British Artists, and became one of its most ardent supporters. All his most important works were thenceforward exhibited in the first instance on its show-room, and naturally became very popular.

Allen did not attain the position his early pictures pro-
mised. His inclination and his forte lay towards pastoral scenery. He loved and he could well depict those fresh, open, country scenes, so characteristic of our 'home counties,' which Minton describes as affording constant delight to the city dweller. For these Allen had all a Lon-
don's relish, and while he painted them with continual reference to the reality, his pictures commanded the sympathy of his countrymen. His key work was his 'Chapel in the Churchyard,' which had obtained skill in producing those 'brilliant effects,' which are so attractive in conjunction with gas light and theatrical properties, he began to employ them in his pictures, and though he succeeded by such means in sparing himself much thought and labour while he rendered his pictures more attractive in the exhibition-room, it was at the expense of those higher qualities of truth and propriety which are essential to lasting fame. And the evil was fostered and strengthened by another influence under which he fell, which has tended to be altogether alien from that of the theatre. From the first establishment of the Art-Union his landscapes won the favour of the prize-holders. Seldom possessing any knowledge of art, their taste is commonly capricious and imitative; and Allen permitted himself to be driven by the pressure of his circumstances to paint more and more with a special regard to them. His earlier pictures have many admirable qualities, and his latest display great technical and manipulative skill; but his life was not one of artistic progress, and his is not a name that can permanently take a high place among the artists of England.

Allen died August 26, 1855, of disease of the heart, at the early age of 49; leaving a widow and eight children, for whom unhappily he had not been able to secure a sufficient provision.

ALLONBY. [Cumberland.]

ALLOTIN, ALANTOIC ACID. [Chemistry, S. 1.]

ALLOXAN, ALLOXANIC ACID, ALLOXANTIN. [Chemistry, S. 1.]

ALLYLE. [Chemistry, S. 2.]

ALMADINE. [Gamet.]

ALPINA, a genus of plants belonging to the natural order Zingiberaceae. The species have thick fleshy horizontal roots. The stems are numerous and perennial, with lanceolate leaves, having a silt ligulate sheath. The flowers are in panicles, or loose racemes or spikes. The tube of the corolla is short, the inner limb 1-lipped. The filament of the anther is bent. The fruit is capsular and 3-seeded, with winged seeds.

A. Galanga is a native of Sumatra, and is cultivated in the Indian Archipelago. Its roots are pungent, acid, and aromatic, and are often substituted for ginger. They are sold by druggists under the name of Galanga major. A plant related to, if not identical with, the A. excilata of

Linnæus, is called Coriandri in British Guiana, and is described by Dr. Hancock as a bitter pungent plant, and which he says is used to a great extent in medicine, diuretic and, in large doses as emetic. [Galanga]

ALTIRINCH. [Chem.]

ALUMINA. [Chemistry, S. 1.]

ALUMINUM. [Chemistry, S. 2.]

ALDAMIYAH. [Mesopotamia.]

ALDAMIYAH DISTRICT in Kurdistan. The town is situated upon a lofty isolated rock in 36° 47' N., lat. 43° 21' E. long. in a plain which is screened on the north and south by mountain-ranges and drained by the Ghara river. The northern range of Ghara is the more southern range called Ghara is high, well-wooded, and in parts precipitous and very difficult of access. It separates the Amadiyah district from the country of the mountain Kurds. The northern range, which is also well wooded but does not seem to be so high as the southern, forms the plain of Amadiyah from the extensive valley of Berwari.

The plain of Amadiyah is cut up into innumerable ravines by the torrents which rush down the mountains into the Ghara River, by which they are carried to the Zab. It is well wooded with the gall-bear oak and with fruit and forest trees. It contains many villages, which were formerly inhabited by Chaldean or Nestorian Christians and were very flourishing, but many of them have been deserted by the in-
digenous population owing to the oppression of the tyranny of their Turkish governors; most of those who remain have joined the Roman Catholic Church. Around the town and the villages are well-cultivated gardens and orchards. Tobacco, rice, grain, water-melons, fruit, and gall-nuts are among the products. Kurdistan and Turkish ob-
presure afford little encouragement to cultivate the land.

The town is described by Dr. Layard as a heap of ruins; porches, bazaars, baths, and habitations were laid open to their utmost recesses; every part seemed crumbling to ruin, dilapidated, and nearly deserted; for the population at the time of his visit, in August, had retired to their summer habita-
tions in the mountain valleys. The fort or castle, which is surrounded by walls flanked with towers, is considered of great antiquity. The town was defended by a small garrison. Amadiyah was formerly a place of con-
siderable importance and strength, and contained a very large and flourishing population. It was governed by hereditary pashas, who traced their descent from the Abbas-
cide Caliphs, and were on that account always regarded with religious respect by the Kurds. The ladies of their family enjoyed the title of Khan. Ismaiil Pasha, the last of these hereditary chiefs defended himself long against the Turks, who attacked him at his residence, surrounded by a wall, and after a long and obstinate resistance, took the place by assault. Amadiyah (which is said to mean 'Town of the Medes') is frequently mentioned by early Arab geographers and is considered to have had as its foundation, most probably dates from a very early epoch. Some have asserted that it was called Ecbalana. To a defaced bas-relief on the rock near the northern gate, Dr. Layard assigns the date of the Assaric kings. Amadiyah is proverbially unhealthy. Fever and agues are very prevalent in summer, at which season the population remove to the neighbouring mountains, in the valleys of which they live in tents and osaalis, or sheds made with boughs. The population has greatly diminished since the place became subject to the Turks.

(Dr. Layard's Nineveh and its Remains; Colonel Chesney's Expedition to the Euphrates and Tigris.)

AMALFI. The story of the discovery of a copy of the Pandecta at the siege of this place, a. d. 1137, is now con-
sidered entirely without foundation. (Savigny's Geschicht der Römischen Recht im Mittelalter, Heidelberg, 1851-53, 6 vols. 8vo.)

AMAND, Sr. [Chem.]

AMBLESE [Wustmoreland.]

AMELANCHIER (the Savvy name of the Medlar), a genus of plants belonging to the sub-order Pomeae (Pomacea, Lindley), of the order Rosaceae. It has a 5-cleft calyx with lanceolate petals, and an ovary of 10 cells, with a solitary ovule in each cell. The species are small trees, with simple serrated deciduous leaves, and racemes of white flowers.

A. vulgaris, the common species, is a native of rugged places throughout Europe. It is the Aconidium rotundifolium of Persoon.

A. Betyipium, the grape-pear or Canadian Medlar, is a
the best route for a railway from the Mississippi to the Pacific between the parallels of 38° and 48°. These expeditions, organized by the United States government, led by experienced and skilled leaders, have contributed very largely to American geog-

graphy, observations having been made from the Mississippi to the Pacific, between the parallels of 49° and 47°, 41° and 39°, and near the 40°, 35°, and 34°, touching upon the Pacific Ocean at Puget Sound, Sacramento, and San Diego. On the results of these labours the Secretary of War has reported, that "the route of the 32nd parallel is, of those surveyed, the most practicable and economical route from a railroad from the Mississippi River to the Pacific Ocean."

In British North America, an extensive region, including at least 119,000 square miles, remains almost completely unexplored. This region extends from the head-waters of the Saskatchewan River, and the foot of the Rocky Mountain range, and from the northern branch of the Saskatchewan to the parallel of 49°, which forms the boundary between the British possessions and the United States. The exploration of this portion of British America has been undertaken by Mr. Palliser, a traveller who has spent a considerable time in the neighbouring districts of the Upper Missouri. For the pur-
poses of this expedition the Lords of the Treasury, on the recommendation of the Secretary for the Colonies, have sanctioned the abilities of Lieutenant James Palliser, of the Royal Artillery, Mr. Bourgeau a botanist, and Dr. Hector a medical gentleman, have been associated with Mr. Palliser. The chief objects of exploration are to be, 1, the exploration of the water-parting between the plains of the Saskatchewan and the basin of the south branch of the Saskatchewan and its tributaries; 2, the exploration of the Rocky Mountains, for the purpose of ascertaining the most southerly pass across the Pacific; and 3, the exploration of the valleys within the Basin of the North-West Passage, in order to report on the natural features and general capabilities of the country, and construct a map of the routes. The expedition sailed on the 9th of May, 1857, and having arrived safely at New York, proceeded to Fort William on Lake Superior, and thence to Lake Winnipeg, taking part in the advance.

The great project of communication by a ship-channel between the Atlantic and Pacific has led to the investigation of routes across the narrow isthmus of Panama by different exploring parties, but no route has yet been discovered which will admit of a ship-channel being formed without locks or tunnels.

In South America, not long after the important journeys of Spix and Martius, three European travellers crossed the whole breadth of this continent, from the Pacific to the Atlantic, descending the Río de la Plata, and ascending the Parana and intrepid Orellana three centuries ago; namely, Lienz. Dawe, R.N., in 1828; Dr. Pöppig, in 1831; and Lieut. Smith, R.N., in 1834. Of these travellers Pöppig added most to our geographical knowledge. He went first to Chili, where he spent two years investigating the adjoining regions, and sailed to Lima, whence he ascended the high table-land of Peru, and descended thence by the eastern declivity of the Andes to the valley of the Huancay or Huallaga, where he remained nearly two years, during which he collected a great deal of information respecting the climate, productions, and geography of that country. From the Huallaga he passed down the river Marañon, and thence returned to Europe, after five years (1837 to 1838) of wandering in the wilde of the New World, laden with 17,000 specimens of dried plants, some hundred stuffed animals, many plants before unknown, 3000 descriptions of plants, and many sketches. His work is a most valuable addition to our knowledge of South America.

Nearly simultaneously, namely from 1826 to 1833, another extensive journey was accomplished by Alcide d'Ori-

bigny, who travelled through the Bandas Oriental, Patagonia, La Plata, Chili, Peru, and Bolivia, and published a very full account with many important observations.

More important still are the results of the great Surveying Expeditions of the Adventure and Beagle, 1825 to 1836, commanded by captains King, Stokes, and Fitzroy. The coast-surveys of this expedition were very extensive; in addition to which the Admiralty furnished the Surveyors with geographical information than any expedition since the voyages of Cook and Flinders. Very valuable collections in all departments of natural history were made by Charles Darwin, the naturalist of the expedition.

During the years 1835 to 1844 Sir Robert Schomburgk ex-
plor British Guyana and the country to the west as far as
the Orinoco and Casiquiare. In reaching the Upper Orinoco he was enabled to connect his observations with those of Humboldt, and to add to the series of facts, astronomically determined, along a line extending from the Atlantic to the Pacific. One of the most interesting of his discoveries is that of the water-lying named Victoria Regia, the most beautiful specimen of the flora of the Amazonas and its tributaries, which has so successfully been brought to Europe, and has been an object of admiration during several years.

In the same region, and extending over the whole of Venezuela, Colonel Codazzi, by order of the government of that country, has completed a survey, which is embodied in a valuable work and atlas, executed at Paris.

Prince Adalbert of Prussia has explored the Xingu and some other rivers and regions in the lower basin of the Amazonas, and visited by an English naturalist Weddell, has since explored the little-known regions between the upper course of the Plata and the Peruvian table-lands.

W. Bollanger and G. Smith, who since 1826 had been residing for a considerable time in the province of Tarapaca, Peru, have made us acquainted with a very remarkable region of South America, a full account of which was published in 1851 by Mr. Bollanger. In it he gives us the most remarkable facts about the deposits of nitrate of soda, salt, and other saline substances, and the Andes, have been well described. Mount Lirima, the highest peak of that portion of the Andes, is estimated at 22,000 feet, which, if correct, would place it above all other American mountains.

The provinces of La Plata have been well described by Sir Woodbine Parish, in a work published in 1869, of which a second edition, much enlarged, appeared early in 1858; and the French traveller Casteline, accompanied by the English naturalist Weddell, has since explored the little-known regions between the upper course of the Plata and the Peruvian table-lands.

"The shores of the mainland between Trinidad Island and the Gulf of Mexico have been charted and published by the Admiralty; but many of the West India Islands are still wanting to complete a wholesome knowledge of those seas."

"The United States are carrying on an elaborate survey of their own coasts, and to the northward of them; a part of the Bay of Fundy has been done by ourselves, as well as all the shores of Nova Scotia, Canada, and Newfoundland; and when these surveys are finished, we shall only want to complete the eastern coast of America, those of Labrador, and of Hudson's Bay, which, being in our possession, ought to appear on our charts with some degree of truth."

Since 1845, Captain Kellett, in H.M.S. Herald, has continued the survey of the western coasts from the equator northward, along Central America, Mexico, part of California, and other regions, and has thus completed the entire western coast-line of America. The Americans advance steadily with this coast survey.

Since the publication of the article America many political changes have taken place in the governments of North and South America. The present names of the various states, with their capitals, and capital town of each, are stated in the following table—which of however some of the figures are only approximations.
ANÆSTHETICS. [Materia Médica, S. 2.]

ANAPA, a sea-port town and fortress of Russian Circassia, situated on the eastern shore of the Black Sea, in 44° 28' N. lat., and 32° 15' E. long., is about 25 miles S.S.W. from the mouth of the Cuban; population, exclusive of the garrison, about 300. It was founded by the Turks in 1784, to protect their Tartar subjects on the left bank of the Kuban, as also to extend their influence over the Circassian tribes. The products of Circassia soon began to circulate through Anapa, as they did formerly through Taman, which was then recently occupied by the Russians. There is no harbour, but only a roadstead at Anapa. The imports are cotton and woolen goods, tobacco, and a few exports; viz. ex., buffalo, and cow hides; hare skins, fur; tallow, wax, &c.

The fortress of Anapa is built on a projecting crag, on the most north-western extremity of the Caucasian Mountains. The surface is smooth and slopes down in an extended plain on the north and east towards the Kuban. The walls towards the sea are 432 yards long, and the entire circumference exceeds 2 miles. To the south-west the walls are built upon a calcareous rock; those on the north and north-west are on a bed of sandstone. At certain points the wall is strengthened by bastions and turrets. In the corner of the north-western bastion is a small fortress, called the Bastion of St. John. The whole circuit is about 5,000 yards, and with the ditches about 1,500 yards in circumference. There is a well within the walls, a cistern, and a pond in the bay. The water is clear and sweet, and the soil is fertile. The chief products are wheat, barley, and corn. The town has about 300 houses, and the population is about 3,000. The town is well defended, and is a strong place of refuge in case of attack.

ANCUn, a delegation or province in the States of the Church, is bounded N. and W. by the province of Urbino, S. by the Adriatic Sea, and E. by the Province of Piacenza. Its greatest length is about 38 miles, and the breadth is about 16 miles. The area is 408 square miles, and the population in 1843 numbered 166,114. The surface is traversed by numerous offshoots of the Apennines, which are separated by fertile valleys. Of the rivers which are small, the principal are—the Misa, the lower part of which is in the province of Urbino—Pesarzo, and enters the sea at Sinigaglia; the Eino, which has its source in the province of Macerata; and the Pescara, which marks the boundary between this province and that of Macerata. Of the whole area of the province (380,904 acres), 103,016 acres are under cultivation; 65,780 acres are covered with plantations and copses, and the rest consists of olive-grounds, meadows, vineyards, forests, and uncultivated land. The amount of absolutely barren land is only 20 acres. The chief agricultural products are wheat, maize, hemp, hay, tobacco, wine, oil, and beans. Some silk is also produced. Sheep and hogs are reared in great numbers. There are also many horned sheep.

The province comprises the northern part of ancient Picenum, with a small portion of Umbria; these two provinces were separated by the Enea, now the Eino, which is the ancient river by which Latinus passed to Picenum, and was therefore the western limit of Italy on the side of the Adriatic until this was afterwards extended to the Rubicon. The province contains only a part of the old Marches of Ancona, which formerly extended from the ducy of Urbino on the north, to the Marches of Fermo on the south. The capital is Ancona. The other towns which require notice here are Jesi and Osimo.

Osimo, the ancient Autunium, and a bishop's see, is situated on a high hill in the midst of a beautiful and fertile country, 8 miles S. from Ancona, on the road to Loreto, in 43° 29' 30" N. lat., and 13° 27' 30" E. long., with a population of about 1,500. It is a healthy and well built place, with a cathedral dedicated to St. Tecla; a town-house containing a museum of ancient statues and inscriptions found in the neighborhood; a handsome episcopal palace; and several convents. Silk and woolen hosiery are manufactured. The population is about 8,000.

ANCUS, the GULF OF, extends between the mainland of South America and the island of Chiloé, from 41° 30' to 43° 30' S. lat., and from 72° 40' to 73° 40' W. long. It communicates with the Pacific Ocean by the Narrows of Chacao, which are of considerable depth, but at some places hardly a mile wide. On the south of the island of Chiloé it is connected with the Pacific by the wide opening which occurs between the Chonos Archipelago and the island, which is about 160 miles wide, but at some places scarcely a mile. The narrowest part, which is near the island, is nearly 160 miles long (including its expansion towards the north, which is called Reloncavi Sound), and at an average 60 miles wide. Its shores are everywhere high, and formed by rocks.
In the middle of the gulf, between 42° 10' and 43° 50' is a great number of high rocky islands and islets. The southern point of the Bay of Ancud is in some maps named the Gulf of Corevados. (Surroving Voyages of the Adventure and Beagle.)

ANGLER, HENRY WILLIAM PAGET, MARQUIS OF, eldest son of Henry, first Earl of Uxbridge, was born May 28, 1788, educated at Harrow and Christchurch, Oxford; and entered Parliament as member for the Caermarvon boroughs in 1790. His predilection was however for a military life, and it found free scope at the outbreak of the revolutionary war in 1793, when he eagerly set out to join his father's forces. He marched at first the Staffordshire Volunteers, but which was admitted into the establishment as the 80th foot. Of this regiment he was appointed lieutenant-colonel on its having made up its complement in 1793. At the same time he received the corresponding preferment in the army, the lieutenant-colonnel's commission bearing date September 12, 1793. In 1794 he joined the army of the Duke of York in Flanders, and greatly distinguished himself during the remainder of that campaign.

On his return to England, Lord Paget was transferred to the command of a cavalry regiment, and commenced the career which at no distant day caused him to be regarded as the first cavalry officer in the service. As commander of the cavalry he accompanied the Duke of York into Holland in 1795, and distinguished himself in a few opportunities of acquiring distinction, but in the general attack Lord Paget succeeded in defeating a much superior body of the enemy's cavalry; and in the retreat, where he occurred again, a signal advantage over an apparently larger force under General Simon. From this time he retained his home actively on the officer under whose cover he remained. He had been appointed Governor of Gibraltar, and was sent to Spain with two brigades of cavalry to join the army of Sir John Moore. In forming this junction General Paget was perfectly successful, and on the road he succeeded in cutting off a party of French posted at Rueda—this being his first official service in the English service of the French in Spain. On joining Sir John Moore the cavalry under Lord Paget was pushed forward, and on the same day, December 20, came up with a superior body of French cavalry, and defeated it, taking above 150 prisoners, including two lieutenant-colonels. These victories gave the English cavalry an amount of confidence in themselves and their commander, which in the subsequent retreat was of the utmost value. During the retreat Lord Paget with his cavalry formed the rearguard, and whenever the infantry and artillery could not be relied upon he received intelligence that the enemy had arrived, and that their cavalry were crossing the Esla. Lord Paget hastened to the ford, and directed the 10th Hussars under Captain Wall to charge the Imperial Guard, who had crossed the stream. The French Guard gave way, and the Duke of Wellington was afterwards awarded a considerable loss in killed, wounded, and prisoners, among the latter being General Lefebvre Desouzettes, commander of the Imperial Guard. At the battle of Corunna Lord Paget had the command of the reserve, and his charge in support of the right wing, which was menaced by a far superior force, decided the fortunes of the day.

Lord Paget returned to England in 1809, and did not again serve abroad during the Peninsular war. In 1810 he was divorced from his first wife, by whom he had had eight children. Soon after the divorce Lady Paget married the Duke of Argylly, and Lord Paget married Lady Cowley, who had just been divorced from Lord Cowley. In 1812 he succeeded, by the death of his father, to the title of Earl of Uxbridge.

In the early part of 1815 the Earl of Uxbridge commanded the troops collected in London for the suppression of the corn law riots; but a more important service soon devolved upon him. When Napoleon escaped from Elba, and startled Europe by the ease with which he was re-established, the armies of the allied sovereigns were at once set in motion against him. The Earl of Uxbridge was appointed commander of the cavalry of the English army, and his management of the service excited general admiration. At the battle of Waterloo his gallantry on horseback, the conspicuousness of the almost unqualified gallantry of which that field was the theatre. It was the final charge of the British brigade, led by the earl, that destroyed the famous French Guard, and with it he overthrew the emperor. Almost at the close of the battle a shot struck the earl on the knee, and it was found necessary to amputate his leg. The limb was buried in a garden by the field of battle, and some fragments of the bone were afterwards collected, with an inscription commemorating the circumstance, which is always one of the objects shown to visitors at Waterloo. The service rendered by the earl at Waterloo was generally recognised and duly rewarded. Immediately the despatches of the commander-in-chief, the Duke of Wellington, came to light, the dignity of Marquis of Anglesey, and nominated a Knight Grand Cross of the Order of the Bath; while he received from the emperors of Austria and Russia, and other European sovereigns, corresponding knighthood dignities. In 1818 he was elevated to the peerage of Anglesey, and in 1819 he attained the full rank of general; at the coronation of George IV. he held the office of Lord High Steward of England; and in 1820 he received the sinecure office of Captain of Cowes Castle.

After fifteen years of comparative inactivity Marquis of Anglesey formed one of his cabinet, having succeeded the Duke of Wellington as Master-General of the Ordnance; but this office he resigned in the following spring to become, under the ministry of the Duke of Wellington, Lord-Lieutenant of Ireland. The duties of this important station the marquis addressed himself with characteristic energy, and by his zeal, impartiality, and ardent temperance, won a remarkable share of popularity. But his ardour outran his discretion. He had already in conversation declared himself a confirmed Catholic, and was found to be inconvenient; and when, in December 1826, he wrote a letter to the Roman Catholic primate directly favourable to Roman Catholic emancipation, he was at once recalled to England. Thus he was removed from Dublin as a day of mourning; the shops were closed, business was suspended, and his embarkation was attended by large numbers of all classes of the citizens. In the House of Lords the marquis was a warm advocate of the measure which his letter had done much to bring about. In November, 1830, the Marquis of Anglesey was restored to his vice-regal office. But his popularity did not return to him. He set his face against the proceedings of O'Connell, and his former services were forgotten. A bill passed the English parliament to object for securing the public peace in Ireland led to great dissatisfaction: misunderstandings and recriminations occurred between O'Connell, who declared himself tricked, and the ministry, and in consequence Earl Grey resigned July, 1833; and with him the Marquis of Anglesey, who was regarded as the cause of the ministerial break-up, also quitted office. Of the thorough honesty of purpose of the marquis's administration of his vice-regal functions, after the temporary clamours against his name, there can be no doubt. That he displayed any high order of statesmanship there can be no pretension raised. The institution by which his tenure of office is most likely to be remembered is the Irish Board of Education, which was originated and carefully fostered by the greatest benefits conferred on Ireland in recent years.

From this time the marquis took little part in public affairs until the formation of the administration of Lord John Russell in July, 1846, when he again became Master-General of the Ordnance; the duties of which office he sedulously performed till February, 1852, when the Russell ministry was replaced by that of Lord Derby. He was made colonel of the Horse-Guards in 1842, and was advanced to the dignity of field-marshall in 1846. He died full of years and honours April 29, 1854. By his first wife the Marquis of Anglesey had issue two sons and six daughters; by his second wife he had six sons and four daughters. He was the father of the late Earl of Uxbridge, and as lord-lieutenant of Anglesey, by his eldest son the present marquis.

ANGOUVLÉ, DUC ET DUCHESSÉ D'. Louis Antoine de Bourbon, Duc d'Angoulême, and afterwards Dauphin of France, the son of the Comte d'Artois (afterwards king by the name of Charles X), was born at Versailles on the 6th of August, 1775, and died at Goëritz on the 3rd of June, 1844. He was fourteen years of age when the revolution broke out. The Comte d'Artois in order to protect by his absence those concessions which had been made to him, passed to England, followed by his two sons followed him to Turin, the court of their grandfather, where for some time they devoted themselves to the military sciences. In 1792 the young duke received a command in Germany, but attained no distinction. The success of this campaign induced him to return to a state
In 1814, when the Bourbon family returned to Paris, the Duke and Duchesse d'Angoulème took the ancient title of Dauphin. The decrees of the 29th of July, 1830, re-opened the road which was for the third time to conduct the royal family to the land of exile. They arrived in England on the 23rd of August, and were received as private individuals. Charles X. asked and obtained leave to take up his abode, when in Edinburgh, in Holyrood Palace.

They soon after removed to the continent, and fixed their residence at Göttingen, in Hanover. The duchess survived her husband seven years.

ANILINE. [CHEMISTRY, S. 2.]
ANISOINE. [CHEMISTRY, S. 2.]
ANISOLE. [CHEMISTRY, S. 2.]
ANISTYLANE. [CHEMISTRY, S. 2.]
ANNEXATION of the Kars district of Turkestan. Armenia, is situate on the right bank of the Araxes, a feeder of the Euphrates, in 40° 25' N. lat., 43° 34' E. long., at a distance of about 65 miles N.W. from Erivan. It was finally ceded to Russia, in 1828, which was the residence of the Armenian kings from the 8th century till the year 1084, when it was taken and ravaged by the Alp Arman. The Armenian patriarchs also resided in Anni from 993 to 1084. The town stood upon an area terminating on two sides in abrupt and rocky declivities; on the south is a deep ravine, in the bottom of which the Arpa flows: the area is open towards the north, on which side it is defended by a massive wall flanked with numerous towers. The towers are remarkable for the gigantic stones formed by huge blocks of red sandstone set into the masonry. The walls, towers, and churches are in good preservation; so much so, that at a distance the city does not seem deserted. Besides the buildings of the city itself, there are some, of the buildings of the church, for the few existing churches. All the public buildings display much splendour and architectural beauty, and the fritework of the arches is very rich. Some of the churches are decorated with rude wall-paintings representing scriptural and legendary subjects. There are also some of the buildings which are made of brick, but some are Turkish. The private houses of Annı are supposed to have been of an humble description, as none of them are left standing, and the whole area on which they stood is covered merely with mounds of loose stones. The city continued to exist in a poor state of repairs, till 1818, when it was completely destroyed by an earthquake. (Wilbraham's Travels in the Trans-Caucasian Provinces of Russia.)

ANNUITY. The restrictions imposed on contracts for annuities by the Statute 13 Geo. III, c. 141, have been removed, and parties are now left perfectly free to make their bargains in the terms on which they can agree. (17 and 18 Vict. c. 90.)

ANOPHILA, a family of insects, including the Apterae, a tribe of Aphides, and various forms of Juncius (Poneraeus) and Parasitic Insects of other authors. The researches which were commenced on this family by Dr. Leach have been carried on by Mr. Denny, and resulted in the discovery of a vast number of new forms. The result is that it has been found that the expression of a certain natural order for a useful purpose is accompanied by one, or more creatures belonging to this family, having a peculiar form in each species. Nearly 600 different forms of these curious insects, all formed in a manner which is described in the catalogue of the species which at present exist in the British Museum. In most cases but one species of the parasitic exists on one species of animal, but there are instances, as in the galls and galls of the several kinds in which a species of the bird is attacked by five species of Anophila. The best series of illustrations of these insects which exist are contained in Denny's 'Anophila Britannica,' published in 1842.

ANTARCTIC REGIONS. [POLAR COUNTRIES AND SEAS, S. 2.]
ANTHERIDIA, in Botany, organs found in many of the tribes of Cryptogamic or Flowerless Plants. They have been observed in the Characeae, Horse-Tails, Ferns, Mosses, and Algae, and are described by Kerner as the Phanerogamic or Flowering Plants. In the cells of which they are composed certain moving filaments are observed, which have received the name of Phytophors or Spermatozoids. Many of these phytors move by cilia attached to their length. For this reason to be inhabited till a.d. 1528, and forms, see REPRODUCTION in PLANTS and ANIMALS, S. 2.

ANTHRISCUS, a genus of plants belonging to the natural order Umbellifere and the tribe Scandineae. It is known by possessing little or no calyx, with heart-shaped petals bent down at the point; a fruit narrowed below the short beak, and without any ridges. The beak has five ridges.

A. syvustris, Wild Chervil, is known by its terminal stalked umbels, and its linear glabrous fruit with a short beak. It is a common weed in hedges and banks throughout Europe.

A. Ceratothion (Scandis Ceratothion), the Garden Chervil, is probably an escape from cultivation in England. It is common enough in waste places. [SCANDRIS.]

A. vulpigerus has the umbels lateral and stalked, and an ovoate hispid point. The leaves are slightly hairy. It is common in the waste places of Great Britain. (Babington's Manual of British Botany.)

ANTHROPOLIT the name given to Human Fossil Remains. Although at the same time it was thought that human remains were often found fossilised, the investigations of modern anatomists have shown that in most of these cases the supposition has been false. Daubenton first demonstrated that these bones had long been lost. All that remains of a gigantic human being belonged to a lower tribe of beings. The researches of Cuvier gave a clue by which all cases might be tested, and most of the earlier instances brought forward have been referred to their correct types.

Human fossil bones have, however, been discovered in the
Belgian bone-caverns, with bears, rodents, &c., and are figured by Dr. Schmerling, in his interesting work on the bones found in a cavern near Liège.

Dr. Buckland ('Brigewater Treatise') remarks that frequent discoveries have been made of human bones and remains, associated with cave-dwellings, in the caves of stalactite, at other times in beds of earthy materials, which are interspersed with bones of extinct species of quadrupeds. These cases, he thinks, may be explained by the common practice of mankind in all ages to bury their dead in such caverns. The subsequent inhabitants of a region often continue Dr. Buckland, 'that many caverns contained the bones of extinct species of other animals, dispersed through the same soil in which human bodies may, at any subsequent period, have been buried, affording no proof of the time when the bodies were introduced. Many of the caverns have been inhabited by savage tribes, who, for convenience of occupation, have repeatedly disturbed portions of soil in which their predecessors may have been buried. Such disturbances will explain the occasional admixture of fragments of human skeletons and the bones of modern quadrupeds with those of extinct species introduced at more early periods and by natural causes. Several accounts have been published within the last few years of human remains discovered within the caves of France and in the province of Liège, which are described as being of the same antiquity with the bones of hymen and other extinct quadrupeds that accompany them. Most of these may probably admit of explanation with respect to the caves just enumerated. In the case of caverns which form the channels of subterranean rivers, or which are subject to occasional inundations, another cause of admixture of human bones with the remains of animals of more ancient date may be found in the burials of such rivers by races of people.'

The same learned author observes that the most remarkable and only recorded case of human skeletons imbedded in a solid limestone rock is that on the shore of Guadalupe, adding that there is however no reason to consider these bones to be of high antiquity, as the whole of the rock is of very recent formation, and is composed of agglutinated fragments of shells and corals which inhabit the adjacent water. Such kind of stone is frequently formed in a few years from ondiment by the union of similar materials, on the shores of tropical seas. ('Brigewater Treatise', vol. i.)

One of these skeletons, described by Mr. König (Phil. Trans., 1814) is in the British Museum. See further as to the rock in which the skeletons are imbedded, 'Linn. Trans.,' 1816, vol. xii.

Dr. Lund published, some years ago, the discovery of human remains with those of Megatherium, &c.; and he was of opinion that the former were of the same epoch as those of the latter, and imbedded, he supposed, in the pebbles.

ANTIGORIN. [Chemistry, § 1.]

ANTOMMARCHI, FRANCESCO, a surgeon of some reputation as an anatomist, but more likely to be remembered in connection with his appointment to the Chair of Anatomy at the University of Bologna. In 1885 he received the degree of Doctor of Law, and in 1886 he was appointed Professor of Anatomy at the University of Bologna. He was a native of Corsica, studied medicine at the University of Bologna, and was afterwards appointed Professor of Anatomy at the University of Bologna.

In 1885 he was appointed Professor of Anatomy at the University of Bologna, and was later appointed Professor of Anatomy at the University of Bologna. He was a native of Corsica, studied medicine at the University of Bologna, and was afterwards appointed Professor of Anatomy at the University of Bologna.

His appointment rendered him the ablest assistant of his anatomical teacher, Mascagni. In 1888 he was appointed Professor of Anatomy at the University of Bologna, and was afterwards appointed Professor of Anatomy at the University of Bologna. He was a native of Corsica, studied medicine at the University of Bologna, and was afterwards appointed Professor of Anatomy at the University of Bologna.

He was a native of Corsica, studied medicine at the University of Bologna, and was afterwards appointed Professor of Anatomy at the University of Bologna.

APPERLEY, CHARLES JAMES, a writer on sporting subjects of considerable reputation, better known by the initials C.J.A., was born in 1822 at St. Peter's Village, near Wigan, son of Rev. Michael Apperley, a Welsh country gentleman, and was born at his father's seat of Pilsgronem, in Denbigshire, in the year 1777. At Rugby school he acquired some knowledge of the classical languages, and much more of the sports of the field. In 1801 he married the daughter of William Wynne, Esq., and in 1804 he took up his residence at Bolton Hall, once the country seat of Addison, in Warwickshire. Here he devoted himself so entirely to the chase that for some years his only business was to be in pursuit of the fox, which was forty miles to distant cover, and he contrived to defy the expenses of the sport by disposing of hunters, after he had ridden them for some time, to those of his friends whose knowledge of the hound was not so intimate as his, and who therefore could not find out their sport. He purchased the grounds of an untried animal. In 1831 he removed into Hampshire, and commenced farming on a large scale; and in the same year he began to write for the press. His contributions to sporting periodicals, especially to the Sporting Times, attracted so much attention that the circulation of the weekly paper was doubled in two years; and Mr. Pitman, the proprietor of the magazine, not only remunerated him handsomely, but also paid the expenses of his tours, and kept for him a stud of foxhounds. In 1833 he was appointed 'Hunting Tour,' which led to a suit by his representatives for advanced purchase, the result of which was that, to avoid a prison at home, Nimrod was compelled to take up his residence in France. In
AQUARIUM, a contraction for Aquaria vivarium, a term applied to arrangements of living aquatic animals and plants inhabiting either fresh or salt water. Although it has been known from the earliest times that animals living in water may be kept in small glass vessels for exhibition by the daily supply of fresh-water, the discoveries of modern chemistry have pointed out how animals may be kept living in only limited quantities of water which never demand renewing. The possibility of accomplishing this depends on the absolute balance which can be maintained in the water between the oxygen and vegetable kingdoms. The one set of these beings are engaged in giving off what the other requires, and in taking up what the other rejects. It is thus that the carbonic acid which is thrown off from the tissues of animals is taken up by the plants, and carbonic acid, supplied from the atmosphere. Whilst the plant gives off oxygen gas, and supplies the atmosphere with this element of its composition which is necessary to the life of animals. The relations which are thus found to exist on the large scale of the whole earth, the earth, are found also to occur in a jar of water. If an animal is placed in pure water it quickly exhausts the oxygen it contains, and gives out into it carbonic acid gas; the consequence is, that it dies. But if we place with the animal some plants in water, the carbonic acid given out by the animal will be taken up by the plant, and that the plant will give out oxygen in its place. Thus the water becomes cleared of its injurious compound, and the needed element, oxygen, is supplied. Such an arrangement in a small scale as is shown in an aquarium, is very productive.

The first experiments were made with fresh-water by Mr. N. B. Ward, and one of the earliest accounts of such an arrangement was given by Mr. Warington, chemist to the Apothecaries' Company. The latter found out, however, that it was not sufficient to have simply any kind of plants and animals; but that, in order to maintain the balance correctly, it was necessary that certain animals which lived on decomposing vegetable matter should be present. At certain seasons of the year this decomposing matter from the water-plants becomes so decided that the water would be rendered impure if this decomposition was not arrested. The cure for this was found in the addition of Fresh-Water Mollusca to the jars containing such substances as the golden-carp and stickback. Among the water-plants, the Valisneria, Callitriche, &c. The best kind of snails for this purpose are the various species of Planorba. Not only is it necessary that this latter precaution be taken to ensure the success of the experiment, but it is of importance to guard against the preponderance of animal life. Although in most cases it appears that there cannot be too many plants for the health of the animal as long as they grow healthily and do not decompose, yet it often happens that the excess of animals over plants in a jar will destroy the balance, and lead to the destruction of life.

Amongst the fresh-water plants adapted for growing in the Aquarium are the Valisneria spiralis, the various species of Chara, Anacystis, Aulacodictyon, Stichococcus, Alocha, Cottiae, Callitriche autumnalis, C. cornuta, Myriophyllum spicatum, and Ranunculus aquatilis. Such jars afford a good opportunity for cultivating the various species of fresh-water Conferve, which all assist in keeping the water pure.

Although these results have been known for many years, it is only recently that any attempts have been made to carry out the same plan with regard to marine animals and plants in sea-water. The difficulties, however, are greater in maintaining the balance between the plants and animals in sea-water than in fresh. This arises from the more arduous life, both of marine plants and animals, and the greater amount of disorganised matter which they throw from their surfaces. By care in the selection of sea-weeds, avoiding those which are large and throw off much sand from their surface, and not overcrowding the water with animal life, jars or tanks containing sea-animals and sea-plants can be easily managed. Mr. Warington recommends green sea-weeds, such as the species of Porphyra, &c. Mr. Gosse speaks favourably of the bubble, the Delisea, and the Delesseria. In jars or tanks containing these plants, various forms of sea-animals have been successfully kept for many months.

The greatest experiment of this kind which has hitherto been attempted is in a large glass-building that has been erected in the gardens of the Zoological Society, Regent's Park. It was opened to the public in May, 1853. This building contains an area of 60 feet by 25 feet. The sides
of this parallelogram are bounded by reservoirs of plate-glass, each being about 6 feet in length, and 2 feet 6 inches in depth. The depth of about 3 feet from the ground, so that each division presents as it were a sub-marine picture 'on the line,' and may be approached so closely that the minutest animals not microscopic, may be watched with the naked eye. The perfect success under circumstances which differ as little as possible from those of nature. The whole of these tanks are supplied with gravel, sand, rocks, and sea-weed, so as to imitate the rock-pools left on the seashore by a receding tide, which indeed they may be said to represent, but with the great advantage to the observer that instead of looking vertically into a cavity in which the light becomes less and less in proportion to the depth, he has here the means of examining each animal in its turn, under an effect which is not only most delightful in itself, but also most effective in throwing a perfect picture through perfectly transparent walls, affords the best possible position for investigating the structure and functions of the living beings contained in it.

The tanks contain fresh-water animals and marine animals. The fresh-water tanks present all the more common species of British Fishes, as the Pike, Tench, Perch, Roach, Rudd, Carp, Eel, Stickleback, Minnow, Gudgeon, &c. Some of the larger forms of fresh-water crustaceans, as the Crawfish, have also been introduced. With these have been placed a large variety of the fresh-water Mollusca, belonging to the genera Linneus, Planktus, Anodon, Unio, &c. These tanks have been occupied since Christmas, 1852, with scarcely any loss. Amongst the Radiate Animals, more remarkable to an observer fond of poetic description than the inhabitants of the tanks for causing the destruction than the Actinidea, and all experimenters agree that they are amongst the animals which may be most successfully kept in the Marine Aquarium. All the more common British species are now to be seen in the Regent's Park, and some of remarkable size and beauty. The Sertularian Zoophytes and the Polypoza are also there, but their animal inhabitants are too minute to be seen with the naked eye. Specimens of the Echinodermata, including several forms of Star-Fishes (Asterias), the Sea-Squirt (Ciona), the Sea-Urchin (Echinus), and other rare forms of this class of animals have been from time to time introduced. As was to be expected, the Mollusca thrive. In the sea they play the same part as in the fresh-water : they are the scavengers of the ocean. The Pinne, the Oyster, the Pecten, the Cockle, amongst bivalves; and the Whelk, the Periwinkle, with many other univalves, have demonstrated how large a field of observation is in store for those who shall labour amongst the innumerable species of the shells of the sea. The Nautilus has been brought back; and we may hope for the day on which the Antiquary may be able to publish a work on this subject.

The Articulata have been represented in these tanks by species of Lobster, Crab, Shrimp, and Prawn. Though many of these are inhabitants of the deep ocean, and only reward the labours of the dredger, yet they live perfectly well in the shallow lodgings provided for them by the Zoological Society. These facts demonstrate that amongst the Invertebrate tribes there is none whose habits may not be studied in the Aquarium.

With regard to fish it is found that those which live in shallow water thrive best in the Aquarium. The Cormorant (Cormophorus), the Fifteen-spined Stickleback, the Long-spined Cottas, two species of Blenny, the Goby, the Grey Mullow, and the Flat Fish have lived remarkably well.

AQUARIUM COMING ON.

ARABOIR, a town of Asia Minor, in the pashalik of Sivas, is situated on an elevated plateau between the Göl-Dagh and Sari-Chi-Chak branches of the Anti-Taurus [Antarirus]; at a distance of 16 miles N.W. from the junction of the Kara-Su and Murud-Su, on the caravan route from Aleppo to Trebizond, from which place respectively it is distant 270 and 186 miles. It is built amidst a forest of fruit-trees among which the White Mulberry is most common. The fruit of the mulberry is eaten fresh, and is said to be very disgusting, or it is made into a sweetmeat called Petmes, which is common all through Armenia. The soil in the neighbourhood where it is free from rocks yields fine crops of wheat. The town contains 4800 Turkish and 1200 Armenian families. A few years ago the Armenian population had 1000 hand-looms at work, weaving cotton goods from British yarn. This industry and the caravans trade rendered Arbog a thriving and populous town. Being highly baronial, iron-ore is abundant; and near the spot where the above-named two rivers meet and form the Euphrates, are the lead and copper-mines of Kaben-Maden. (Royal Geographical Society.)

ARAGO, FRANCOIS JEAN DOMINIQUE, was born in the commune of Estagel, near Perpignan, province of Roussillon (now the department of the Eastern Pyrenees), on the 20th of February, 1796. His father, a licentiate in law, supported a numerous family on the income derived from a small landed property. François, the son, acquired the rudiments of reading, writing, and vocal music at the primary school of his native place, and in private lessons at home. He became an eager reader, and at an early age conceived a passion for physical science. He was driven from home by the continual passing of troops on the march to or from the frontiers of Spain. When but seven years old he attacked with a lance the leader of a few Spanish troopers who had ridden into the village after a battle, and was only saved from a sabre-stroke by a pair of peasant lancers, who rushed on the young boy armed with hay-forks. His father having been appointed Treasurer of the Mint in Perpignan, the family removed to that town, where the boy entered as out-door pupil at the municipal college, and pursuing his literary studies, made himself acquainted with the classical authors of his native country. But walking one day on the ramps, a little incident occurred that confirmed his military inclinations. Seeing a youthful officer directing the repairs of the fortifications, Arago was so much impressed by the talk he overheard by what means it had been won, and was answered—By study at the Polytechnic School, which was open to those who had passed a preliminary examination. From that time Arago, then in his twelfth year, betook himself to the study of mathematics and geometry, not in elementary manuals, but in the original works of the best authors, and mastered their contents with characteristic energy. He soon outstripped the abbé who taught mathematics. The climate is cold in the winter months, and the young man who was telling him of the difficulties he met with in his studies: 'Keep on, sir, keep on, and conviction will come to you'; which was for me a ray of light. Instead of trying obstinately to comprehend at first sight the propositions that came before me, I kept on, and was astonished the next day at understanding perfectly that which, the evening before, had appeared to me wrapped in thick clouds.

Eighteen months Arago was ready for his examination, but the examiner having been detained by illness, a delay occurred, during which his friends sought to divert him from the pursuit he had chosen. He kept on, however, and studied the works of Euler and Laplace, and took lessons in languages that his having been a student at those establishments was essential to an officer. In the summer of 1803 he was examined by Monge at the University of Toulouse, and passed with high commendations first of his class. He repaired forthwith to Paris, and entered the Polytechnic School, where a few months later he was appointed from an examination by Legendre as from that at Toulousse. In either case, his readiness and familiarity with the subjects required, overcame the prejudices of the examiners.

He was studying for the artillery branch of the service when, in 1804, the post of Secretary to the Observatory
at Paris, then under Bouvard's direction, having fallen vacant, he was persuaded, but with great reluctance on his part, to undertake the duties. The temporary appointment, as he thought it, effected an entire change in his pursuits, for he remained attached to the Observatory for the rest of his life. At the instance of Laplace he worked with Biot, who was assistant-observer, at experimental researches for determining the refractive power of different gases—an inquiry commissioned, of course, to the Academy. One of these, a subject of a paper presented to the Academy of Sciences, and printed in their 'Mémoires' for 1806. In the same year the two young men were appointed by the government to extend and complete the measurement of the arc of the meridian from Dunkirk to Perpignan, a work which Delambre and Méchard had interrupted by the death of the latter. It was now to be extended from Barcelona to the Balearic Isles, and from thence to Formentera, by an irregular triangle, the measurement of which had been thought impossible. The fatigue of this survey in a wild mountain region, exposed to heat, cold, and storm, were excessive. For six months Arago was stationed on an elevated peak in the Deserto de las Palmas, watching for the light set up on Ivisa, owing to a defect in the mirror, was seldom visible. A space of about seventy-five square miles was all the ground he had for exercise; and two Carthusian monks, who, forgetting their vow of silence, used to ascend the mountain to converse with him in the depth of the night. The work involved frequent journeys, in which, apart from the fierce heats, much risk was incurred owing to the hostile feeling between France and Spain, and from parties of brigands. On two occasions a notorious robber-chief intruded himself as a nightly guard to the workmen.

The geodesic union from the mainland to Ibiza, and thence to Formentera—an arc of parallel of one degree and a half in one triangle—was successfully accomplished. Biot had returned to Paris, where, under the influence of the society, Arago was denounced as a spy. To escape the threatened violence, he obtained permission from the godfather to imprison himself in the castle of Belver. Having a safety-pass from the English Ambassador, he escaped in a half-decked boat to Algiers in July. In August he sailed for France in an Algerine frigate, and was in sight of the coast of Provence when the vessel was captured by a Spanish privateer, and carried into Rosas. He was again exposed to great danger: the authorities, bitterly suspicious, subjected him to repeated examinations, and consigned him to the hulks at Palamos, where his sufferings from want of food were, as he tells us, so great that he thought that his mother might then be looking up at their peaks, anxious for her son.

Being liberated on demand of the day, he sailed once more for France on September 38, and was off the port of Marseille when it was captured, caught by the mists, was drifted all across the Mediterranean to the coast of Africa. Arago landed at Boisie, and having travelled to Algiers, found a new day in power, who would have sent him to the galley but for a personal interference. Here he lingered, waiting for an opportunity to return home until June 1809, when he again sailed, and though chased by an English cruiser, landed at Marseille on the 2nd of July, with his manuscripts and instruments. For eleven months he had been tossed about on a perturbed sea, writing down in the midst of all disasters a narrative, interesting as a romance, in his 'L'histoire de ma Jeunesse.'

While yet in the lazaretto, he received a letter from Francis—the commencement of a lasting friendship with the statesman. Tenderly attached to his mother, his first visit was to her at Perpignan. She had mourned him as dead.

Arago hastened to Paris to communicate his observations to the Academy. Though under twenty-three years of age, he had already gained reputation by his labours and misfortunes; and the death of Lalande having left a vacancy in the Academy, he was elected a member by 47 out of 50 votes on the 17th of September 1809, by a majority of 36 votes, this being the Emperor. Thereafter Arago's influence was felt in the learned body; and his opposition to unworthy candidates brought him at times into collision with some of the most weighty of his colleagues. Before the close of 1809 he was appointed assistant-astronomer to the Observatory, and to succeed Monge in the chair of analytical mathematics at the Polytechnic School.

In 1811, taking up the researches of Malus, he read a paper to the Academy in which he showed that the light was greatly extended, and the changes described that take place in polarised rays on passing through different kinds of crystalline plates. The phenomena of colour, of dispersion, of reflection and refraction, were examined, and in a way that laid the foundation of the science of plane polarised and optics known as 'chromatic polarisation'; and the interesting fact was first announced, that 'while the light from a clouded sky undergoes no modification, that reflected from the sky in motion is always polarised, the intensity of the polarisation varying with the hour of the day and the position of the point with respect to the sun.'

In 1812, authorised by the Bureau des Longitudes, Arago commenced that course of lectures on astronomy and kindred subjects which he continued up to 1846 with the most brilliant success. The high and the low thronged to hear him; the learned to catch his animated manner and lucid style—the many to be charmed. As the Emperor Napoleon III. said, when a native at Ham, 'It is in a high degree those two faculties so difficult to meet with in the same man—that of being the grand-priest of science, and of being able to initiate the vulgar into its mysteries.'

The effect was heightened by the tall commanding form of the lecturer, his great voice, his solemn manner, his dark piercing eyes, shaded by thick bushy brows.

Conjointly with Gay-Lussac, Arago established the 'Annales de Chimie et de Physique' in 1816—a serial still published, and much valued by scientific men. In the same year he announced the result of his experiment, demonstrating the truth of the undulatory theory of light over the rival theory of vision. Young had shown in his experiments that the interference of an opaque screen in the path of a ray under certain circumstances produced the formation of fringes. Arago found that the ray was only retarded, and that by a modification of the apparatus the fringes were still discernible.

In 1816, also, Arago for the first time visited England, where he made the most brilliant of Young and other eminent men of science. With a Frenchman's feeling, he had a painful dislike to hear any allusion to the battle of Waterloo; and while in London he positively refused an invitation to see Waterloo Bridge. His entertainers adopted the stratagem of proposing an excursion on the Thames, which, being accepted, the party descended the river admiring the prospect, and presently coming to the imposing structure of granite then stretching fresh and new from side to side, the party stopped, and a French voice was heard saying, 'Give me the trick, and replied—"Your bridge has at least an arch too many; and that one, to be in its place, should be transported to Berlin.'

Another task commenced by Arago in 1818, again in connexion with Biot, was the construction of the French arch with the English arc by a system of signals and measurements from one side of the channel to the other. The results, together with those of the Spanish triangulation, were placed by order of the Bureau des Longitudes, in a volume entitled 'Recueil d'Observations Géodésiques Astronomiques, et Physiques.' In 1819, jointly with Fresnel, Arago published a series of experiments on the action exercised by polarised rays on each other, singularly interesting. This was the first test in which the complete theory of the refracting powers of bodies no longer existing was proved. Space fails here to give the details; but it was by means of these experiments that Fresnel was enabled to give a complete explanation of the production of colours in crystalline plates, which had been referred by Young to the interference of transmitted rays. The experiments, the results of which had been produced happy results; for Arago, though rich in inventive faculty, lacked the perseverence which works out to its ultimate consequences. "We complete one another," he says, "we have to point out the difficulty, and Fresnel how to conquer it."

In 1809 Arago took up a new line of inquiry. Having witnessed a demonstration of Oersted's discovery at Geneva, he repeated it before the Academy, and with further results. The Danish philosophers, thinking of passing along a wire would deflect a magnetic needle: Arago found that non-magnetic substances were equally affected; that bars of iron and steel became temporary magnets, and lost their magnetism with the cessation of the
current. He proved moreover the best magnet to be a steel bar inclosed by a helix of copper-wire, to which we owe the discovery of the electro-magnet, and all that has since been accomplished thereby. Four years later other facts were published. Arago showed that a magnet not magnetic in position exert a powerful influence on the magnetic needle, particularly when in movement. Such metals appeared to become magnetic by mechanical motion—a phenomenon which has been referred by Faraday to general laws of magnetic induction.

In 1829 Arago was chosen a member of the Bureau des Longitudes, and from 1834 till his death the "Annales," published by the board, contained a notice on some scientific subjects. In this period he published, "They never always be repurposed," says M. Combes, president of the academy, "with the same pleasure by men of science and by the ordinary reader. In them we find an admirable clearness, with an erudition as correct as it is extensive, and joined thereto the most rigorous accuracy in the statement of the phenomena, and the consequences which result from them."

Arago won the position and honour he most prized in 1830, when on the death of Fourier he was elected Perpetual Secretary of the Academy. And now the duty devolved upon him of writing those "sketches" of deceased members which are among the most interesting of his literary productions—graceful in style, and abundant in anecdote and illustration. They appeared to be written with a fluent pen; but they are not a mere sketch, and often a full expression of his felicity of expression by real and repeated hard work of mind and hand. In the same year he was appointed director of the Observatory.

In 1834 Arago visited England a second time, and attended the meeting of the British Association at Edinburgh. He continued his scientific researches, among which are—the discovery of a neutral point in the polarisation of the atmosphere—determination of the synchronous perturbations of the magnetic needle at places wide apart, by observations carried on simultaneously with Kupffer at Kasaan—and the suggestion of a decisive proof of the truth of the undulatory theory, which has since been demonstrated by Foucault—besides other subjects of poetry and astronomy.

The later years of Arago's life were passed amid much bodily suffering, when, with falling sight and afflicted with diabetes, he set himself to finish his incomplete papers. In the summer of 1853 he went, attended by his niece, to his native place, seeking relief in change of air; but the hope was disappointed: he returned to Paris and died on the 2nd of October, aged 67. He was buried in the cemetery of Père-la-Chaise, followed by a concourse of 3000 persons to the grave, where Flourens pronounced the oration.

Arago was elected a foreign member of the Royal Society in 1818. In 1822 their Copley medal was awarded to him for his "discovery of the magnetic properties of substances not containing iron"; and their Rumford medal in 1850, for his "experimental investigations of the law of light."

The Royal Astronomical Society elected him one of their associates in 1822; he was also a member of some of the leading scientific societies on the continent. Arago was once married: his wife died in 1810, leaving two sons, who still survive. He had been accused of hoarding up wealth, but he left no other fortune to his relatives than a name and reputation of which they may be justly proud. His high works are easily accessible, as they have been collected and published in a series of octavo volumes in French and English. It is a matter that he has left a narrative of his later years, not less interesting than that to which reference has been made above, for publication when the fitting time shall arrive.

In 1860 Arago was an impromptu nature at times involved Arago in bitter controversies with other savants, in which he too often lost sight of truth and justice. It is certain also that he was occasionally tempted to sacrifice accuracy to effect. In politics he was an ardent republican, to which he was led by his election to the Chamber of Deputies after the 'Three Days' of July, 1830. By his eloquent advocacy the observatory of Paris was placed on its proper footing among the observatories of Europe, and the works of Laplace and Fermat were published at the national expense. His works were composed in half a century. To Menon, of Tremolieres, the Italian philosopher, owed his return to Naples from a wearisome exile. In 1840 he became a member of the Council-General of the Seine; and in 1848 he was chosen into the Provisional Government, in which he discharged the functions of minister of war and marine. In bitterness of spirit he despaired of the republic on witnessing the popular caprice. He refused to take the oath of allegiance after the coup-d'état of 1851, and justified his refusal in a memorable letter to the government, which elicited a concession alike gratifying to his conscience as a political philosopher. "A special exception," so wrote the minister authorised by the Prince-President, "would be made in favor of a philosopher whose labours had rendered France illustrious, and whose existence the government would be loth to sadden."

ARAGUAYA, one of the largest and most important rivers in the interior of Brazil, though up to the present time it is not much navigated, because the countries along its banks are not unclaimed, except at a few isolated places. It divides the province of Goyaz, which lies east of it, from Matto Grosso, which extends west of its course. It rises in the Serra de Santa Martha, south of 18° S. l., in a lake, and runs under the name of Cayapo about 160 miles, single it unites with Rio Claro, which traverses the town of Villas Boas, the capital of Goyaz, and takes the name of Araguaya. Continuing in a northern direction to about 12° 30' S. l., the river divides into two branches, which do not re-unit until 9° 30'. The island which is thus formed is called Ilha de Santa Anna, or Bannanal. It is more than 200 miles long, and at an average 30 miles wide, so that it covers a surface of more than 6000 square miles. The western arm of the river preserves the name of Araguaya, whilst the eastern is called Furo. The latter is most used by the boatais and Creix from the Pará; and at a very few places on its shores the Portuguese settlers have formed establishments, whilst none exist on the western arm. In both arms some falls occur, but they are not considerable. After its arms have re-united, the river runs to 6° S. l., where it joins the Tocantins. The whole course of the river probably does not fall much short of 1000 miles, and it receives the waters of several navigable tributaries south of 10° S. l., among which the Vermelho and Ceix from the Pará, and the Rio das Mortes and San John from the left, are the largest. (Henderson's History of Brazil.)

ARANIDE, the first family of the first order of the class Arachnida. [Arachnida.] They are also called Spring Arachnida, from their peculiar long filamcntous cords with which they form their nets and webs. It is to this family that the term Spider is more especially applied; and scientifically it embraces all those creatures which are commonly called Spiders. All these are embraced under the old Linnean genus Araneus. Externally this family is distinguished by the following characters:—The palpi resemble small feet without a claw at the tip, terminated at most in the females by a small hook, but in the males supporting various appendages, more or less complicated, which are directed with the function of reproduction in this family. The frontal claws are terminated by a movable hook which curves downward, and has on its under-side a little slit for the emission of a poisonous fluid which is secreted in a gland of the preceding joint. Thexma-llae are never more than two in number; the tongue is of a single piece, always external, and situated between the maxillae, and more or less square, triangular, or semicircular...
the body is furnished with four or six nipples, fleshy at the tips, round or conical, jointed, placed close together, and pierced at the extremity with an immense number of minute orifices for the discharge of silken threads, which are produced from matter formed in internal reservoirs. These are called spinnerets. The legs vary in length, but are composed of seven joints, of which the first two form the haunch, the next the femur, the fourth and fifth the tibia, and the two others the tarsi. The last is ordinarily terminated by two claws, generally toothed beneath, and by a third, smaller claw which is not toothed.

The most remarkable function performed by the spinneret is that of producing silken threads by means of the spinnerets before described and figured. From each one of the minute orifices of the spinneret there exude as many little drops of a liquid, which becoming dry in motion occurs in contact with the air, forms so many delicate threads. Immediately after the filaments have passed out of the pores of the spinneret they unite first together and then with those of the neighbouring spinnerets to form a common thread; so that the thread of the spider, when it suspends itself from any object, is composed of an immense number of minute filaments, amounting even to many thousands, each of which is of such extreme tenuity that the naked eye cannot detect them till they are formed into a common thread. The spinnerets of the same spider differ in structure, and Lyonet has shown that one set of spinnerets is employed in producing threads which are glutinous, whilst another set produces threads which are smooth. This may be seen by throwing a little dust on a spider's web, such as that of Epeira diadema, when it will be found that it adheres to the threads which are spirally disposed, but not to those that radiate from the centre to the circumference. These last are also found to be stronger than the spiral ones.

Thus caught offers to treat a resistance, so that the spider becomes endangered, he retires for a time from the contest to renew his strength, leaving his victim secure in his meshes, and gradually getting exhausted from the attempts it makes to escape. When the spider returns he frequently twists the web round and round the body of his victim, and then either at once commences to make a meal of him, or waits till his appetite suggests the proper time for feeding.

Although Spiders are not provided with wings, and are consequently incapable of flight, they have a power of ballooning with their silken threads, by means of which they can make distant journeys through the atmosphere. These ariel excursions, which appear to result from an instinctive desire to seek some more favourable spot for the gratification of their appetite or other cause, are undertaken when the weather is bright and serene, especially in the autumn, both by adult and immature individuals of many species, and are effected in the following way:—They first mount to the summit of an object, and then raise themselves still higher by straightening their limbs; the abdomen is then elevated into an almost perpendicular position, and they emit from their spinnerets a small quantity of viscid fluid, which is drawn into fine lines by the ascending current of air from below keeps impinging till the animals, finding themselves acted on with sufficient force, quit their hold of the earth and mount into the air. It has been sometimes stated that spiders can forcibly propel or dart out lines from their spinnerets; but when placed on sprigs set upright in glass vessels, with perpendicular sides, all their efforts to escape are unavailing.

The webs named gossamer are composed of lines spun by spiders, which on being brought into contact by the action of a gentle air, adhere together, till by continual addition they are accumulated into irregular white flakes and masses of considerable extent. The poisonous effects of the wounds of spiders are produced by means of the mandibles, or frontal claws, which are each armed with a moveable and extremely sharp hook, near to the point of which is a minute orifice, whence there is poured out a drop of poison into the wound. This orifice, which is very difficult to detect, communicates with a canal in the interior of the mandible; this canal proceeds from a gland situated in the interspace of the muscles of the thorax. The gland consists of a vesicle having internally a number of spiral filaments, which are connected together by a membrane in the form of a bag. Although dreadful stories are related of the effects of the bites of spiders on the human body, it appears from experiments made by Mr.
Blackwall on British Spiders, that none of these have the power of producing any ill effects on human beings. There is still wanting good evidence on which to rest a charge of poisoning man by biting him, even against the larger forms of spiders, which inhabit tropical climates.

A curious feature in the history of spiders is the power they possess of removing their webs after they have been broken off. This power, however, is not confined to spiders, as we find it in the Crustacea [CRAUSETA], and even in the vertebrate animals amongst the Amphibia. [AMPHIBIA]. In the case of the spiders, it is never a part of a limb which is reproduced, but if a part of a leg is removed, it proceeds to throw off the remainder, and after the next molt the missing member reappears.

The species of the family Araneidae are very numerous and have been arranged by naturalists under several genera. They have been investigated with great care by M. Walckenaer, who has made them the special study of his life, and has drawn up a natural arrangement of them according to their structure and habits of life. A synopsis of this arrangement we subjoin, as by a little study it will furnish an insight into the surprisingly varied habits of this family:—

**Araneidae**, hiding in holes and fissures.

**Ctenidae**, including themselves in silken tubes.

**Ccelidocara**, sheltering themselves in small cells.

**Cyclococha**, running swiftly to catch their prey.

**Salthotera**, leaping and springing with agility to seize their prey.

**Laterobolus**, walking and running sideways or backwards, occasionally throwing out threads to entrap their prey.

**Nictitela**, going abroad, but making a web for their nests, where the larvae threads to entrap their prey.

**Furcula**, going abroad, but spreading long threads of silk about the places where they prowl in order to entrap their prey.

**Tatarida**, splashing great webs of a close texture like hemlocks, and dwelling therein to catch their prey.

**Orthinidae**, spreading abroad webs of a regular and open texture, either orbicular or spiral, and remaining in the middle or on one side to catch their prey.

**Reticulidae**, splashing webs of an open meshwork and of an irregular form, and remaining in the middle or on one side to catch their prey.

**Neocosa**, swimming in water, and spreading their filaments to entrap their prey.

**Aquaticidae**, living in water.

(Cyclopoidea of Anatomy and Physiology, article *Arachnida*; Blackwall, in Report of British Association, 1844; Owen's Lectures on Comparative Anatomy; Cuvier's Régne Animal; Insect Architecture, in Library of Entertaining Knowledge.)

ARBITRATION. The defects in the law, which permitted any agreement to refer disputes to arbitration, if disregarded by any of the parties thereto, to be of no avail, and which allowed arbitrations to come to an end by the death of arbiters or umpires, or the refusal of any of the parties to proceed therein, have been remedied by the Common Law Procedure Act, 1854. (Blackstone's Commentaries, Mr. Kerr's ed., vol. iii., p. 17.)

ARCET-TIHY. [TOZOTUS, S. 1.]

ARCHES, COURT OF. The jurisdiction of this Court in Testamentary and Matrimonial Causes has been transferred partly to the Court of Probate (20 & 21 Vict. c. 77), and partly to the Court for Divorce and Matrimonial Causes (20 & 21 Vict. c. 85); and as no suit for subtraction of legacies, (20 & 21 Vict. c. 77 s. 23), or for defamation (18 & 19 Vict. c. 41), can now be entered before this Court, whatever its jurisdiction is confined to few peculiar cases, particularly connected with the Established Church. (Blackst. 'Comm.' Mr. Kerr's ed. vol. iii. p. 93.)

ARCHITECTURE. [PUBLIC BUILDINGS.]

ARCTIC REGIONS. [NORTH-WEST PASSAGE, S. 2.]

ARDEA, ARDEIDÆ. [HERONS.]

ARENIOLA, a genus of Annellids Annellida, referred by Cuvier to the Dorsibranchiate class on account of their external gills. The general structure and habits of the genus determine most naturalists in placing it with the Terricolous Annellida. [ANNELIDA.]
The gills are branched, and placed upon the rings of the middle part of the body only. The mouth is flexely, more or less dilatable, but there are no discernible teeth, tentacles, or eyes. The posterior extremity of the body has not only no gills, but is devoid of the silky bristles which are found on every other part.

**A. Pectinurus**, the Leb or Lug-Worm, is the most common species. It is found very abundantly in the sand of the sea-shore, where its habits afford a close resemblance to those of the earth-worm away from the shore. It is bigger than the earth-worm, sometimes being found nearly a foot in length. It is of a reddish colour, and When touched throws out a quantity of yellow fluid which stains the hand. It is employed by fishermen as bait for various kinds of sea-fish.

AREOLAR TISSUE. [TISSUES, OVMAC, S. 1.]

ARGUS, a genus of Entomostracous Crustacea, belonging to the section Pectincola. There is but one species of this genus, the *A. foliaceus*. This little creature is not unknown to fishermen, as it is frequently found parasitic upon various kinds of fish. It was first described by Baker in his 'Employment for the Microscope,' in 1763, under the name of the "Loose of the Carp and Danistickle or TrickLack."

It is about the tenth of an inch in length, and is almost as broad as it is long. The head is in the form of a circular or disc-shaped shield. The antennae are short, thick, and two-jointed. Instead of a second pair of foot-jaws it has a pair of circular or disc-shaped suckers, by means of which it attaches itself to the animals on which it is parasitic. These suckers
is smooth and polished. They are composed of three distinct membranes, which are super-imposed one upon the other, and are termed by biologists the tunica, the media, and the adventitia, each of these membranes is called a tunic, or coat, and each possesses a peculiar structure, and performs a separate function in the circulation of the blood.

1. The internal tunic consists of a membrane, colourless, nearly transparent, and so firm, that it is impossible for it to resist to press more than any of the others the bursting of the artery by the current of the blood; for if, in a living animal, the other coats be entirely removed, this alone is found capable of sustaining the impetus of the circulation, and of preventing its exhaustion.

2. The middle tunic, called also the fibrous and the muscular, is composed of yellowish fibres, which pass in an oblique direction around the calibre of the vessel, forming the segments of circles which are so joined as to produce complete rings. In the larger trunks, several layers of these fibres can be raised in succession by the forceps, so that this coat is of considerable thickness, and it is proportionally thicker in the small branches than in the large trunks. This coat is firm, solid, and highly elastic. It is the main tunic by which the artery resists dilatation in the transverse direction, which it does so effectually that when the left ventricle of the heart propels a fresh current of blood into the aorta, the tunica and no other part of the vessel is perceptible. The characteristic property of the fibrous coat is its elasticity. If it be mechanically irritated, or if a chemical stimulant, such as ardent spirit or ammonia, be applied to it, the vessel contracts forcibly upon its contents. The contractile power, which is so necessary to the muscular coat, engages the minds of physicians to believe that the fibrous tunic consists of muscular fibres; but careful examination has shown that its organisation possesses nothing in common with that of the muscular tissue, while chemical analysis has demonstrated that it contains no fibrin, which is the basis of most of the muscular coats.

3. The external tunic, called also the cellular, consists of small whitish fibres, very dense and tough, interlaced together in every direction. It is much thicker in the large trunks than in the small branches, the reverse of the fibrous coat. Its outer surface is covered by a loose and flaccid cellular substance, which connects the artery with the surrounding parts, and particularly with the sheath of the vessel. Its firmness and resistance are so great that it is not divided however firmly a ligature may be placed around the artery; and its elasticity, especially in the longitudinal direction is so remarkable that it has been called, by way of eminence, the elastic coat.

Arteries are themselves abundantly supplied with arteries, constituting their nutrient vessels, and called Vasa Vasorum; but these nutrient vessels of the artery form but few anastomoses, that is, few communications with any other arteries. The principal nerves of arteries are derived from the ganglionic or plexiform system, but with these are mingled branches derived from the sensitive or the animal system. [Nerv.] Accordingly, under ordinary circumstances, arteries carry on their functions independently of any influence derived from the brain and spinal cord, but they are capable of being affected by agents applied to those organs.

Among the physical properties of arteries, the most important are their extensibility and their elasticity. Their extensibility is chiefly in the direction of their length. After an artery has been extended, either lengthwise or transversely, it suddenly retracts on itself when the extending force is removed. If the finger be forcibly introduced into the section of a large artery, the sides of the vessel re-act on the finger, and proportionally compress it. If an artery be divided in the dead body, though emptied of its contents, it maintains its cylindrical form, and preserves its capacity unimpaired. The elastic property on which these phenomena depend is common to all the coats, but it is greatest in the external tunica and least in the internal tunic, and it is also much greater in the large trunks than in the small branches.

The most important vital property of the artery is its contractility, that is, its power of diminishing its capacity, or of approximating its parieties, and thus proportionally acting back upon the general circulation. The function of the elasticity is to prevent any of these phenomena above in the larger arteries in any degree; but it resides chiefly in the largest divisions of the arterial branches, that is, the capillary vessels.

[Capillary Vessels.]

ASHURTON, ALEXANDER BARING, BARON, was born October 27, 1774, and was the second son of Sir Francis
Baring, Bart., an eminent merchant in the city of London. He was removed from school at a rather early age, and probably during his apprenticeship in the firm of his father, he completed his commercial training. He was sent to the United States, where, and in Canada, he for some years conducted the American business of the firm. Here he acquired much of that wide and varied commercial knowledge which he afterwards exhibited with spirit and sagacity on all matters connected with trade and commerce. In 1798 he married the daughter of William Bingham, Esq., Senator of the United States; and on the death of his father in 1810, became the head of the great firm of Baring, Brothers and Co.

Mr. Baring entered Parliament in 1812 as member for Taunton, which town he continued to represent till 1820, when he was returned for Callington, and remained its representative till his death, in 1829. Before the Reform Bill of 1832 was introduced, he was one of the leaders of the Reform party. Prior to the introduction of the Reform Bill Mr. Baring had voted steadily with the whig party; but he warmly opposed that measure, and in future ranked among the supporters of Sir Robert Peel. When the Reform Bill was passed in December, 1834, he acknowledged the advantage which he had derived from the adhesion of his prosectyle, by introducing Mr. Baring into his Cabinet as President of the Board of Trade and Master of the Mint. The appointment was received with considerable surprise; it was generally supposed that Mr. Baring would have been appointed to the House of Commons, where Mr. Baring had long been regarded as a high authority on all commercial subjects. But the ministry had but a short tenure of office, Peel resigned in April, 1835, and the President of the Board of trade continued to perform his duties. On the resignation of Lord Ashburton, William Baring was created Baron Ashburton. When Sir Robert Peel returned to office, September 1841, the differences of the United States respecting the boundary question excited some anxiety, and Peel requested Lord Ashburton to proceed to America as special commissioner, with powers to conclude a definite treaty. Both in England and America the nomination was received with satisfaction; and Lord Ashburton conducted the negotiations in so conciliatory a spirit, that Sir Robert Peel, on the opening of 1842, felt able to announce that a treaty had been concluded with the United States, in which "the adjustment of the boundary question was far more favourable to this country than the award of the King of the Netherlands," and that the other points under discussion between the two governments had been arranged in an equally satisfactory manner. In the House of Lords, Lord Ashburton continued to support the policy of Sir Robert Peel until that statesman brought forward his bill to discontinue the duties on tea; and then, when he gave to that measure a resolute opposition. After it became law he took little part in politics. He died May 13, 1846, and was succeeded in the title by his son the present peer.

Lord Ashburton cannot be termed a statesman in the proper acceptation of the term. But he brought to the consideration of political questions a clear calm business-like understanding and considerable experience, and though far from an eloquent speaker, his extensive knowledge and un/questioned probity, as well as his high mercantile standing, caused him in his place as a member of either branch of the legislature to be always listened to with respect. As a public man he will be remembered in connection with the treaty which is usually called by his name. Lord Ashburton was also well known as a liberal patron of arts and artists, not neglecting while forming a valuable collection of pictures by ancient masters to employ living painters, and as one of the trustees of both the National Gallery and British Museum.

ASIA. Of late our knowledge of Asia has been considerably augmented. The Russians have steadily and systematically pursued the exploration of their vast dominions in the north, while the English have continued their surveys and researches in the south and west. The eastern and central portions of Asia alone, particularly the Chinese and Japanese empires, have remained little known; lithotomo inquests have been made by the rapid tides of progress and civilisation which have expanded in every corner of the world. The Euphrates and the Tigris, with the adjoining regions from the Mediterranean to the Persian Gulf, were thoroughly explored and surveyed by the expedition under Colonel Sowerby, and in 1839 and 1840 the practicability of a steam-bond communication with India by that route. In 1836 an expedition was dispatched by the Imperial Academy of Sciences at St. Petersburg, for the purpose of making a trigonometrical survey from the shores of the Caspian Sea to the Black Sea. The object of the enterprise is to ascertain the difference of their comparative levels; a question which had excited great interest for twenty-five years previously. This expedition consisted of Messrs. Fuss, Sahler, and Sawidish, who between two years succeeded in making a most accurate and minute survey of the level of the Caspian Sea, 84 feet below that of the Black Sea. During the years 1834 to 1837 Asia Minor was explored by Calle's, De Teissier, Brant, and W. J. Hamilton, the last of whom has given us a very correct geographical and meteorological view of Asia Minor, and determined the blanks of its eastern coast. In 1836 and 1837 Professor Koch explored the Caucasus, and published the results of his researches in various works, to which a large map was subsequently added.

In 1837 the interesting discovery was made by M. Bouchard and Captain Bézard, that the water of the Aral Caspian Sea was 22 feet lower than in the year 1817. The high water mark of 1837 was 100 fathoms below the level of 1783. This discovery was made accidentally by the officers of the steamer Paris, proceeding from Baku to Tiflis.

But, in the same year, M. Pettenkofer, the distinguished chemist, made an interesting discovery, that a part of the Caspian Sea, particularly the greater part of the eastern basin, is undergoing a process of evaporation which is of great importance to the commerce of the neighbourhood. The Caspian Sea, in common with the other large parts of the Atlantic, has no connection with the ocean, and is therefore not subject to the changes produced by the tides. It is but occasionally that a gale will blow so hard as to produce any perceptible wave, and the wind generally dies down before reaching the considerable depth of the basin. In consequence of this, a heavy current is produced by the difference of temperature, which is great in summer, nearly 80°, and in winter, nearly 100°. This current causes a progressive evaporation of the water, which consequently shrinks, and the part which rises is heavier than the rest, and consequently sinks again. Hence the difference of level is considerable, not from the tides, but from the evaporation of the water. The greater part of the water evaporated, which is very considerable, goes into the sea, which is the reason why the Caspian Sea is not connected with the sea. The water of the Caspian Sea is not salt, but contains only a proportion of salt equal to that of the sea, and is not a part of the sea. The water of the Caspian Sea is not connected with the sea, but is a part of the sea, and is not a part of the sea. The water of the Caspian Sea is not connected with the sea, but is a part of the sea, and is not a part of the sea.
A. odorata, the Woodruff, has its leaves six or eight in a whorl, with perfectly white flowers. It occurs in woods, fens, ditches, and at the side of roads in Europe. It is abundant in some parts of England. The whole plant is remarkable for its fragrance when dried.

A. Gynandrica has it leaves four in a whorl, and flowers of a lilac color. It is found on dry banks and hills in lime

Some of the species, A. armenis and A. taurins, are doubtful natives, but found wild now and then in

ASPIDOPHORUS, a genus of Acanthoperygious Fishes. One species, the A. Europaurus is found on the coasts of England and Scotland. It is known by the names of the Armed Bullhead, the Pogge, the Lyrie, Sea-Foscher, Plank, and Noble. It is a very small fish, seldom exceeding 6 inches in length. (Yarrell, British Fishes).

ASSIGNMENT OF CHATELIS. [HILL OF SALE, S. C.]

ASTERINA, a genus of Star-Fishes, including the smallest of the British species, A. gribonis of Pennyant. The Gibbous Starlet has a 4-sided body, which is thick and covered above and below with short spines; the avenues are bordered by a single row of spines, and the suckers are in two rows. De Blainville makes out of this species two, which he calls A. asterina varia and A. asterina minor. The common is more generally found on the shores of Europe.

ASTRONOMY. [URBANITY.]

ASTROLOGY, a genus of Star-Fishes, remarkable for the branches of the European sea, which are in A. aculeatura, is British. It is however a rare animal; and although occasionally found in other places, is most commonly caught off the Shetlands; hence it is called the Shetland Argos. (Yarrell, British Star-Fishes.)

ASTUR, T. V. G. S.,

ASSUCION, the capital of the department of Assuncion and of the republic of Paraguay, in South America, is situated on the eastern or left bank of the river Paraguay, in 25° 16' South latitude and 54° 47' West longitude. It is the chief town of the Araguai branch of the Pilcomayo. The city, which stands upon a commanding spot, was built in 1553 by a colony of Spaniards under Juan de Salazar; and from the convenience of its situation speedily became a place of some consequence. It was nearly destroyed by fire in 1543, the greater part of the houses being built of wood. From this calamity it speedily recovered; and in 1547 was a place of sufficient importance to be erected into a bishop's see. It contains a cathedral, a college, a hospital, and monasteries. It once contained a college of Jesuits. Properly speaking the town consists of only one street surrounded by several lanes and a great number of houses which stand apart and are surrounded by groves of orange trees. In the center of the town is the public garden, which consists merely of a shop with two or three apartments attached to it. Few of the houses have flat roofs; the greater part are covered with tiles. The best buildings in the city are those mentioned above. The inhabitants are of European and Indian descent with the addition of a few negroes; their number is estimated at 10,000. Assucion carries on a considerable trade in the export of hides, tobacco, sugar, and mate or Paraguay Tea, which is largely used all through South America. Great numbers of horned cattle, horses, mules, asses, sheep, and goats are bred by the farmers, who grow wheat, maize, sugar, tobacco, cotton, mandioic, potatoes, and other vegetables. Honey and wax are produced in abundance; and the rivers supply large quantities of fish.

The air is in and about Assucion is generally temperate and genial; for the greater part of the year the wind blows from the south. The policy of the late Dictator of Paraguay, Dr. Francia, in prohibiting all intercourse with foreigners and with the surrounding states, preserved the republic from the miseries of constant civil and political commotions so characteristic of the neighbouring American republics; but was very detrimental to the prosperity and wealth of the country. By treaties however concluded with the President of Paraguay in March 1853, the subjects of Great Britain, France, Spain, and the United States are free to navigate the rivers of Paraguay, and to settle and trade in any of the towns of the republic. In the dry season vessels drawing 6 feet water and in the wet season vessels drawing 13 feet can sail up to

Asparagin. [Crambe, S. 1.]

Asperula, a genus of plants belonging to the natural order of Paleaceae or Guttiferous. The genus is known by its funnel-shaped corolla, and by the fruit being dry and not covered by the limb of the calyx.
As a cove, above which the river Panguey is navigable for vessels of considerable size for 600 miles.

A THAMANTINE. [CHEMISTRY. S. 2.]

ATPROINE. [CHEMISTRY. S. 2.]

ATTACHMENT OF DEBTS. A creditor who has recovered judgment against his debtor, may now, on obtaining a separate judgment against the other by the assistance of a sheriff or by a judgment debtor by third parties; then either by a summary application to a judge at chambers, or where the debt is disputed by the garnishee (the person in whose hands the attachment does not reside), by proceedings in any other action, enforce payment of these debts to himself, in discharge of his own claim; such payment operating as a discharge to the debtor. ('Common Law Procedure Act, 1854'.

AUCKLAND, [NEW ZEALAND. NEW.]

24DE EDEN, 2nd LORD AND 1st EARL OF, eldest surviving son of the 1st lord, was born in 1781. After receiving his education at Eton and Oxford, he entered the House of Commons as M.P. for Woodstock, but was soon removed to the House of Lords by his father's death. He formed a part of the Whig administration as President of the Board of Trade, and was appointed First Lord of the Admiralty by Lord Melbourne in 1834. In the following year he went out to India as governor-general. His administration was followed by the Act of Union with the Ath the affairs of the Empire (1858-63). The Earl of Auckland was recalled to England in 1849, having been previously advanced to an earldom; the final settlement of the Afghan affair was left for his successor, the Earl of Ellenborough.

Lord Auckland died soon after his return from India.

AUCKLAND ISLANDS, named after Lord Auckland, lie in 51° 8' S. lat., 166° E. long., about 900 miles S.E. from Van Diemen's Land, and 180 miles S. from New Zealand.
The group, which was discovered in 1806 by Captain Briscoe, consists of one large island and several smaller islets. Auckland, the largest of the group, is about 30 miles long and 15 miles broad, and contains about 100,000 acres. The entire group is of volcanic formation, composed of greenstone and basalt, and is covered with forest growth of luxuriant vegetation.

The eastern coast contains two principal harbours, formed by inlets of the sea, which reach to within two or three miles of the western coast, and are only six miles from each other. The coast is covered with forest growth of luxuriant vegetation.

The climate has been described by Sir James Ross, Captain Briscoe, and other navigators who have visited the islands, as mild, temperate, and salubrious. The temperature in the valleys is scarcely ever lower than 35°, or higher in summer than 70°. The weather is generally good, but there are occasional high winds and heavy rains. Auckland Island is abundantly supplied with small streams. The soil is very fertile, and the hills, except a few of the highest, are thickly covered with large trees. The elevated ground is covered with moss and a kind of tall grass. Dr. Hooker notices the Auckland Islands as remarkable for the variety of their vegetable productions, eighty flowering plants having been collected; and of these, forty only, are commonly found in other parts of the globe. Several animals have been noticed for their beauty and novelty. The only animals found on the island are goats and rabbits. Pigs were left on Auckland Island in 1807 by Captain Briscoe, on his return from his second voyage, but they have disappeared, with the exception of the goats, a few of which are now kept for the use of the inhabitants. In the woods three or four species of small singing-birds were found. On the heights petrels breed in considerable numbers. Hawks, gray ducks, snipes, coromorants, and the common shag also inhabit the islands. Fish are plentiful in the coast of Auckland Island, and the rocks are covered with limpets; while the whale fishing carried on in the neighbouring seas may yet become very valuable. Sir James Ross mentions that while he was in Laurie Harbour many sperm-whales came into the anchorage.

The Auckland Islands were granted by government to the Messrs. Enderby on advantageous terms, in consideration of the services rendered by their father to this country, as also many other services which he rendered to the commerce of the south seas, by Captain Briscoe whilst in the employ of the Messrs. Enderby.

A company to which the Messrs. Enderby ceded their privileges, obtained a charter of incorporation on the 16th of January, 1849, for the purpose of prosecuting the whale fishery.

In 1849 the South Western Whale Fishery Company was chosen as the head station of the company, from the superior facilities it affords to whaling vessels. The islands were uninhabited until the Southern Whale Fishery Company, under the conduct of one of the Messrs. Enderby, made a settlement there in 1849.

AUDOUIN, JEAN VICTOR, was born at Paris on the 27th of April, 1797. His early education was intended to fit him for the law, but his inclinations were towards the study of organic nature, and he soon devoted himself to the study of medicine. His mind was early directed to the study of the natural history of insects.

In 1817 he published a work on the anatomy of the Insects, and especially those on the Annelida, introduced him to the notice of Cuvier, Geoffroy St. Hilaire, and Latreille, with whom he lived on terms of intimacy, and from whose instruction he obtained the enlarged views of the natural history which so strongly interested him. The results of most of his investigations were published in the form of contributions to the various journals or in the Transactions of societies. These papers were numerous, and they are all valuable.
for the study of the habits and the structure of insects. In all his more important works on entomology, it is evident that he did not regard insects as the end of his inquiries, but that he looked upon them as a great class of phenomena, illustrating the general laws that were deducible from the study of the whole animal kingdom. With his external forms were only regarded as dependent on an internal structure, which it its into a leigated form, essentially related to the whole animal kingdom. It was thus that he was led to investigate the annulus subordinate kingdom of animals, and succeeded in adding to science so many important facts which assist in indicating the true relations of the animals to one or other the other division of the animal kingdom.

(Abridged from the Biographical Dictionary of the Society for the Diffusion of Useful Knowledge.)

AUDUBON, JOHN JAMES, an eminent American naturalist, was born in Louisiana, in the United States, on the 4th of May, 1780. Both his parents were French. His father, who was an ardent admirer of the beauties of external nature, endeavored from his earliest years to foster in him a similar taste, and especially directed his attention to the many tribes of birds which inhabited that part of the state in which they resided. The boy's passion for the study of birds and everything connected with them, soon outran his father's promptings. While still a child he obtained possession of the early manuscripts and engravings of the American birds, and cherished them as his choicest treasures. At this period, when any of his birds died, his chief regret was that he could no longer, either himself retain what had been so bright, or convey to others a notion of the departed beauty. In 1800, having placed under his eyes a book of ornithological illustrations, the boy determined to become a draughtsman himself. Feeling his deficiency in the elements of drawing, he applied himself with great assiduity to acquire the ability to draw well. At length he made his way to Philadelphia, where his father took him to Paris, and placed him in the studio of the celebrated David. Here, though he neglected the study of the higher principles of art, he became a skilful draughtsman; and at the recommendation of his teacher, who showed his list, he set forth to Paris, where he was given the title of the famous master; and, at the age of seventeen, returned to the 'Birds of America.'

In 1798 his father gave him a farm in Pennsylvania, near the river Schuykill, but he sadly neglected his agricultural duties. Of his occupations here, he says, "my rambles invariably commenced at break of day, and to return wet with dew and bearing a feathered prize, was, and ever will be, the highest enjoyment for which I have been fitted." The farm, moreover, was unprofitable; and his father, a married young lady, who shared his after honours. For nearly twenty years he now pursued commerce (nominally) and his success was what may be easily supposed. He removed to the westward, and thence to London, and finally to France, where his example excited still more a zeal that needed no spur. In 1810 he sailed forth on a great exploring expedition, and sailed down the Ohio with his wife and child, bird-sketching as he went. In the next year he explored Florida. Finding the joint pursuit of business and science impossible for him, he left at length abandoned his nominal business altogether.

On the 5th of April 1824, he visited Philadelphia, where Dr. Mease, his only intimate friend in the place, introduced him to Charles Lucien Bonaparte, prince de Moustagan, bulle, brother of the Emperor Napoleon, who published a splendid continuation of "Wilson's Ornithology." The prince warmly encouraged him in his plans, and he now began seriously to contemplate publication. From Philadelphia he went to New York; and thence, taking the Hudson for his high-road, penetrated into the pathless woods. It was now he projected, in a methodical manner, his famous publication of illustrations, which he divided into numbers, to each number five plates, according to the arrangement given of the dimensions of nature; and very often they are presented also in the most capricious attitudes, but with the strictest fidelity to nature.

After a ramble of eighteen months, he returned to his family, and passed all the surrounding forests, and then sailed to Europe. Without the means of publishing his great work, the third part of which, when it appeared, cost 40l. per copy to the purchaser, he landed at Liverpool in 1826. His letters of introduction procured him a cordial, and even enthusiastic, reception in that town, in Manchester, and in Edinburgh, where he commenced the publication of his illustrations and descriptions of the 'Birds of America.' The work, however, was quickly referred to the hands of London artists. In September 1828, he once more visited France, where he was rapturously welcomed by the scientific world. Baron Cuvier pronounced a panegyric of him before the Institute. Charles X., Louis Philippe, and the Duchesses of Orleans were present. Mr. Humboldt, the Institute, and others, joined his subscription list. By the 25th of November 1828, the eleventh number of the work, and 100 plates, had appeared.

He now devoted himself for the purpose of refreshing some of his drawings, and of bringing his wife back with him to Europe. On the 1st of April he set sail, and in about a year he returned with Mrs. Audubon. Having again gone back with his wife to America in August 1831, he proceeded to Florida, explored the forests of Mammaw, made a voyage to the Gulf of the St. Lawrence and the coast of Labrador, and visited Newfoundland and Nova Scotia. On the 28th of April 1833 he held at New York, where now the greatest honour was paid to him, an exhibition of his illustrations of American water-birds. In 1834 he again went to Florida, and thence to Texas. The scientific fruits of Audubon's romantic rambles had procured him many tokens of respect. He became a Fellow of the Royal Society of Edinburgh; a member of the Board of Natural History at New York; of the Natural History Society at Paris; of the Wernerian Society of Edinburgh; honorary member of the Society of Natural History at Manchester, of the Royal Scottish Academy of Painting, Sculpture, and Architecture, and other important associations. Audubon's book was the largest and grandest which had been published on Ornithology. Every sort of bird is engraved, male, female, and young. The drawings are admirable; and the descriptions are second in merit to the drawings. The life of exploration and study was prolonged to the ripe age of 71. He died on the 27th of January 1838, at Minniesland, near the city of New York.

AUSTRALIA, AUSTRALIA, of the 'Penny Cyclopaedia,' a brief narrative has been given of the successive discoveries of the various exterior portions of the continent, and also of the most important surveys of the coasts. The principal journeys of exploration of the interior which have been thus been made were conducted by Dr. Grey, Cunningham, Oxley, and Stuart, and the information acquired is embodied in the article above-mentioned.

Further Progress of Discovery. Captain Sturt, in 1828, had discovered the river Darling, and traced it downwards about 30° S. lat. In 1829, he abandoned it. At the end of 1829 Captain Sturt was again sent into the interior, to trace the farther course of the rivers. He proceeded to the south of Sydney, and intersecting the course of the Lachlan, he discovered the Murumbidgee. In 1835, traced the Darling from the point where Sturt had left it in 1828 down to 23° 30' S. lat. In 1836 Sir Thomas Mitchell followed the course of the Lachlan downwards, and crossing from that river to the Murumbidgee, from it gained the banks of the Murray, and, following its course, reached the Darling at its confluence with the Murray.

In 1837-38-39, Captain George Grey conducted two expeditions in north-west and western Australia, and made some important discoveries in Western Australia between Cape Currie and the Swan River, about 32° S. lat.

In 1838 Captain Sturt led an exploring party overland from New South Wales along the banks of the Murray. He commenced his journey at the ford where the Hume intersects the road to Port Phillip, and in so doing crossed the whole of the waters of the south-east angle of the Australian continent.

In 1839 Mr. Eyre fitted out an expedition, and tried to penetrate northwards into the interior, but having descended Mount Arden, on the western side of the range, within about 20 miles of the coast, he was driven back by the severe storm, and returned to the same point. He therefore went to Port Lincoln, whence he proceeded along the line of the coast south to Fowler's Bay, the western limit of the colony of South Australia. He then returned to the coast, and pushed boldly forward to the N.E. for Mount Arden, more to the south of the range, but was unable to advance farther than 30° 30'.

In 1840 Mr. Eyre again conducted another expedition towards the central part of the continent. He was unable to penetrate to the north, but steadily advancing westward,
after a journey of excessive difficulty and privation, established the startling fact that there is not a single watercourse on the whole coast from the mouth of the Albert River, Aug. 30, 1843, to the mouth of the Albert, Aug. 29, 1845, a distance of more than 1,500 miles.

Whilst these attempts were being made to penetrate to the interior from the coast, a naval expedition was actively engaged on the northern coast.

In command of the Beagle, he carried on a survey of the intertropical shores of the continent, which led to the discovery of two considerable rivers—the Victoria, in 14° 50' S. lat., and the Albert, in 17° 20' S. lat., 139° 54' E. long. Captain Stokes succeeded Captain Wickham in the command of the Beagle, and penetrating nearer to the north than had been done before.

Captain Sturt, in his last journey, left Adelaide on the 13th of August, 1843, and followed the course of the Murray as far as its confluence with the Darling, then struck northwards. Crossing vast tracts of barren ground and the great stony desert, on the 6th of September, 1845, he reached 24° 30' S. lat., 136° E. long. He arrived at Adelaide on his return, Jan. 19, 1846.

Sir Thomas Mitchell spent the year 1846 in an exploring journey into the interior of tropical Australia, making his way immediately to the westward of the mountain range which borders the southern coast of Moreton Bay. He had to pass over a great deal of dry and barren land, but he also discovered a large extent of singularly beautiful and rich country, especially about the head of a river which he discovered near 29° S. lat., and which he named the Victoria. It tended to the north-west, but it was left of the expedition, after the return of the expedition, was despatched to continue the search along its banks. He found that the Victoria, called by the natives the Barcoo, soon turned to the south-west, toward the interior. He followed it for about 100 miles beyond the point where he left it was left behind, and from the quarters of the expedition in 1844, 1845, and 1846. In this last and fatal journey, he search of the country around, he found a country of remarkable beauty and fertility—a discovery which he, with characteristic ardour, returned 300 miles to the nearest frontier station. The richness of this part of Australia is therefore well established, and although the frequent failure of the streams is at present a complete bar to any successful squating settlements, little appears to be wanting for the development of its resources besides the construction of dams, by which the channels of many of the streams might be at once converted into canals for the reservation of the water, and of reservoirs, for which the undulations of the land afford peculiar facilities.

Dr. Leichardt started on his overland expedition from Moreton Bay to the north coast, at the end of September, 1844, and returned to England on the 24th of February, 1845. In this journey Dr. Leichardt crossed a large extent of beautiful and fertile country. At the end of 1846 he started on a still more difficult and perilous journey, from the eastern coast to the western, across or on the skirts of the great desert. This journey was undertaken in 1844, 1845, and 1846. In this last and fatal journey, he was accompanied by Mr. Lynd, whose name has been given to one of the rivers on the north coast. Dr. Leichardt has not since been heard of, and there seems to be hardly a doubt that he and all his party have perished in the great central desert.

The latest expedition to the interior of Australia was that of Mr. A. C. Gregory, from the north coast, which was organised at Moreton Bay, and proceeded by sea to the mouth of the Victoria River. The horses were landed at Point Piers, in September, 1846. On the 9th of May, 1846, the party was employed in preliminary details, and in the exploration of the country to the south of the Victoria River, having penetrated the interior deserts to 18° 20' S. lat., 127° 30' E. long. On the 21st of June Mr. Gregory left the encampment on the coast, accompanied by Mr. Stirling. The rapid progress of the country compelled them to increase the latitude to 15° S., after which they kept parallel to the coast as far inland as water could be found in the rivers, the greatest difficulty of which is the scarcity of rain in the sea, not exceeding 100 miles. Proceeding north-east from the mouth of the Albert River, for 10° or 12° S. lat. and 18° 20' S. lat., when the Gilbert River entered the mouth of the sea, the second hop was left. Crossing the head-waters of the Lynd in 18° 40' they reached the Burdekin, Oct. 18. Their route was then along the right bank of that river to the junction of the Suttor River, which was followed up to the Beylando. Tracing the course of the Suttor River, they arrived at the mouth of the Ybar River, which was the mouth of the river which runs to the junction of the Comet and Mackenzie Rivers, whence their course to the Dawson brought them, on the 22nd of November, to the farthest station of the settlers, whence they proceeded to Brisbane.

The Australian Alps, which occupy the south-eastern angle of the Australian continent, rise to an elevation of 7000 feet above the sea, and their summits are perpetually covered with snow. In the rest of the mountain-range which flanks the eastern coast, the loftiest summits seldom exceed the elevation of 4000 feet, though there are some which rise to 6000 feet.

North of 33° S. lat. the principal valleys are transverse, and the course of the rivers is consequently west and east. The rivers flow to the north to the sea, while the streams flowing in the opposite direction are declining, however, considerably towards the south. Its entire length from its source in the Liverpool range is above 300 miles. It is navigable for small vessels up to Morpeth, about 56 miles from its mouth. Its two principal tributaries, the Warrego and the Boggo, which run along the eastern side of it, are navigable for a somewhat greater distance. At the mouth of the Hunter is the town of Newcastle, the chief shipping-town of the Hunter coal district. In the vicinity are extensive coalfields, the largest under the name of Cumnor, which is worked by the Barby Brothers. Much of the coal from the Barby Brothers, and other South Australian mines is smelted here. Up the Hunter the land is much more fertile than along the coast, and the towns of East and West Maitland and Morpeth are the centres of extensive coalfields. The town of Morpeth is on the north of the Hunter, and the Hastings, which falls into Macquarie Bay, still farther north, also runs nearly east and west: neither exceeds 100 miles in length. Port Stephens, about 20 miles north of the Hunter, is a bar bour, but convenient for small coasting vessels, and the outlet of the produce of the Australian Agricultural Company, a part of whose extensive territory stretches along its northern bank, and for a considerable distance up the river Karah, of which Port Stephens is the mouth. The Hastings forms the small harbour of Port Macquarie.

North of Port Macquarie the country changes greatly in character. The mountains are very lofty, some of them attaining an altitude of 6000 feet, while the formations are often of great richness and fertility. The country is rich in coal, and among them the Bellengem, the Clarence, the Richmond, and the Tweed, are navigable for coasting vessels. The vegetation is more luxuriant, assuming more and more of a tropical character as we proceed northward. The timber is of a larger and more useful character. Moreton Bay, especially is characterised by its pines, of which the finest are the Moreton Bay Pines (Aroracius Crandallii) and the Bunya Bunya (A. Sedgelli). The cedar is also great repute for the beauty of their wood, and the chestnuts are much valued. Cotton, coffee, sugar, and tobacco grow vigorously in this part of Australia; except tobacco, however, they are little cultivated, in consequence of the impossibility of obtaining labourers. Moreton Bay is a fine harbour, 60 miles long from north to south by from 3 to 20 miles wide. The islands Moreton and Stradbroke stretch across its mouth, leaving on the south merely a narrow passage navigable only by boats, but on the north there is an entrance sufficiently wide and deep for ships of the largest size. Between the islands lies a dangerous sand-bar. The navigable route to Brisbane and Logan, with several smaller streams, fall into the bay. The Brisbane is a large and important river, having its fairest source in the coast range near 15° 30' E. of its mouth, and its course is towards the east. It is navigable by vessels drawing 16 feet of water 20 miles from its mouth, where the ship navigation is stopped by a rocky shoal, but boats ascend 40 miles higher. The Moreton Bay district and the country northward appear to be free from the drengths which are so destructive in the southern parts of the country.
North of Moreton Bay the mountains recede to the west, and about 20° S. lat., become much lower, losing in fact, in a gradual transition, into an extensive plain of sandstone or limestone. They are mostly barren, but at some distance near the Blackwood River, which falls into the sea at the western angle of Flinders Bay, Mr. Ross found considerable forests of timber-trees fit for naval purposes; he also discovered good gardens of melons, cucumbers, &c., and the interior are sandy deserts. Swan River has a bar at its mouth, but within it is navigable for some distance. The bed of the river rises rapidly from its mouth, and some distance inland the channel is frequently dry. Perth, the capital of Western Australia, is built at the mouth of Swan River.

Along the north-western coast the country differs considerably from any part of the continent hitherto described. The mouth of the Swan River is distant from the coast about 100 miles; the coast is studded with high headlands, some of which are 800 to 1000 feet high. Numerous islands, some of them basaltic, line the coast, and the scenery is wild and striking. Mounts Trafalgar and Waterloo rise to the height of 800 feet, and Mounts Greville, 140 miles to the north, are the highest. The coast as far as Cambridge Gulf, are low hills. At Cambridge Gulf a river of some importance falls into the sea. It was named the Victoria by its discoverer, Captain Stokes, R.N., who landed on the west side of the mouth of the river, which he called the Fitzroy Range. In its lower course the Victoria flows through low, sandy, mangrove flats, which at its mouth have been cut into numerous islands, covered during floods; but higher up, its banks are hilly and very fertile. The Fitzroy Range rises in one or two ranges to the height of 840 feet. From the Mosquito Flats a connected range, from 700 to 800 feet high, runs off to the north-east. Stretching away from the river towards the interior Captain Stokes saw apparently impassable ranges. North-east from the Victoria and the Fitzmaurice rivers is the Macdonald range, which consists of hills averaging from 400 to 600 feet in height. Near the shore, between Cambridge Gulf and the Gulf of Carpentaria, these hills become lower, and terminate generally in sandstone cliffs, seldom exceeding 50 feet in height. But about Malivare Bay granite occurs. At Coburg Peninsula, where was the now abandoned colony of Port Essington and the town of Victoria, the cliffs are of red sandstone; the interior of the coast, which is broken by low hills, consists of a continuous forest.

The shores of the great Gulf of Carpentaria are almost invariably low and flat, and generally covered with mangroves, with bushes or sand, are seldom more than from 10 to 30 feet above the level of the sea. On the eastern sides there are more small trees, but the shore is one wide, low, level, sandy waste. The rivers which fall into the gulf are few and unimportant. One or two inlets which appear to be the mouths of rivers, have indeed not hitherto been explored, but there is nothing to lead to the belief that they differ from those which have been followed up. The chief of the rivers in the Gulf of Carpentaria is the Flinders and the Albert, but like the others they consist merely of short and narrow streams opening into wide shallow estuaries. The Albert was ascended by its discoverer, Captain Stokes, in a boat for about 50 miles from its mouth. He found it bordered by open woodlands of casuarinas and gum-trees. West of this, to Strezlecky Bay, is a mountainous tract, known as Gawler’s Range, the summits of which increase in height towards the west, where they attain an elevation of 2000 feet. West of Strezlecky Bay, and extending into Western Australia, is a waste and dreary country, covered merely with scrub.

The whole of the western end of the continent is included in Western Australia. The coast from Port Lincoln to King George’s Sound forms the Great Australian Bight, and presents no remarkable appearance; from Strelitz Bay to Cape Arid, about 1000 miles, there is an unbroken line of cliffs from 300 to 600 feet high. The interior here, as far as it has been explored, consists of apparently interminable plains: no river is visible and no fresh water procurable. Imagine a waste, of blue hills. King George’s Sound, at the mouth of which is the town of Albany, the country improves considerably. The surface is much broken, and there are lofty hills and rapid streams. From the southern part of the Great Australian Plain, called the Great Western or Australian Mountains, which terminates there in Point D’Entrecasteaux and Cape Leeuwin, runs northward as far as Shark Bay, at a distance of from 50 to 100 miles from the coast, and rising from 500 to 3000 feet above the sea. Portions of these connected mountains are known as the Gairdner’s, Morebey’s, Herschel, and Victoria ranges. The highest summit, Tumbarine, is said to attain an elevation of 5000 feet. The coastal districts are said to be fertile, and to produce sandstone or limestone. They are mostly barren, but at some distance near the Blackwood River, which falls into the sea at the western angle of Flinders Bay, Mr. Ross found considerable forests of timber-trees fit for naval purposes; he also discovered good gardens of melons, cucumbers, &c., and the interior are sandy deserts. Swan River has a bar at its mouth, but within it is navigable for some distance. The bed of the river rises rapidly from its mouth, and some distance inland the channel is frequently dry. Perth, the capital of Western Australia, is built at the mouth of Swan River.

The sheep of this country are of the finest quality. The wool is long and fine, and is said to be especially adapted for the manufacture of hessian. The hides are said to be of the finest quality, and to yield leather of a superior kind.
of drift sand sometimes 100 feet high, running in parallel lines as far as the sight could reach. The dryness and the heat of the day made the appearance of this plain, near 26° 33' S. lat., 139° 30' E. long., was a memorable story and quite sterile desert, which extended, as far as he could ascertain, about 80 miles in length and 35 miles in width. Near 27° 33' S. lat. Captain Sturt discovered a sheet of water which he called the Snowy Creek. The stream flowed for nearly 80 miles, and ending on each side in arid sands. It has been supposed that this creek may be in seasons of flood connected with the singular horse-shoe shaped depression known as Lake Torrens, which as already mentioned in my last number, was discovered by the mountainous head of Spencer's Gulf, and that on the other side it might unite with Sturt's Stony Desert. Lake Torrens, it may be as well to mention, though called a lake, is not filled with water, but is merely an extensive marshland, and most of it is possessed of occasional unconnected pools and muddy holes. In seasons of great floods it would no doubt be filled with water, which is possible may find an outlet in Spencer's Gulf. In a country where rain was abundant Lake Torrens would of course be a permanent lake, according to the ordinary occupation of that term. Generally it may be said of the continent, that the ranges of mountains mentioned as stretching along the south-eastern and eastern coasts, in some places to a height of 3000 feet, and in others along a level wide, fertile, and thinly wooded plains, with occasional sandy tracts, to extend between them and the sea. Towards the interior, beyond and nearly parallel with the mountain ranges, are undulating downs of more or less stony character, and as far as the Darling Downs, discovered by Mr. Cunningham, the Fitzroy Downs discovered by Sir T. Mitchell, the Goulburn, Bathurst, Manero or Brisbane Downs, and the New England districts, with vast fertile plains, lying along and between the great rivers. These downs afford the chief sheep runs, the plains the cattle pastures. Farther inland are wide-spread marshes and worthless jungle, and enormous barren, arid, and sandy, or stony deserts wholly uninhabitable, and which have hitherto baffled the attempts of man to explore them. They have not been found; the densest are those which occur in the Moreton Bay district and in tropical Australia. The trees are almost invariably light of foliage and very marked in character. The herbage is thin; the grasses are nutritious, but generally grow in detached clumps.

The river system of Australia, as far as is known, is peculiar. Many of the rivers of the interior are lost in the sands, others are subject to immense overflows so as to convert in the wet season a large portion of the adjacent country into vast swamps. By means of these the sands are carried places quite dry and they are converted into a number of scarcely connected lagoons. Few of the rivers which fall into the sea are navigable, and nearly all have bars or other obstructions which prevent their use.

The Murray is an exception to the other known streams of the Australian continent. The basins of this fine river are in the deepest recesses of the Australian Alps. The headwaters of its immediate tributaries extend from the 38th to the 32nd parallel of latitude, and from 146° to 148° of longitude. It reaches the lowlands near 36° S. lat., 147° E. long., not far from the rising town of Albury. Its course from this place is exceedingly tortuous, the curvatures being short, abrupt, and very numerous. The whole of the upper course is obstructed by sand shoals, and snags formed by trunks of trees, and other objects which have caught in the bed of the stream; but there appears to be no insuperable obstacle to the clearance of the channel if there were sufficient intercourse to render it profitable. It would be a costly and tedious process, and useless also unless an embargo was formed, as their river is subject to annual overflows, when the country for a considerable space on both sides is converted into a swamp. These floods prevent agricultural operations being carried on, and the banks of the Murray above the junction of the Murray and the Murrumbidgee attempts have been made to raise wheat on the sandy heights, but they have not been successful. On its left bank the Murray receives in this part of its course, the Lachlan, the Goulburn, the Campaspe, and several other streams; on its right is the vast impassable tract known as Murrumbidgee, which lies between the Murray and the Murrumbidgee rivers. No river here falls into the Murray on the right bank, but there are numerous creeks which pass from the Murray to the Edward River, which is a great arm of the Murray which runs between the main stream and the Murrumbidgee for many miles, and receives near its eastern end the Billibong River. A large part of the drainage of the Murray and the Murrumbidgee is a swamp; much of the remainder is cut up by the Edward, and the many connected channels, and the innumerable lagoons, or biddlesong as they are called by settlers. Many of these lagoons have on the top a thick growth of sedges, and in the valleys, and along the edge of the flood, and in the mineral. The soil is generally a grey clay. The Murray receives the Murrumbidgee in about 143° E. long. The river is here about 350 feet broad, from 12 to 30 feet deep. The banks are at the rate of 40 feet above the flood of 143° E long. it is joined also on the right bank by the Darling, which is here 100 yards wide and rather more than 12 feet deep. As far as the junction of the Darling the Murray continues to flow to the west-north-west, but afterwards it passes between some lime stone cliffs and its course is west to the west, and the river is considerably increased in size. After passing the meridian 140° it trends to the south; and in this direction it flows without receiving any tributary of consequence till it expands at its mouth into the Lake Victoria, which is 60 miles long and 40 miles broad, but generally very shallow. The water of the lake is brackish and it communicates with the sea at Encounter Bay by a passage impracticable even for boats. The river Murray extends into the sea to a distance of about 50 miles from the head of the lake 350 yards broad and from 20 to 30 feet deep. It appears certain indeed that it is navigable for steamers of light draught up to its junction with the Darling; and recent explorations have shown that it is capable of carrying the heaviest goods at the mouth. The course of its windings, the length of the Murray is probably not less than from 1300 to 1500 miles. Little influenced by the sudden floods to which the other Australian rivers are subject, its rise and fall are equally gradual. Instead of stopping short in its course, as they do, its falling or terminating in a marsh or exhausting itself over extensive plains, its never-failing fountains have given it strength to cleave a channel through the interior desert, and carry its broad and tranquil waters to the sea.

The Murray receives the first addition to its waters from the eastward in the month of July, and rises at the rate of an inch a day till December, in which month it attains a height of about seventeen feet above its lowest or winter level. As it grows it fills in succession all its lateral creeks and lagoons, and ultimately lays many of its flats under water. As it rises, so it falls, gradually. No river falls into the Murray after its confluence with the Darling, nor does any fall into the Darling from the west after it reaches the low lands of the salt range. The rains that are in the Japanese months, when the Murray rises, the Murray collects several overflowings which are fed by the northern rivers, the Murrumbidgee, and other interior streams. Geochemistry and Mineralogy are essential to an understanding of the level of the Murray. The Murray is the only large river in Australia, which the Murray and the Darling in the east and west. Granite forms the axes of the ranges of mountains described as occupying the south-eastern and eastern portions of the island, having frequent masses of metamorphic rocks in connection with it. Much of the granite is in the form of small rounded masses, in the interior, the felspar and hornblende so largely abound as to modify the granite type; in some places the hornblende predominates, and frequently, as between Armiprior and Braidwood, the granite passes into sienite and porphyry. Examples of all these varieties are met with in the Australian Alps, about
the sources of the Murray, in Moneroo, in the Carrumbenya Range, the Araluen and the Main ranges, Mount Victoria, and many other localities. The rock formation is extremely\nvery widely, and vary as usual very much in their\ngneissic structure. Very commonly they consist of basalt,\ngneiss, and various amygdaoids, and have an overlying\ndeposit of conglomerate grit and sandstone. The trappean\nregion of Maneroo, which may be taken as illustrative\nand Hammerton (1862) occupied a trough\nbetween granite mountains (here the Snowy and the Coast\nmountains), which it has filled up, sending its streams of\nsmaqueous lava to considerable distances on each side of\nthe general line of the axis of eruption. In Maneroo this\naxis has a north-west and south-east direction, and ranges\nfrom the head of the Tawomba towards the principal head\nof the Murrambiggee, at the northern extremity of the\nSnowy Mountains, or Australian Alps. Connected with this\ngeneral trend of the trappean rock, which has produced\nthe plateau or plains," as bare tracts occupied by basalt, &c.,\nare improperly locally designated, are various outlying hill\nand ranges, insulating patches of the schistose rocks, or\npeering and transmitting the larger masses of that system.

But the discovery and exploration of the Australian\nagency, their texture, structure, and composition, prove\nthem to have a common relation with each other, and with\nthe great development which has occasioned the remarkable\ncontrast of the mountains ranges to the north and South\nCoast ranges to the east, and the constant marked anti-
clinal division between the waters flowing on the northern\nside to the Murrambiggee, and on the southern to the Snowy\nRiver. It is to the trappean outburst, which is undoubtedly\nconnected with the discovery of the Snowy and Coast ranges,\nthe condition of the present surface of the counties of Beresford,\nWallace, and Wellesley is in a considerable measure due;\nit has directed the principal drainage of the country in two\nopposite courses, and has produced innumerable physical\ndisturbances of great extent.

A large portion of the basin of the Murrambiggee is\noccupied by quartz phrynyte, which is also largely developed\nin many other places. Porphyritic and basaltic dykes are\nvery frequent. Very fine examples of columnar basalt occur\nat Cooma and elsewhere, and the rock of the``Merbein``\nand the``Burowra`` are porphyritic and basaltic dykes in\nunmarkedly in other parts of the great mountain district.

Serpenite, soapstone, pitchstone, and a fine red jasper are\nfreely met with in the trappean districts. Laminated,\ncoaled, and coaled and conversed, as the term is used\nin the coal regions, occur in several places. In the\ngrid of the gullies running into the Boshell\nhaven, a little below Glenrock, the limestone is seen passing\nto statuary marble, white and crystalline; black marble\noccur in strata in Bourough Creek. A bed of limestone,\nwhich contains small quantities of fossil shells, has been\nfound in the north and south of Bathurst, has been termned carboneous. The coal and associated bed of sandstone and shell, which occur\nextensively on the eastern coast from Port Stephens to\nBotany Bay, occasionally ranging into the interior, have\nbeen considered equivalent to the coal-measures of Europe,\nmerely from their mineralogical characters. What the age\nof this Australian coal deposit may be we have no means of\naccurate judging; but it is worthy of remark, that a fossil\nplant (Glossopteris Browni) detected in it is also found\ndiscovered in the Damara coal district in India. The coal\nitsell appears to be abundant and generally of good quality.

Coal also occurs in great quantities on the Warrumbung\nand elsewhere in the mountain district of New South Wales. Mr. Roe in 1844 discovered coal by the south of the\nFitzgerald River, about 149° 40′ E. long., 34° 10′ S. lat., and by the Phillips River some distance to the west, both places being in or near to Dungeness Island and easy of access. It has also been met with in several other places.

Sandstone rocks extend very generally through the mountain district. Sydney is built upon a sandstone deposit, which\nextends as far inland as Mount Victoria, and forms the bulk of the river valley. The city of Sydney is built largely upon\nthe sandstone.

The sandstones are of various kinds, fossiliferous, ferruginous,\nsilicated, argillaceous, and calcareous. In parts they appear\nvery similar to those of the old red sandstone formation of\nEngland. Found in conjunction with fossiliferous lime-\nstones and conglomerates they closely resemble those of the

Devonian system. Both the limestones and sandstones are of\nexceeding value for economical purposes. Sandstone and\nlimestone rock are extensively in use for building stone,\nfrom the shores of Western Australia. In North Australia is a great sandstone plateau rising 1800 feet above the level of the sea.

The slate and other schistose rocks are numerous and\nimportant. A quartziferous schist is the predominant rock of the country between the Gumban Plateau and the\nGreat Valley, and it prevails extensively throughout New South\nWales and the eastern part of Victoria. The soil which\ncovers this rock is generally poor, but the rock itself is rich\nin mineral resources. The slates are commonly gray, bluish, or\nyellowish; goethite occurring as streaks and film-like veins.\nThe slates are not uncommonly intersected by veins of\nquartz and tourmaline. Gray or brownish-white, soft or hard,\nfusible beds of schist occur in conjunction with the slates,\npassing into the true slate or sandstone, and becoming occasion-
ally very quartzose, bands of quartz and transparent\nfibrous veins of quartz traversing them. Clay-slates and\nother argillaceous deposits are also general. The clays and\nother tertiary deposits occupy a wide area; in fact, it is\nprobable that the whole of the area is formed of horizontal\ntertiary deposits, broken here and there by hilly tracts\nrising out from them, like islands from the bed of an inland\nsea. Good brick and pottery clay is found.

Australia was not until lately considered rich in minerals.\nThe first discovery of minerals in Australia was in 1845, and still more the extraordinary discoveries of gold in 1851, however led to investigations which have gone far to\nshow that Australia is mineralogically one of the richest\nregions of the world. The first official mention of gold\nbeing discovered in Australia was in an official letter from the\nSecretary of State from Sir George Gipps, lieutenant-governor of\nNew South Wales, dated 2nd of September, 1840, in which is\ncorded a report from Count Strehlecki, stating that he had\nderived the information from a grazier named Caddy, who had\ndiscovered in a small quantity of gold in an "auriferous sulphuret of iron, partly decomposed." No further notice was taken of this communication. Sir R. I. Murchison, however, in the course of various state-
ments respecting the Ural Mountains, which he read to the\nGeological Society of Dublin, in 1841, and in his geological\nand 1842, called the attention of men of science to the fact of the similarity of the formation of the Australian to those of the Ural Mountains, and asserted his belief that gold\nmust exist in Australia. No steps were taken to pursue the\ninquirу practically, and Sir Robert Banks, in a letter to the Geological Society of Cornwal, urging unem-
ployed Cornish miners to emigrate and search for gold in the\ndrift and debris of the Australian Alps. In 1848 Sir Roderic\nand Great Britain, addressed a similar letter to the Geological Society of France for the Colonies, stating his reasons for believing that gold\nwould be found in Australia in large quantities, but no notice\nwas taken of his communication. Meanwhile efforts had\nbeen made to attract attention to the subject in Australia.\nSir Charles Sturt, who had been sent to the west coast of New\nS. W. in April, 1851, when Mr. Hargraves, who had returned from gold-seeking in California, wrote to Governor Fitzroy, an-
nouncing that he had been seeking for and had found gold,\nand offering to discover the locality for a certain reward;\nand somewhat later Mr. Lancefield forwarded a specimen weigh-
ing 34 ounces, which he had found in the river Turon, near its\njunction with the Macquarie, with a similar proposal. Sir Charles Sturt, who had been sent to the west coast of New\nS. W. in April, 1851, when Mr. Hargraves, who had returned from gold-seeking in California, wrote to Governor Fitzroy, an-
nouncing that he had been seeking for and had found gold,\nand offering to discover the locality for a certain reward;\nand somewhat later Mr. Lancefield forwarded a specimen weigh-
ing 34 ounces, which he had found in the river Turon, near its\njunction with the Macquarie, with a similar proposal.
Bathurst and Wellington, about 180 miles west of Sydney. When the government officer was sent in May to examine the place, he was received with kindness by them. The governor immediately issued a proclamation claiming the gold for the Crown, and forbidding any person to dig for it on his private account. But this it was found at once to be quite impracticable to prevent, and no restrictions were given by the governor to grant licences at the rate of 80s. per month. By May 20th there were 1000 persons employed in digging and washing at Summerhill Creek and its neighbourhood, which took the name of Ophir. In July colonists arrived at three places on the colony's borders and in Victoria; and from that time the discoveries of fresh localities still richer in gold have been made almost without intermission.

On the 3rd of June the governor ordered a reward of 500£. to be paid to Mr. Hargraves, who subsequently received a terminus of the colony as his pennonier; in 1858 a further sum was awarded to him, making his reward in all amount to 5000£.

Policemen were appointed to the various stations, and escorts furnished for bringing the gold from the diggings to the ports of Sydney or Melbourne. An assay-office was subsequently established at Adelaide, and a mint has been established at Sydney. The effect of the gold discovery on the colonists was most extraordinary. In a short time the towns and villages were deserted, all the usual avocations were at an end, and even the ships on Rinn, to which every one capable of labour repaired to the diggings, so that serious apprehensions were entertained that the growing crops would be left ungathered, the wool of the numerous flocks of sheep and cattle would be destroyed, and the principal towns would be deserted. These evils were for the time fortunately averted: the colonists exerted themselves to obtain assistance, and on the news that gold was to be had for gathering being made known in England, an immigration ensued almost without a parallel. It is computed that there were from 90,000 to 100,000 persons left London for Sydney and Melbourne, and it was found difficult to provide ships to convey them. The emigration from England during 1850 was an equally large scale, but has since somewhat diminished. [Note: The population of the colony has increased in the proportions of provisions rose greatly, particularly at the diggings, which are usually in remote districts, to which there are no roads; the sheep instead of, as previously, being shorn and their carcasses boiled down for tallow, were driven to the diggings for food, and the wool and skin thrown away. The effect on the public revenue is shown in a striking manner by a comparison of that of the colony of Victoria in the first three quarters of 1851 and 1852. In the three quarters ending September, 1851, the total revenue was 230,176£., in the three quarters ending September, 1852, it was 979,476£. 3s. 1d., being an increase of 763,304£. 14s. The revenue of Victoria in 1857 was upwards of 3,000,000£. From the first discovery of gold on 4th February, 1851, the amount of gold mined in Victoria has reached a total of 10,000,000£.; of this gold found in the colony of Victoria alone stated by colonial authorities to have amounted to 5,166,234 ounces, of the estimated value of 19,373,577£. The gold exported from Victoria during the year 1857 amounted to 5,652,793 ounces, valued at more than 10,000,000£.

The places where gold has been found are now extend from the Grafton range, New South Wales, in 26° S. lat., 149° E. long., to Ballarat in Victoria, 37° 7' S. lat., 144° 15' E. long.; while two small gold fields have been discovered about 27 miles from Adelaide, South Australia, 33° 3' S. lat., 135° 30' E. long. What may be called the main gold region of New South Wales alone, including no portion of the northern district, where gold has been found in considerable quantities, and where gold-mining has extended the most, is that district of Victoria, where the gold has been officially estimated by the government commissioner, the Rev. W. B. Clarke, after several surveying journeys, to embrace an area of 16,000 square miles; and this he says, in a subsequent report, "is strictly within the limits of truth, and very far from being exceeded." The gold is found generally among the mountains, in creeks and gullies, and the other water-courses, and on the flanks far above the water level, but usually at elevations not exceeding 3000 feet above the level of the sea. It is found in granite, wherever quartziferous schist occurs, throughout the Alpine formations, and largely in bands of argillaceous iron ore.

Copper, as has been mentioned, had been found in large quantities in South Australia some years before gold began to be discovered there. The first of any consequence, was discovered and opened with great profit in 1842. In 1845 the Barra Barra mine, apparently one of the richest in the world, was discovered. The total quantity of copper from this mine up to September, 1851, was 72,795 tons. The mine occurs in the clay-slate formation; the lode runs from east to west. Many other copper and some lead mines have since been opened in the colony, with more or less success. The gold excitement has for a while almost entirely submerged the copper industry, and thecareful examinations which have been made of the gold regions, especially those undertaken by the government geological surveyors, have made known the existence of numerous and widely-spread metalliferous veins, of considerable value. Some of the copper workings have been passed away, lead to most important mining operations. The value of some of these regions may be estimated from the fact of the discovery of a large deposit at a distance of half a mile from the town of Broken Hill, near the junction of the Slaughter-House Creek with the Delegate River, about 37° 3' S. lat., 149° 14' E. long., near the boundary of New South Wales and Victoria. The district is occupied by salt-bush, traversed by quartz and trap, with occasional patches of granite; but, he says, "what renders this locality so interesting and full of promise is the fact, that in addition to the four metals, gold, iron, lead, and copper, existing in so narrow a compass, there is also abundance of excellent limestone to serve as a flux in case of its requirement, and abundance of gypsum, which occurs in large masses along with wood upon the ranges at no considerable distance." The whole basin of the Murrimbidghee, from near Bullanamang to the junction of the Queenbaryan River, is also said by Mr. Clarke to exhibit a well-defined formation of ironstones, nearly水平 occur in conjunction with abundance of limestone; quartz porphyry is here the prevalent rock. And in other districts the metals have been found under equally promising circumstances.

Lead has been found near 31° 36' S. lat., in New South Wales, and worked successfully at Yattagolings mine, where the average yield is said to be 75 per cent. of lead and 18 to 20 oz. of silver to the ton of ore; it is also worked at some other mines. In the great mountain ranges of Victoria and New South Wales there are frequently found, in many places; it has also been found in the Darling Range and near Murchison River in Western Australia.

Iron ore abounds on the eastern coast of New South Wales, where also good coal is found in large quantities; whence we may conclude that at no very distant period the eastern side of Australia may be studded with iron foundries, distributing their products over Southern Asia and among the numerous islands of the Indian and Pacific oceans. It is suggested to the iron-works of the mountain districts beyond the Warrumbungil mountains. Argillaceous iron ore occurs extensively in the regions of the Australian Alps. In South Australia iron-ore is said to abound in the mountains on the south coast near Encounter Bay, and in the ranges from Cape Jervis to Black Rock Hill. No iron works have however, we believe, been yet established.

Native silver has been discovered in the mountains of Tin occurs in several places. Blacklead is said to have been found near Adelaide, at Mount Torrens, and in the Beulah Range, South Australia. Manganese and sulphur are also reported to have been found. Indications of quicksilver have been met with in the vicinity of the Ophir gold-field. In the mountain explorations of the mountain ranges, and consequent investigation from various localities in the same district; to which may be added from other authorities and different parts of the country the hyacinth, amethyst, jasper, carnelian, agate, and opal. Copper appears to exist in Western Australia, South Australia, and Victoria, as well as in New South Wales; but the finest beds yet discovered are those about the Hunter River, in the last-mentioned colony, which are extensively worked, and yield a superior quality.

Salt is found over a large part of the country, and the saltworks are numerous and extensive.
Large tracts of limestone occur on the eastern and south-eastern side of the continent; clays fitted for the economical purposes of life are common in many places; there are numerous sandstones which seem well adapted for ornamental buildings; gypsum is found abundantly in the clay or marl, extending from Bathurst to the Hunter River, and in the vicinity of Swan River; and there is roof-slate both in the eastern and western parts of Australia.

Climate. — The climate of Australia differs considerably from that of other countries. One of the most unfavourable characteristics is the long droughts which occasionally prevail. Captain Sturt says:—"The year 1826 commenced the fearful droughts to which we have reason to believe the climate of New South Wales is particularly subject, the interior quality of the soil, and the severe weather with unabated severity. The surface of the earth became so parched up that the minor vegetation ceased upon it. Culinary herbs were raised with difficulty, and crops failed even in the most favourable situations. Settlers drove their locks and herds to distant tracts for pasture and water. The interior suffered equally with the coast, and men at length began to despond under so alarming a visitation. It almost appeared as if the Australian sky was never again to let down rain in the long season of New South Wales, as it was said to occur every 10 or 12 years. They are succeeded by excessively long rains, but afterwards the rains decrease gradually year after year until they again wholly cease for a time."

Another peculiarity is the quick transition from heat to cold. There are instances of the thermometer having varied 25 degrees in 50 minutes. This is owing to the sudden change of the winds. The north-west winds blowing over the great sandy deserts in the interior attain such a degree of heat that the thermometer ranges from 70° to 100°, and it is not unusual for it to exceed 106°. The thermometer then rises suddenly from 50° to 110° in the shade. On the other hand, the south-eastern winds are often excessively cold. If the weather is calm after the north-west winds have blown, the thermometer falls very suddenly, and the cold is frequently followed by a heavy rain. The thermometer in South Australia often falls 40 degrees in a quarter of an hour.

In spite of these occurrences, which are to be considered as exceptions, the climate over most of the settled part of the country, though somewhat too dry, is commonly delightful, and the evenings and mornings as pleasant as in southern Europe. Even the great heat which occurs does not produce relaxing and enfeebling effects on the constitution. In the towns and cities, many stock-keepers leave the town during the summer (from September to March) between 36° and 106°, and in winter (from March to September) between 57° and 95°, its mean being 66°.

In the north little rains are received during the wet season commonly takes place during the summer; on the coast it commences in the beginning of the winter. Dews are very frequent and heavy, and sometimes they fall like a drizzling rain. Hail-storms are common in December and January.

On the low coasts frost is very little felt, but in the hilly districts it is frequent, and very keen on the high terraces on the western side of the mountains, especially on the plains of Bathurst and the plains contiguous to them; these districts are 2000 feet above the sea. It is likewise observed that in these parts of the country the seasons are nearly a month later than on the low district on the coast. The snow lies on the tops of the mountains and occasionally also in the villages in November and December. The weather is occasionally unknown in the neighbourhood of Sydney and other parts of the coast. In his explorations of Tropical Australia, Major Mitchell experienced much frost, the thermometer being on the 24th of June 17° Fahrenheit, or 15 degrees below freezing point: no discomfort was felt from the cold experienced by any of the party, a circumstance which attributes to the great dryness of the atmosphere.

The climate on the eastern coast is very favourable to health; and excepting the period of the extraordinary drought, there is not seen within the present limits of the country, ophthalmia, which occurs in the month of October and November, and is produced by the winds which prevail at that time. These winds are general in nature; but they are un pleasantly warm, but they resemble in some measure the Eastern and Western winds which blow in any other season. They are accompanied with high pressure, and are generally accompanied by high pressure, and are considered as the cause of the then prevailing ophthalmia. The country north of the Hunter River appears to be much less liable to droughts, and the wet and dry seasons occur with considerable regularity; but the temperature is hotter on the whole, and the climate less healthy than further south.

Soil. Productions.—The soil of so extensive a country and where the geological formations are so varied, differs of course very greatly in different parts, and the productions of the agriculturalist vary in almost an equal measure. For a notice of the usual crops and productions we refer to the alphabetical lists already given; we will only say that almost every variety of grain is raised, and generally of excellent quality. The colonies of New South Wales, Victoria, and South Australia are those which best repay the labours of the agriculturist. The soil of Western Australia is of inferior quality, and the produce of South Australia is very inferior. The cultivation of the soil is very far from being neglected, the breeding of sheep and cattle is the chief occupation. South Australia is especially a grain-growing colony; wheat the finest quality is raised, and the crops are very large. Maize, which succeeds excellently in New South Wales, seldom succeeds well in South Australia. Barley and oats are much grown for grain crops. Rye is not very extensively raised. Tobacco is grown largely in the Hunter River district. Cotton-growing is important in North and South Brisbane. Hops are grown in various places. Nearly all European vegetables are cultivated; potatoes form important crops in cool and moist localities. Although Australia was almost entirely without indigenous edible fruits, at the present time almost all of them are now successfully raised there; and the grape and the olive appear likely to take rank among the most valuable of its productions. The vineyards of New South Wales are already extensive, and wine of excellent quality has been made in some cases. The vegetables of the interior are plentiful, but the climate is too dry for the development of an extensive horticulture. The climate in the interior is too dry for the development of an extensive horticulture.
of 200,000 sheep were in June, 1858, under the sole charge of native shepherds. A training institution for aborigines has been established at Adelaide, chiefly by the exertions of Archdeacon Hale, who resides on the establishment. He says that even his "own sanguine expectations did not lead him to anticipate a success so complete and triumphant as that which has attended our efforts, nor so rapid an increase in the number of our inmates." Besides the school-room, mess-room, &c., there are 20 bêtes occupied by native married couples. There is also a small farm, the work of which, with herding, cattle keeping, &c., is done by the inmates of the institution, who are also taught brick-making, building, and other useful occupations. In New South Wales a "native police corps has been established," which the Governor-General reports to be kept in "continual order among the aborigines. There appears," he adds, "to be no difficulty in recruiting for this force, as the young men of the different tribes are found anxious to enlist." Quarterly reports respecting the condition of the aborigines are made by the district commissioners to the governors of the several colonies, by whom they are regularly transmitted to the Secretary of State for the Colonies.

**Divisions, Government, &c.—**The entire island of Australia is a British possession. It is divided by the British government into the colonies of New South Wales, Victoria, South Australia, Western Australia, and the district of North Australia. New South Wales occupies the south-eastern portion of the island, extending from the shores of the Pacific to 141° E. long., and northward to 26° S. lat. Victoria is separated from the north and north-east from New South Wales by the Murray River, and a line coming from its source on the Australian Alps in a south-eastern direction to Cape Howe. Its southern boundary is the Southern Sea; on the west it is divided from South Australia by the meridian of 141° E. long. South Australia extends from 141° to 133° E. long., and northward to 26° S. lat. Western Australia occupies the entire country west of 133° E. long. North Australia occupies the entire country north of 26° S. lat. and east of 133° E. long. The population is chiefly European, except about the south-eastern coast in the colonies of New South Wales and Victoria; Western Australia is very thinly peopled. North Australia is not colonised, the settlement of Port Essington having been abandoned. On this coast there are consequently no European inhabitants, but a considerable number of Malay fishermen have settled upon it. The total population (exclusive of natives and Malays) in 1850 was 355,107, of whom 266,503 belonged to New South Wales and Victoria, 63,700 to South Australia, and 25,804 to Western Australia. It has since very rapidly increased, owing to the immigration consequent on the gold discoveries.

On August 6th, 1850, an Act of the Imperial Parliament received the royal assent, by which representative constitutions were given, as distinct colonies, to New South Wales, Victoria, South Australia, and Western Australia (as well as to Van Diemen's Land); with power to form other districts if necessary, and also powers of modification. The details of the constitutions will be found under the heads of the several colonies. The governors of Victoria, South Australia,
BAILLIE, in ERROR, in civil causes, is now regulated by the Common Law Procedure. [1822] No practical change has, however, been effected by this statute.

BAILLIE, JOANNA, was born at the manse at Bothwell, near Glasgow, in 1792. She was the sister of Dr. Matthew Baillie. The history of her uneventful life is soon told. The daughter and granddaughter of a minister, and of a mother in whose family superior intelligence seemed a common property, Joanna, while trained in the strict manner usual in a Scottish manse, not only received an excellent education, but from her childhood was brought into contact with tragedy and the world of art. She seems to have retained her own mental gifts. Her career through life was quiet, unobtrusive, domestic; her tastes were all studious; her disposition was gentle, kindly, and benevolent. At an early period she removed to London, where her brother, Dr. Baillie, was settled as a physician. After a time, she, with her sister Agnes, took up her residence at Hampstead, which, while from its proximity to the metropolis it allowed her to enjoy ready intercourse with the many friends her literary fame drew about her, insured her at the same time a certain amount of retirement; and here the rest of her lengthened life was spent. She was known and esteemed by the most eminent of her contemporaries of more than two generations, and for very many years, even from the New World based on atmospheric electricity, came to obtain her acquaintance and to listen to her conversation. Those who visited her out of admiration returned adding to that sentiment of affection and respect. She died at Hampstead on the 23d of February, 1851, in her 86th year, having retained her faculties to the last.

Though Joanna Baillie possessed in a large measure that keen and sensitive interest in all that developed the feelings or touched the destinies of others, and that sensibility and sympathetic imagination, peculiar to the female temperament, yet these sentiments had in her instance more of pensiveness and of speculative nature than of fire, and made her seek and find events in her own thoughts rather than in action and experiment. Adventure may be, and has often been, the school of poetry for men; but a woman, and especially one of Joanna Baillie's feminine and modest disposition, must invoke the muse with a serener and more gentle worship. A close and penetrating observer, and gifted with so common genius, yet not favoured with the heights, nor endowed with the inspiration of 'many-mindedness,' which makes poetry of the first order bear to philosophy the same relation that intuition bears to calculation, Joanna Baillie early in life conceived a literary project based on a principle essentially erroneous, but leading to the production of her greatest works, the celebrated 'Plays on the Passions.' The principle on which all these plays were constructed was to select some one of the more powerful passions that agitate mankind, and to exhibit it in full action, by making the hero of the drama completely subjected to it, and by evolving the prompts to which he is represented as paying undivided and uninterrupted allegiance, every incident and situation. Admitting fully the noble poetry with which these plays are filled, and even the deep interest of many positions and events, it is evident that such characters must have a constrained, morbid, and unreal aspect; since in life, as in the dramatic creations of the highest genius, we constantly see that the dominant passion is turned aside or suspended by, it may be transient, but for the time irresistible, counter-thoughts or the force of circumstances; and this is a main reason why her plays have only achieved a partial and temporary success on the stage. Yet the one master passion is often admirably exhibited—laid bare in its most secret workings—subjected to a keen and searching analysis.

It was in 1798 that Miss Baillie published the first volume of her 'Plays on the Passions,' the daughter of 24 years old. As a basis the production met with great success; and a second edition was called for in a few months. In 1802 she published a second volume. Two years later, appeared her 'Miscellaneous Plays.' Among these was the 'Family Legend,' a tragedy, which she used to term 'her Highland play.' It was acted for the first time at Edin-
but not sudden improvements he gradually increased its circulation, and extended its influence, while his good taste and temper led him to abjure all grossness and bitterness of altercation, so far as his temper and situation of life permitted. The schemes for the amelioration of the position of the poor fellow-townsmen, by advocating the establishment of hospitals, friendly societies (savings-banks had not yet been established), and even the abolition of oaths, the gains of the influence he acquired arose from his being among the first who introduced 'leaders' or original editorial dissertations on political subjects into a provincial paper; these leaders being distinguished by the moderation of their tone, their independent spirit and advocacy of positions he held, the force of their style, and their general good sense. In the severely contested election for Yorkshire in 1807, he took an energetic part in support of Lord Milton in opposition to Mr. Ladbrooke, although he differed in opinion from Lord Milton respecting the danger of the Reform Bill on terms, and a reform in parliament, both of which he advocated, while there were few more earnest in supporting the dignity of England when threatened by France, and his appeals to the inhabitants of Leeds to join the volunteers when an invasion was feared, had a most remarkable effect. But we are not about to narrate all the incidents connected with Mr. Baines's conduct of his paper, which was carried on with a strict adherence to the same principles until the close of the Napoleonic wars. He held the principal means, in his paper, of developing, in 1817, the conspiracy of Oliver and Castles, the paid emissaries of the government to foment insurrections in the northern counties, and that after his return to Leeds he made his first prominent appearance as a public speaker at a meeting at Leeds to oppose the enactment of the Corn Laws, and in 1817, at another in favour of parliamentary reform. In 1814 he commenced the publication of 'The History of the Wars of the French Revolution,' which met with such success that he continued it under the title of 'History of the Reign of George III.,' the whole being a compilation of considerable impartiality and talent. In 1822 and 1823 he wrote and published 'The Directory of the County of York,' in two thick volumes; and in 1824-5 a similar work for the county of Lancaster, subsequently expanded into 'A History of the County Palatine and Duchy of Lancaster,' which was not completed till 1856. In 1834, on a vacancy being made in the representation of Leeds by the appointment of Mr. T. B. Macanlay (now Lord Macanlay) to be one of the commissioners in India, Mr. Baines was chosen member in opposition to Sir John Beckett, after a severe contest. In the House of Commons he maintained the character he had acquired in the press, and though not a brilliant speaker, his integrity, independence, industry, and conciliatory manners, with his close connection with the dissenting interest, made him an influential member. In January, 1837, he collected, and generally supporting the Whig party, he was opposed to them in their schemes for public education, which he always contended would be best effected by voluntary subscriptions, and he deprecated the assistance of the State as tending to give a undue domination to the Established Church. In 1841, his health having suffered from the sedulous performance of his parliamentary duties, he retired from the representation, and proposed Mr. Hume as his successor, who however was defeated. In September of that year his former constituent presented him with an elegant silver service as a testimony of their recognition of his services. From that time he retired to some extent from public life, but continued to take an active part in local affairs, both as a magistrate and a poor-law guardian, in both capacities promoting social improvements as far as lay in his power; and he was always ready to interpose as mediator between the men and their employers in the many strikes that took place in the north, representing to the men the folly of their having recourse to violence in endeavouring to effect their object, and who recommended the desirability of placing the men in as comfortable a position as the circumstances would allow. In 1845 the Leeds Mercury warned the speculators of the danger attending the railway schemes then proposed; he seized the advantage of the railway system. He saw that though the facility of communication was a great good, yet that if it became a mere traffic for premiums, it was likely to produce much disorder. In 1846 he had declined to accept the office of postmaster-general, his fellow-townsmen chose him for alderman as a mark of their respect, but he immediately resigned the office. In 1847 he again opposed Lord John Russell's scheme for state education of the poor, and the opposition of the dissenters was so strong that the plan was abandoned. On August 3, 1848, at a short notice, he died, and was honoured by a public funeral.

Balbi, Adrien, was born at Venice, April 22, 1783. At an early period of his life he was appointed professor of geography at the University of Padua. He published in 1826, with the assistance of Dr. A. F. von Humboldt, a work entitled 'Essai Statistique sur le Royaume de Portugal et Algavre, compare aux autres Etats de l'Europe,' published in Paris in 1831. He was one of the first to collect and publish charts of the European seas. He published in 1828 the first volume of his 'Atlas Ethnographique du Globe; ou, Classification des Peuples anciens et modernes d'apres le Langage des peuples qui les avaient precedes.' He was acquainted with the researches of Adelung and other German philologists. Balbi however improved their arrangement, and added much information gathered from the accounts of such travellers as A. von Humboldt, Freycinet, and others, as well as from linguists such as W. von Humboldt, Remusat, Champollion, Klaproth, &c. This work attained a deservedly high reputation. Under the administration of Martignac, Balbi received from the government such pecuniary assistance as rendered his circumstances comfortable. He resided for some time at Turin, and afterwards at Florence, where others whose help he has scrupulously acknowledged, statistical tables of the kingdoms of France, Russia, and the Netherlands. After finishing his 'Abrege de Geographie,' he was appointed professor of geography at the University of Padua, where he made himself into one of the principal languages of Europe, he quitted Paris in 1833, and settled at Padua, where he died March 14, 1848.

We have mentioned the works on which Balbi's reputation rests, but he produced several others, among them are:

- 'La Monarchie Francaise compare aux principaux Etats de l'Europe,' 1828;
- 'L'Empire Russe compare aux principaux Etats du Monde,' 1829;
- 'The World compared with the Traders of the Great States.'

Balbriggan, county of Dublin, Ireland, a seaport and post-town in the parish of Balrothery, and barony of East Balrothery, is situated in 53° 46' N. lat., 6° 10' W. long.; and distant by the Dublin and Drogheda railway, which has a station here, 91 miles N. from Dublin, and 104 miles S. from Drogheda. The population in 1841 was 2922, in 1851 it was 2310. The harbour is formed by a pier of 200 yards in length, at the extremity of which is a lighthouse. Although dry at low water, the harbour has been found very useful as a port of refuge. The land of the district is very much the same, with the exception of some few large fields, which are most highly esteemed for the manufacture of distilleries and a brisk trade in the manufacture of cotton, and of a very fine description of hosiery. Many of the females are employed at the distilleries, and in the manufacture of the fishery, for which Dublin is the market.

The constabulary and the coast-guards have each a station here. Quarter and petty sessions are held, and there is a savings bank. Fairs are held on April 29th and September 29th.

Baldock. [Hawkinsianus.]

Ballina, county of Mayo, Ireland, a seaport and post-town, and the seat of a Poor-Law Union, in the parish of Kilimorey and barony of Tirywall (with the parish of Ardmore, in the parish of Kilimorey, barony of Tirywall, and county of Sligo, is situated on the Moy river, 7 miles above its embouchure in Killala Bay, in 54° 7' N. lat., 9° 10' W. long.; 159 miles N.W. by W. from Dublin. The population in 1841 was 7012; in 1861 the population was 8639 (being 4647 in Mayo, and 4005 in Sligo county); besides 1336 inmates of the Union workhouse. Ballina Poor-Law Union comprises 90 electoral divisions, with an area of 105,414 acres, and a population in 1841 of 127,354, in 1851 of 53,611.

The two bridges which cross the Moy at Ballina are in the county of Sligo and the northern baronies of Mayo. The situation is also favourable for the export of agricultural produce. The town is modern, well built, and clean. On the Mayo side are the principal church and a spacious Gothic Roman Catholic church, which serves as a cathedral to the Roman Catholic diocese of Killala. There are here a court-house, and chapels for Baptist and Wesleyan Methodists. On the Sligo side are the parish church and a spacious Gothic Roman Catholic church, which serves as a cathedral to the Roman Catholic diocese of Killala. A brisk trade is carried on in the export of agricul-
tural produce. There is a very productive salmon fishery. A few hospital and a dispensary are in the town. Ballylinne has a station of the constabulary force. Quarter and petty sessions are held; there are fairs on May 13th and August 18th.

The surrounding scenery is remarkably fine, having a fertile and very extensive plain towards the sea, bounded on the south and east by the range of the Oran Mountains in Sligo, and on the west by Nephin Mountain (3,646 feet), and the highlands of Erris. Ten miles north-east of Ballylinne, near the shore of Killala Bay, is the ruined castle of Lesaan, now called Castle Durbos, remarkable as having been the patriarchy of the ancient church of Ireland. It was once a residence of hereditary scribes and historians of the ancient Irish territory of Hy-Fiachra.

(Trives and Customs of Hy-Fiachra, Published by the Irish Archaeological Society, Dublin, 1844; Thom's Irish Almanac)

BALLYRIN, county of Mayo, Ireland, a market and post-town, and the seat of a Poor-Law Union, in the parish of Barrineau, and barony of Kilmain, is situated on the Rube River, 3 miles from its embouchure in Lough Mask, in 53° 27’ N. lat., 5° 22’ W. long; distant 141 miles N.W. by W. from Dublin, and 4 miles S.W. from Holywood on the leading road from Tuam to Castlebar. The population in 1841 was 2673, in 1851 it was 1012, exclusive of 2650 inhabitants of the Union. Ballyrinne Poor-Law Union comprises 18 electoral divisions, with an area of 144,888 acres, and a population in 1841 of 58,113, in 1851 of 37,255.

Ballyrinne is picturesque situated chiefly on the left bank of the Rube River, and in the union and townlands of Ballyrinne, Quinrhin, and in the town is a barracks station and a station of the county constabulary force. A market for agricultural produce is held weekly, and fairs on Whit-Monday and December 6th. BALLYOTA, a genus of plants belonging to the native order of Liliaceae, the most remarkable species of which is B. tecta and B. tectorum. B. tecta is the most common plant, and goes by the name of Horehound. The White Horehound is the Marrubium vulgare.

(Maxwell's Irish Flora)

BALLYMENA, county of Antrim, Ireland, a market and post-town, and the seat of a Poor-Law Union, in the parish of Kirkinstol and barony of Lower Toome (with the suburb of Harreville in the parish of Ballyclug and barony of Lower Antrim), is situated on the right bank of the river Bann, 3 miles from its mouth in 54° 50’ N. lat., 6° 15’ W. long, 33 miles N.W. from Belfast by the Belfast and Ballymena railway, and 118 miles N. from Dublin. The population in 1841 was 5669; in 1851 it was 6136, besides 337 in the Union workhouse. Ballymena Poor-Law Union comprises 23 electoral divisions, with an area of 100,853 acres, and a population in 1841 of 74,130, in 1851 of 71,133.

Ballymena stands in the midst of a very densely-populated district, extending from the neighbouring town of Broughshane on the river Bann on the west. The population here unite the manufacture of linen with the pursuits of agriculture, and Ballymena is their chief market possessing a very considerable and flourishing trade both in linen and agricultural produce. There are two large markets a week, and a considerable appearance. There are an Episcopal, a Roman Catholic, a Wesleyan Methodist, and three Presbyterian places of worship; a market-house with a spire, the Union workhouse, a dispensary, and a bridewell. Quarter and petty sessions are held at the river Bann on the west. The population of the county constabulary, Saturday is the market day. Fairs are held on July 28th and October 21st. In the vicinity are extensive bleach-grounds. The surrounding district, although divided into very small holdings, is cultivated to a high degree, and presents a rich and pleasing landscape.

BALLYMONEY, county of Antrim, Ireland, a market and post-town, and the seat of a Poor-Law Union, in the parish of Ballymoneey and barony of Upper Daniele, is situated on the left bank of the river Bann, in 53° 4’ N. lat., 6° 31’ W. long, 18 miles N.W. by N. from Ballymena, 54 miles S.E. from Coleraine, and 140 miles N.N.W. from Dublin. The population in 1841 was 4640; in 1851 it was 6656, exclusive of 373 in the Union workhouse. Ballymoneey Poor-Law Union comprises 33 electoral divisions, with an area of 137,115 acres, and a population in 1841 of 50,710, in 1851 of 42,418. The town is irregularly built on a small stream which runs into the river Bann. There is a Roman Catholic church, and the houses are mostly built of stone. It is a chapel for Roman Catholics, several chapels for Presbyterians, a town-hall, a dispensary, the Union workhouse, and a bridewell. Quarter and petty sessions are held, and there are here stations of the constabulary and the revenue police. Ballymoneey has a small trade in linens. A market for linens and dairy produce is held monthly, and fairs are held on May 6th, July 10th and October 10th.

(BALM. [CALLAMINTA, S. 1; MELMIRA, S. 1])

BALM, A. I. B.

BALZAC, HONORE DE, a French novelist, was born at Tours, May 20, 1799. He was the son of a clerk under the government of Louis XV. At the college of Vendome, where young Balzac was sent early, he gained the character of an idle and disobedient student, and was removed to a private academy. On leaving school he was placed with a notary in Paris, but he almost immediately commenced writing articles for the journals. These are said to be rather testimonies of his perseverance than monuments of his genius. Between 1821 and 1827 he had published some of these, none of them exciting or deserving much attention, under the assumed name of Horace de St-Aubin. In 1826, in connection with one Barbier, he commenced business as a bookseller and editor. Among other things he published an edition of Fontaine's works, with which he had written himself, and commenced the 'Annales Romantiques.' His speculation was altogether unsuccessful. In 1829 he appeared before the public for the first time, under the name of 'The Last Chauve,' and the scene of which was laid in Le Vende, which district he had visited.

It was not however till the publication of his 'Peau de Chagrin,' in 1838, also under his own name, that the Parisians became acquainted with the talent which had distinguished his works. From that period he was a general favourite in France, and many of his productions have been translated into most of the languages of Europe. He was indefatigable in supplying the public with new stories under the title of 'Comédie Humaine.' He planned a series of productions that was to embrace every phase of human society; and at this he worked for twenty years. Among the most popular were 'La Femme de Trente Ans,' and 'Le Père Goriot.'

On the publication of the 'Médécin de Campagne,' in 1835, Balzac received a complimentary letter from the Countess Eveine de Hanska, the wife of a Polish nobleman, possessing large estates in Russian Poland. Balzac replied, and an intimate correspondence between the two followed which his novel of 'Séraphita' was dedicated. The countess became a widow, and a few months after the revolution of February 1848 Balzac quitted Paris to bring her back as his wife. He inhabited a large house near the Champs-Elysées, which he adorning with a multitude of chefs-d'oeuvres of art, and in which he hoped to find happiness and peace. But even before his journey he had been attacked by a disorder which it was found impossible to cure or to postpone—of which he died August 20, 1850. He was buried in the cemetery of Père-la-Chaise, an immense crowd attending the funeral; and Victor Hugo pronounced a critical eulogium over his grave. In that eulogy, he says, 'Balzac is a dead genius; he is no more; but his influence is felt. He is a voice in the heart of all men; a man of conscience, a man of feeling, a man of imagination, a man of truth, a man of kindness, a man of modesty, a man of humanity.'

(Nouvelle Biographie Générale)

BANAGH, county of Down, Ireland, a post-town in the parish of Reynagh and barony of Garrycastle, is situated in 53° 12' N. lat., 6° 54' W. long., on the left bank of the river
Shannon, which is here crossed by a bridge leading to Galway by way of Eyrecourt; distant 24 miles S.S.W. from Shannon harbour, where the river is connected by the Grand Canal with Ballinasloe on the west, and Dublin on the east, and 58 miles W.S.W. from Dublin by the high road. The population in 1841 was 5,292; in 1851 it was 5,864. The town is built on the intersection of the Brr and Eyrecourt road with that leading from Shannon harbour to Limerick. The old bridge of 18 arches was removed in 1843, and a new bridge of 6 arches of 60 feet span each, with a skewed arch of 45 feet span for the passage of vessels, was erected in its stead by the Irish Board of Works. At the eastern end of the bridge is a barracks and a magazine, and there are batteries which command the bridge and its approaches on both sides of the river by Blarney, chiefly in the direction of Killarney and distillation. 

Prior to the Union, Banagher was a corporate town, and returned two members to the Irish Parliament. Petty sessions are held here. Fairs are held on May 1st, September 15th, October 28th, and November 8th. The adjoining district is flat, and in the immediate vicinity of great tracts of bog, but it is well cultivated.

BANBROOK, county of Down, Ireland, a post-town and the seat of a Poor-Law Union, in the parish of Seapatrick and barony of Upper Iveagh, is situated on the south bank of the river Bann, on the leading road from Newry to Belfast, in 54° 20' N. lat., 6° 16' W. long., 13 miles N. by E. from Newry, and 76 miles N. from Dublin. The population in 1841 was 2852; in 1851 it was 3201, exclusive of 478 inmates of the Lunatic Asylum. The Bann Bridge Union consisted of 23 electoral divisions, with an area of 194,929 acres, and a population in 1841 of 87,100, in 1851 of 74,644.

The principal part of the town is built upon an eminence, having no streets leading towards the coast; and owing to this inconvenience, the centre of the main street, which was of width sufficient to admit of the alteration, was lowered to a depth of fifteen feet, leaving elevated causeways on each side. In carrying this arrangement into effect, it was necessary to remove the old market-house with its gardens in the middle of the street on the summit of the hill: a viaduct connecting the opposite terraces now occupies the site. The town consists chiefly of this main street, and is substantially an open space with no built-up area, and is consequently the new market-house and church. The church is pleasingly situated on a level green adjoining the bridge, on the right bank of the river. The Wesleyan Methodists have one chapel, and the Presbyterians have three chapels. Petty sessions are held here, and there is a station on the constabulary line.

Twelve fairs are held in the course of the year. The linen trade in all its branches is carried on with great activity in the immediate neighbourhood. The line of the Bann, traversing the county, distant 6 miles above the town to the border of Armagh, forms an admirable level for the cultivation of bleach-greens. At Huntley Glen, a little below the town, is a large thread-spinning factory; and at Seapatrick an extensive establishment for weaving union cloth by machinery. Seapatrick also has a paper mill, which is about this a very early period. In the itinerary of King John, a.d. 1210, the place is mentioned under its present name.

FRAZER, "Handbook for Ireland; Original Communicating.

BAND-FISH. [Cephal.] BANFF.

BANKRUPTCY. The numerous statutes relating to bankruptcy have been consolidated by the Bankruptcy Act passed in 1847; and which has been amended in one or two omission, is c. 17, sect. 17. A class subject to these laws, traders, has been further defined and extended, and the proceedings in court simplified. They are commenced by a petition either by the trader himself, or by a creditor or creditors; upon which an adjudication is made, and after notice, gazetted; there being an appeal to the Lords Justices of the Court of Appeal in Chancery, as coming in place of the Court of Review, and from them to the House of Lords. Meetings for the examination of the bankrupt, and for the debts and dividends. [Bankrupt, s. 1, p. 171], the property of the bankrupt is estimated in the mean time vested by the adjudication in an official assignee, and on a choice being made by the creditors, in him and his assignees jointly, the control of the Court being vested in such assignees for the collection or application of their estate. Companies incorporated by Charter or Act of Parliament (7 & 8 Vict. c. 111), insurance companies, and banking companies of more than seven partners (7 & 8 Vict. c. 112), may be made bankrupt. Joint Stock Companies, with limited liability, are wound up, when necessary, in the Courts of Bankruptcy; and the Court of Chancery may send the winding-up of companies, whose liability is unlimited, to this tribunal (19 & 20 Vict. c. 47; 20 & 21 Vict. c. 14; Blackst. Comm., Mr. Kerr's ed., vii. ii p. 494. See also insolvency.

The bankrupt laws of Scotland have been consolidated to some extent, and the procedure in a sequestration simplified and cheesepased by the statute 19 & 20 Vict. c. 79.

A similar observation on the subject of bankruptcy in Ireland. The laws relating to bankrupts and insolvents in that part of the kingdom have been consolidated, and the administration thereof committed to a new court called 'The Court of Bankruptcy and Insolvency' (20 & 21 Vict. c. 60).
George Stannum, to whose son he had given lessons in mathe-

matics, the appointment nominally of comptroller of the

household to Lord Macartney in 1797 to go to China; but rea-

ly to take charge of the various philosophical

instruments carried out as presents to the emperor of China.

By this means Mr. Barrow secured so far the good-will

of Lord Macartney, that his lordship made him his private

secretary on being appointed Governor of the Cape of

Good Hope in 1799; and when Lord Macartney quitted the

Cape in 1798 he left Mr. Barrow in the post of ad interim-

public accounts. During his stay at the Cape Mr. Barrow

devoted his leisure hours to the study of the geography and

natural history of South Africa, and made several journeys

into the interior. At the time of his return to England he published

the results of his investigations in a short volume entitled

'Travels in Southern Africa.' In 1804 Mr. Barrow was

appointed by Lord Melville to the responsible post of second

Secretary to the Admiralty, the duties of which he continued

to discharge for a period of forty years under thirteen

administrations.

In this office Mr. Barrow was earnest and

indefatigable in the promotion of every project which com-

mended itself to his judgment as calculated to advance the

progress of geographical or scientific knowledge. Especially

indebted is he to the support of the scientific policy of the

various governments under which he served, and to the

country, the prosecution of the various voyages to the Arctic

Regions which have so characterised the naval history of

England during the last sixty years of its reign over the

Admiralty; and though his services had been fully com-

memorated by associating his name with the point of land, Cape

Barrow, yet such was the sense entertained of them by those

officers who had been engaged in those voyages, that, on

his retirement from the office in 1844 he was presented

with a costly candelabrum, bearing a suitable inscription on

the pedestal.

Mr. Barrow was a man of uniting industry. The leisure

hours afforded by his official employment were devoted to

literary and scientific pursuits; and which literary labours in

what extent have seemed unworthy of one whose whole

time was given to literature. Neither in literature nor

science would he be regarded as having attained a high place,

but for many years he held a distinguished position in the

literary and scientific circles of the metropolis.

He was for a long period a member of most of the leading learned

societies of London. In 1805 he was elected a Fellow of the

Royal Society; in 1830 he took a leading part in the founda-

tion of the Geological Society; and in 1840 he was

chosen president. In 1835 he was created a baronet.

In the beginning of 1846 Sir John Barrow, then in his

eighty-first year, resigned his office at the Admiralty, and

retired to Bath, where he lived in the same mansion at Stew Hill, Bath, filling in

his apartments with a choice collection of scientific and

literary books, engravings, and other productions of taste and elegance. But

the decoration which he specially prized was a large fresco,

30 feet long by 12 feet high, which he painted upon the wall of one of the rooms: it represents the Inroads of the

Turks upon Scio, in April 1822, and is a most elaborate

composition. His friends and admirers describe it as the noblest

of his productions; but neither the character of his mind

nor his training as an artist qualified him for a painter of history. He died December 11, 1847, in the 79th year of his age.

BARRHEAD, Renfrewshire, Scotland, a small manufac-
turing town of recent growth, in the parish of Neilston, 3

miles NE. of Neilston, 10 miles NW. of Glasgow, and 3

miles E. of the Ayr Railway. It is connected with Glasgow and Ayrshire by the

Glasgow, Barrhead, and Neilston Railway. Spinning, weaving, and bleaching works are carried on here. The town, in addition to its neat railway station, possesses a chapel of ease and two meeting-houses, one for a congregation of the Free Church, and the other for United Presbyterians: the population of Barrhead in 1861 was 6000.

BARRISTER. [Barrister.] In order to be called to the

Bar of England it is necessary to pass an examination in the Acts of Parliament in

the Halls of the Inns of Court, which are delivered by Readers or Lecturers appointed by the Benchers for that purpose, or to pass an examination conducted by

Readers, who are paid partly by the Inns of Court and partly by the subscribers to the 'Biographical Memoirs of the University of Oxford.'

To encourage students to submit to examination,

three studentships or bursaries of fifty guineas are given

away annually to the student who has best answered the

questions of the examination.

In England, in preliminary education, the shape of

an examination in classics and arts, has been imposed on

persons applying for admission to the Faculty of Advocates.

BARR, SIR JOHN, was born at Drayage Back, near

Dover, Kent, February 11, 1805, and was educated at the Town Bank Grammar School, young Barrow was placed when about fourteen years old as clerk and overlooker in an iron-foundry at Liverpool, but quitted this situation two years afterwards to make a voyage in a whaler to Greenland, where he saw the sea-

way, and served as mathematical teacher in a school at Greenwich, when he obtained in 1792, through the influence of Sir

J. B. (John Barrow, son of the subject of the above article) and the Rev. W. B. BARR, M.A., D.L., among others, was born at Pembridge, Herefordshire, on March 16, 1802. The strong bent which he early manifested for scientific pursuits, led his parents to give him a mercantile life for their son, and he studied in the universities of Edinburgh, Paris, Berlin, and other places for three years, but returned to London. He entered warmly into the proceedings of the societies of the Scottish metropolis, and spent most of his
holidays in geological and botanical excursions on foot among the lakes and mountains. He took his degree of M.D. at Edinburgh in 1833, and in the following year, after a term of study at Heidelberg, he rambled through Switzerland to Chamouni, where, though past the middle of September, too late in the month, as he thought, for snow to have fallen on the summit of Mont Blanc. This was the sixteenth ascent, and Humboldt was so pleased with the narrative of the adventure published by Barry in 1836, that he personally requested him to translate his "Two Attempts to ascend Chamonix and the German Alps" into English.

Martin Barry has the merit of being one of the few physiologists who devoted their attention to the difficult question of animal development and embryology. He began by making himself well acquainted with the literature of the subject, and in 1835 he published an "Account of the Development of the Viscera of a Frog," and in 1836 an "Account of the Development of the Ears of a Frog," which attracted much attention. He then, in 1837, published "On the Development of the Heart of Man," and in 1838 a "History of the Development of the Heart," which was received with great interest.

Having published in the "Edinburgh Medical and Surgical Journal" for 1836, a translation of the first part of Valentin's "Manual of the History of Development," he commenced his investigations into the development of the mammalian ovum and its parts. The results are, as is well known, "the most important part of embryological science." The results, communicated to the Royal Society of London, were printed in the "Philosophical Transactions," and in 1838 he published "The Development of the Ovum," which was received with great interest.

The Royal Society recognised the value of Barry's researches by awarding him his royal medal in 1836, and electing him a Fellow in the following year.

The "Researches in Embryology" exhibit proofs of the author's sagacity and selection of his facts, and of the perseverance by which they were demonstrated. He explains the formation of the ovum in the rabbit and dog, and in some of the oviparous vertebrate classes from the bird to the bat. He describes the order of formation of different parts of the ovum, and the nature and mode of its growth from the ovum; and showed that the so-called "disc of Von Baer" contained a retinaculum, or peculiar species of mechanism, by which, as he supposed, the passage of the ovum into the fallopian tube was regulated. He described the changes that take place in the ovum while on its passage—changes before unknown—and Barry was the first to throw light on this interesting process of animal development. Not until his paper appeared in 1836, was it known that the segmentation of the egg while the ovum was being observed in Batracian reptiles, was also true of mammals. It was an important discovery; and not less so that published in 1840—the penetration of the ovum by the rabbit, by spermatic or seminal fluid in the human being. When he first was doubted; but he confirmed it by further observation in 1843; and it was eventually corroborated by the observations of Nelson and Newport, accounts of which are also published in the "Philosophical Transactions," and Professor Bischoff, who had depicted the truth of Barry's conclusions, at last satisfied himself of their accuracy, and accepted them in full.

The views expressed by Barry in his paper "On Fibre," are opposed by physiologists. He attributes the power of muscular fibre and other organic tissues, and brought speculative arguments to bear in favour of his opinions; but other investigations show one and the other to be fallacious. His speculations have however tended to stimulate physiological research. What he may have been Barry's feeling, for his own favourite ideas, his character as an amiable and benevolent man is beyond question. Ample private circumstances placed him above the need of practising his profession; but he sought for his poor, chiefly as house-surgeon to the Royal Maternity Hospital at Edinburgh. From 1840 to 1853 he lived on the Continent to recruit his health and eyesight, both having suffered from long and severe study. At Prague he renewed his examination of muscles, especially with results which may be seen in Müller's "Archiv." for 1850. In 1859 he returned to Scotland, suffering much from neuralgia; and having gone to reside at Bexley, in Suffolk, he died there on the 27th of April, 1855. He was a member of the Society of Friends.

Barry was a member of the Royal Society of Edinburgh, of the Wernian and other societies, and the College of Surgeons in that city. Some of his papers and translations appeared in the "Edinburgh New Philosophical Journal," and others in the works and periodicals already mentioned.

BARTON, BERNARD, was born in London in 1784. His parents were members of the Society of Friends, and to the tenets of that sect Bernard Barton always adhered. In 1800 he entered Pembroke College, Cambridge, where he entered as a clerk the banking-house of Messrs. Alexander, in whose employment he continued almost to his death. Bernard Barton first claimed public attention as a poet in 1812, by the publication of a volume of "Metrical Effusions." His 'Muse and the Muse,' his 'The Captives of Weymouth,' and his 'Ode to the Muse,' were published successively. Thenceforward as long as he lived he continued to issue at intervals either brief occasional pieces, or, though much more rarely, a poem of greater length and loftier pretensions.

Bernard Barton attracted an amount of attention and popularity far beyond that to which his poetic merits would seem to have entitled him. This was perhaps mainly owing to his presenting the then unusual phenomena of a Quaker poet—the title indeed by which he came to be commonly known—more extensively than it had hitherto been. The evidently unaffected tones of simple religious earnestness which pervades all his writings. He wrote with ease; and like most easily written poetry, his verses are more characterized by fluency than power. But though often without philosophical, moral, or polished effect, they contain much of vividness and quiet unobtrusive benevolence running through his verses, which render them pleasing to all but the more critical class of readers. Barton was a man of refined habits; a lover of natural scenery, and a good talker, if his conversation was in no degree too much used beyond the common among members of his sect. His moral character was blameless, and few men in his position of life won so wide and general a share of esteem as did Bernard Barton. Some years before his death he received a valuable instrumentality for his son due to the grant of a pension of 100l. per annum. He died suddenly of apoplexy, February 19, 1849. Besides the works noticed above, Barton published "Napoleon and other Poems," "New Year's Eve," and "Household Verses," "New Year's Eve," and numerous occasional verses and poems published separately, and in magazines, annuals, &c.

BASEVI, GEORGE, an eminent architect, was born at Brighton, in 1794. He was placed as a pupil with Sir John Soane, R.A., in whose office he remained for six years. He then made a professional tour through Italy and Greece for three years. During his tour, and during his residence in Athens, he made many drawings. While furnishing drawings for a castellated tower for Lord Elgin, he was employed in the construction of various descriptions of buildings, scarcely any one of which is without manifest evidence of care and attention. From 1816 to 1829 he resided at the close of his extensive work was broken up by the death of his wife, and the sale of his house. His last work was a town house, the sale of which was prevented by the death of the owner. He died, July 4, 1841. His work was the Fitzwilliam Museum at Cambridge, one of the most ornate yet chaste and effective classical edifices erected in England. Its external stonework is of unbroken beauty, and its internal arrangement of great skill. His death, and, like the Conservative Club-House, St. James's street, another of his latest works, executed by him in conjunction with Mr. Sidney Smirke, it shows that he was rapidlythrowingoffthetronnalsofprecedent, andgivinghis fine taste and attainments full scope. His reputation rests on the virtuosity of his own works, not on the vagaries of his predecessors. His career was suddenly cut short by a lamentable accident. While examining, in company with the Dean of Ely, the works in the Bell Tower of Ely Cathedral, the restoration of which was being conducted under his direction, his foot slipped on a step, and he fellfrom the top of the tower. He was immediately notified, and sent in an ambulance to the hospital. He died almost instantly, October 16, 1845, aged 61. The Fitzwilliam Museum is now completed and opened under the direction of Mr. Cockerell.

BASSE. [Lanx.]

BASTIAT, FREDERIC, was born at Bayonne, June 29, 1801. He was the son of a merchant, by whom he was
ulty destined to a commercial career. After receiving a
good education at the College of St. Sever, he was placed in
his youth, entered into the mercantile world, and devoted
himself studiously to the study of the principles of trade; and,
having to visit Spain and Portugal on business in 1840,
he submitted himself voluntarily to the study of the com-
mercial regulations of those two countries, lodging behind
every town on the road, and the poor in outposts, but was
at length communicated to the public by M. Bastiat, in
1844. It appeared in the 'Journal des Économistes,' under
the title 'L'Influence des Tarifs Français et Anglais sur l'Es-
cyan des deux Peuples.' In this the author avowed himself
a protectionist. He called to mind the famous dictum of
Adam Smith—a principle at that time universally acted upon
in France, and almost as universally recognized as just and
credible. Bastiat, however, gained adherents, and time
and success resolved the principle into practice, for ex-
ample, of England, and France. (The Frenchmen in Eng-
land forward till they see something overtaken by the Frenchmen, and appear likely to be
extended still further. In 1846, after a visit to England,
where he had made the acquaintance of Mr. Cobden, he
unloaded, under the following title, many of the addres-
ses of the Free-Traders, preceding them by an introduction:—
Cobden and the League; or the English Agitation for the
Freedom of Exchange.' In this he adduced all the incon-
veniences of a prohibitory system. He became secretary in
Paris to the Free-Trade Union, member of the Committee of
Trade, and editor of a journal devoted to the same cause. While this
advocating sound commercial principles, he was opposed to the
principles of Socialism, and the pretended right of every one
to live at the expense of his neighbour. He was not set for some time in the Legislative Assembly, but his
health failing, he proceeded to Italy in hopes of improving it,
and died, at Rome, December 24, 1849.

M. Bastiat wrote many works besides those mentioned,
not all on the same leading subject. Though valuable and
worthwhile, it is not necessary to mention the names of the
works at the time of their appearance, they con-
tinue little that had not been before enunciated in England;
but the views, although not original, are placed effectively
before the reader."

(Notes paragaphiques Générales.)

BATHS AND WASHHOUSES, PUBLIC. In the
article Baru ['P. Cyp.; vol. iv. p. 31] it was said "There
are but few baths in London, and those established there
would not suffice for a small fraction of the population, if
bathing was a common practice. Still of late years baths
have increased both in London and England generally.

The baths here spoken of were private ones of a compara-
tively expensive character. There were indeed a few public
baths; but the poorer sort were not what they should be. The
houses of the laundress carried the linen down to the nearest
convenient spot by the side of a stream, where 'the shore
was shelvy and shallow,' like that which the whistlers (washers)
of Windsor resorted to, by Datchel Mead, where
Fawley was so unceremoniously snatched from the back-
to-bucket. It is on record that the Corporation of Reading,
upon the suppression of monasteries, petitioned for the
grant of the Frary in that town, for a town-hall, because
their old hall stood by the river Kennet, near the spot which
was used by the townswomen for washing clothes; and the
petitioners say in their petition that the noise of the
women's clappers caused great irritation to the transaction
of public business. The petty clappers were, in those populous
cities, washing in cold water, yet they used wooden bulldozers
to beat their clothes, just as the Blanchisseuses of the Seine
do still. In the present day, washing by the river-side is,
we believe, nowhere to be seen in England, but it is common
in many Continental towns. A few years ago it was well
known, that the Parisian laundresses pretty generally resort to washing
beats on the Seine. In Pepys's day, London families would
have to send their linen to be washed by their servants at
a washing establishment; for that most valuable of diaries
tags particularly well acquainted, they, the housewives
alone, "my wife and maids being over the water to the
whister's with their clothes, this being the first time of her
crying this way of washing her linen." Again he notes
(August 19th, 1668), 'This week my people wash over the
water, and so little company at home'; by which we may
suppose that Mrs. Pepys was satisfied with her trial of 'this
way of washing her linen,' as she continued to practise it
for above a year.

It was reserved for our own day to establish public baths and
laundries for the community generally, and for the poorer
portion of it in particular. The practical philanthropist
clearly saw that the sanitary improvement of the condition of
the poor was an important object of national policy, as a
degree of dirt and squarol with which health and morality
were alike incompatible. Many remedies for the evil were
suggested, and several carried into execution. One little
and far-tried mode of procedure would perhaps deserve
special attention to the matter of personal cleanliness.
It had been allowed by all who were really acquainted with
the houses of the very poor, that in their crowded and
wretched dwellings cleanliness was impossible. In such
places not only were there small means for personal
cleanliness, but to wash and dry clothes properly was quite
impracticable. It was proposed, therefore, to see whether
the establishment of places where, for a small charge, a warm
bath could at any time be had, and where all the conveniences
for washing and drying clothing could be obtained. A small
charge of one farthing per hour, or a trifling cost per hour, would be gladly
accepted by the classes most requiring such conveniences.

The movement was practically initiated by the building of a
lavatory in the Market House at Epsom, during the
presidency of the Lord Mayor, in September 1844; when
resolutions were passed for the formation of an 'Association for Promoting
Cleanliness amongst the Poor,' and an active
subscription was commenced. The first experiment was
made in a wretched locality near the London Docks, where
in an open court, called Glasshouse Yard, Rosemary Lane,
old but spacious building, which had for some time been
completed by 'sleeping-baths for the houseless poor,' was rented
and converted into the first Free Baths and Wash-houses,
and opened in August 1846. A portion of the building was adapted,
as well as it could be at a small expense, to the
purpose, and furnished with a due supply of tubs and boilers
and with a few baths in various out-of-the-way recesses;
and soap and soda, as well as hot and cold water, were provided
gratuitously. The number of persons who availed themselves
of the establishment was, in the first year, 27,662 bathers
and 36,677 washers; in the second year there were 84,584
bathers and washers. This, though the first establishment
was the kind in which the majority of the poor
very small having been previously started, and with
much success, in Liverpool, though without the knowledge of the
London Committee. The Glasshouse Yard establish-
ment was owed entirely to its founder, the Rev. Dr. Trench;
there was nothing extrinsic to render it attractive. It was placed
one of the worst spots in the metropolis; the building itself
was as little suited to the purpose as any building well could be;
the accommodation was of the most ordinary kind.
Yet it at once proved—if proof were needed—that the
poorest in that wretched neighbourhood would gladly be clean
when the means were attainable. In August 1846, a second,
and much superior establishment, was opened in George
Street, Eaton Square; a plot of ground having been liberally
offered by the New River Company, near one of their reservoirs,
with the additional advantage of a free supply of water
for the first six months. In the first year there were here
some 113,000 bathers and 20,000 washers. This establish-
ment, in which the baths are more varied in price than
elsewhere, still flourishes.

The establishment third in point of date was, however,
the first in importance and in the value of the consequences
which resulted from it. In this the committee first fairly
developed their views. Although the building of Glasshouse
Yard was opened gratuitously, it had been desired that
the institution should as soon as practicable be rendered self-
sustaining by means of a small charge to each person who
used it. The committee hoped too, to see the system ex-
dended through the metropolis; and we do not see
that nothing would so effectually and speedily further that
object as to be able to show a Model Establishment, which,
while it contained all the conveniences and appliances which
those who availed themselves of it could desire, should be in
itself all that science, combined with practical skill, could
effect in the economy, suitableness, and completeness of its arrangements. Accordingly, architects and others were invited to tender estimates for the buildings, and the information which could be obtained was collected.

The Model Establishment was then erected on a site which had been purchased in Goulston Square, Whitechapel, a very poor and crowded neighbourhood, but of ready access. The building is, in fact, almost entirely novel, being a very large original outlay, and many changes have been subsequently made; but as a whole they had been so carefully considered, and were so judiciously designed by Mr. Prichard Baily, the architect, that a principal alteration has, indeed, been found necessary; in a recent Report of the Committee, we are told that the general arrangements and mode of construction have been almost universally followed in London and the country.

In fact, then, these new arrangements are pretty much alike. The exterior is usually a plain brick building, with stone quoins and dressings; having a basement, and, in front, a story above it, with a lofty square ventilating and chimney-shaft, somewhat like a campanile in appearance. A brief sketch of the interior of any one will serve to give a general conception of all, it being understood that there are differences of detail in each.

The baths for males and females are on opposite sides of the building. As the men are by the washing-room, in some others by the plunging-baths. In both sides are first and second class baths. The apartment in which these are placed is spacious and lofty, covered by an open roof, and lighted in the day by ample skylights, by gas-lighting at night. The bathing-room is equipped with some of the most costly apparatus in the bathroom, and the water is carried off by water-pipes: an opening at the front of the machine shows when the water ceases to flow, and consequently the 'wringing' is completed, and the pressure of a lever at once stops the machine, and also mangles the clothes. The machine is then, by turning the tap, and without moving from her standing-place. The water in the boiler is made to boil by the admission of steam into it, which, as we said, the washer can do whenever she pleases. The ventilation is so arranged that the steam from each compartment is once drawn upward and carried off to the great ventilating shaft.

The Wringing-Machine is in effect a sort of wide but shallow colander, the sides, instead of the bottom being closed, having two long, slender handles, which are placed in such a manner that the meshes are about a quarter of an inch apart. When the wet clothes are put in this, it is set in rapid motion by a handle which works a few connecting wheels; the clothes at once by centrifugal force arrange themselves around the sides, and as fast as the mangle is filled the last cloth is removed, and carried off by water-pipes: an opening at the front of the machine shows when the water ceases to flow, and consequently the 'wringing' is completed, and then the pressure of a lever at once stops the machine, and also mangles the clothes of the washers. Each division of the chamber contains a clothes-horse or maid, one being allowed to each washer. In ten minutes, or a quarter of an hour, the clothes, unless very heavy or numerous, are quite dry. The committee have published a table in their Report to show the rapidity with which the drying is accomplished. Some of the results are curious. We may take a single instance as an illustration of the processes we have been following. A large dirty dress, weighing 9 lbs. 1 oz., on being washed, they weighed 94 lbs. 14 oz.; after leaving the wringing-machine, 12 lbs. 3 oz.; after being dried, 8 lbs. 12 oz. These blankets took twenty-five minutes to dry, at a temperature of 210°. In all other cases the washerwomen, a quick eye and quick hands, can do as well when taken from the drying-machine contained decidedly less moisture than they did when they were received for the wash. To show the 'satisfactory working of the drying-chamber at the Model Establishment, and also its great advantage in the economy of time, trouble, and expense, both to those of the labouring classes who resort to it,' the committee give a return of the articles dried there in one week ending January 24, 1865. It is too full for us to copy; but we may state that the number of articles of all kinds, from counterpanes, jackets, and trousers, down to shirts and stockings, was 36,844, belonging to 1373 washers, who occupied 2998 hours in washing, drying, and ironing them; and that the drying consumed only 282 bushels of coke, which cost under 4d.

In most of the establishments there is only one class of washers; but in some there are both first and second classes, the difference being that the first class have a somewhat larger compartment allotted to each washer, and a third or roomy place; and as the charge for the use of the establishment has described is now generally 1 1/2d. an hour, though in a few places it is only 1d. an hour. Where there are both classes, the charge is 2 1/2d. an hour first-class, and 1 1/4d. second. Some establishments have a second and third class; and the number of washing compartments varies, of course, according to the size of the establishment; at Goulston Square there are 84 of them, at St. Martin's 56. The average time occupied by each washer at the Model Establishment is two hours and a half; and this is the general average time in London; in some country towns it differs considerably. In
At this time he was alike opposed to Kossuth, with whom however he afterwards allied himself. When, in consequence of the events of March 1848, the Archduke Stephen was created Palatine of Hungary, Count Louis, an old friend of Stephen's, was named interior minister. It was in this capacity to maintain the political union between Austria and Hungary. After the invasion of Jellachich, and some fruitless negotiations with Austria, he resigned his functions on September 26, but on the next day he was commissioned to form a new ministry, but this effort failed. After the dissolution of the Diet, and the murder of Count Lambert, he repaired to Vienna to endeavour to prevent the ill-effects of this crime, and it is possible to form a new administration which was induced to request him to undertake necessary conveniences at a charge not exceeding 3d. for two hours. Baths and wash-houses of a higher class are to be charged as the council and commissioners may think fit. The baths and wash-houses “for the labouring classes” in any such establishment, must be not less than twice the number of those of any higher class. The Act at once gave the system a firm standing; and both brothels and parishes have availed themselves of its powers to a considerable extent. Of course, it is not always easy to persuade vestrymen to permit an addition to be made to their parochial rates for a purpose that does not promise advantage to themselves; but as it has become year by year more evident that these institutions may be made self-supporting, and in the event of a charge being made there is an increasing readiness to find them. In London and the suburbs, besides the Model Establishment in Soho Square, and that in George Street, Hampstead—new establishments are being provided in various parts of which are fitted up in an extremely complete manner, while all are well attended by both washers and bathers. Manchester and Liverpool have each several baths and wash-houses, and almost every other large town throughout the country is either providing or means to be provided with similar establishments; and the example has been followed by several of the smaller towns. Nor have the good effects of the movement been confined to this country. The progress of the appearance of a number of baths and wash-houses for the Labouring Classes, were at the end of 1853, to state in the Report before quoted, that the governments of France, Norway, and Belgium, the municipality of Venice, and the authorities at Hamburg, Paris, Munich, Amsterdam, Lisbon, and New York, had applied for, and been furnished with information on the subject; and in some of these countries the example of England has been followed in providing similar establishments for the labouring classes.

It is true that the institution has become firmly established. In London alone, the bathers number little short of two millions a year; while the washers exceed half a million. The constantly increasing number of bathers and washers shows that the demand is much exceeded in the growth of the population. The experience of twelve years has proved that, with proper attention and economy, the establishments may be rendered self-supporting; and the observations of all who have watched them in particular localities, vouch for their beneficial influences. The point in which they appear to have failed, is in reaching the very poorest. That portion of the community for whom the institution was primarily intended, seems to have been scarcely touched by it. Every class that has availed themselves of the baths, of a class above the poorest. The most profitable section of the establishment is found to be the “first class.” Whether making themselves of the hint, the managers of these establishments might not, by furnishing a yet higher class bath (though still at a moderate price), provide the means by which they might support one of a cheaper kind than they have at present been able to afford, and so extend the benefits of the system both upwards and downwards, is a question proper deserving of more attention than it has hitherto received.

BATHYANI, COUNT LOUIS, was born at Presburg in 1809. At the age of sixteen he entered the Austrian army as a cadet, and was stationed at Venice. He subsequently travelled through the country after the fall of the Austrian Empire, and in the winter of 1831-1832 visited Constantinople. On his return to his native country, he became at once a leader on the liberal side, a distinguished orator, and a favourite with the public. From 1839 to 1844 he opposed openly the Austrian chancellor Count Kossuth, in favour of Hungarian commerce and industry.
BEAUFORT, rear-admiral Sir Francis, K.C.B., F.R.S., &c., late hydrographer to the Admiralty, is the son of the Rev. Daniel Anger, Fellow of New College, county of Meath, Ireland, and author of a Map of Ireland, published with a memoir, in 1792, as well as of some theological publications. Francis Beaufort entered the navy, in June 1780, as a midshipman in the Channel. He was made midshipman in June 1790, and while holding that rank saw much active service, assisting among other duties in the capture of several vessels. In May 1796 he was created lieutenant, and whilst acting as master of the Phaeton, was by the hawser under his orders a barge and two cutters, boarded and took the San Joseph, a Spanish polacre-rigged ship of 14 guns and 66 men, which lay moored under the protection of five guns of the fortress of Sanlúcar, near Malaga, supported by a frigate. Lieutenant Beaufort in this brilliant affair received a wound in his head, and several slugs in his body and left arm; but was recompensed by obtaining, as a recognition of his skill and courage, a commander's commission. During a cessation from service after, he was engaged from November 1800 to June 1804 in superintending the construction of a line of telegraphs between Dublin and Galway. In June 1805 he proceeded as commander of the Woolwich 44 guns, to the East Indies, and returned thence to Plata, where he remained during the campaign of 1807, a very valuable survey. He was afterwards stationed at the Cape of Good Hope, and in the Mediterranean. In May 1809 he was appointed to the command of the Melpomene, and the following year was made the rank of Post Captain to the command of the Frederickstein frigate. During 1811-1812, he was engaged in making a minute survey of the coast of Karamania in Asia Minor, but was compelled in the latter year to return home in consequence of wounds inflicted on him by a fanatic Musulman by his men.

In the course of these services Captain Beaufort had obtained a very high rank, as a scientific as well as a brave seaman, and equally so as a hydrographer and geographer. He was very closely connected to Admiral to devote himself to working out and embodying in a series of charts, the results of his various surveys. Among other charts constructed by him were one of the Archipelago, three of the Black Sea, including the coast of Asia, and seven of Karamania, these last being accompanied with a 'Memoir of a Survey of the Coast of Karamania in 1811 and 1812.' In 1817 he published in 8vo, a fuller and more elaborate work on the same subject: 'Karamania; or a Brief Description of the South Coast of Asia Minor, and of the Remains of Antiquity, &c., with plans and engravings.' His labours and scientific merits found their appropriate reward in his elevation, in July 1835, to the post of Hydrographer to the Admiralty, to which important office he imparted new honours, and to which his scientific duties, which he continued to hold till he retired full of years and honours on the 30th of January 1855, having very nearly completed his 68th year of service. He was succeeded by Captain Washington Reid. Admiral Beaufort died in Dec. 1857. In April 1835, Captain Beaufort was appointed Commissioner for Inquiry into the Laws, &c., affecting Pilot; and in January 1845 a Commissioner for Inquiry into the Harbours, Shores, and Rivers of the United Kingdom. He was created Rear-Admiral, Oct. 1, 1846.

Admiral Beaufort, besides his memoirs on the coast of Karamania, &c., contributed papers to the Geographical and other learned societies; and the important collection of Manuscripts and the Diffusion of Useful Knowledge was executed under his supervision. He was elected Fellow of the Royal Society in June 1814; he was also a Member of the Council of the Geographical Society, a Fellow of the Royal Astronomical Society, a Corresponding Member of the Institute of France, &c., and was placed amongst the members of the Colours 74.

BEAZLEY, Samuel, architect and playwright, was the son of a surveyor in Parliament-street, Westminster, where he was born in 1766. In early life Mr. Beazley served as a volunteer, and went on his adventures in the Peninsula and set up for himself as a wholesale romancer. Mr. Beazley's chief claim to remembrance as an architect arises from the fact of his having erected a larger number of theatres than any other contemporary architect in this country. He also worked in Europe, where he gave the names of Pont-Claro and Pont-Granville. After this voyage Captain Beechey remained un-
employed for some time, as his health had suffered; but he occupied himself in preparing and publishing accounts of the various voyages he had made. In 1835, the year of his return, he appeared 'Proceedings of the Expedition to explore the Northern Coast of Africa, from Tripoli eastward, in 1831 and 1832'; the 'Voyage to the North Pole' followed; in 1831 appeared the 'Narrative of a Voyage to the Pacific and Behring's Strait'; succeeded by the Botany and Zoology of the same voyage, in two expensive quarto volumes. He had also been employed between 1839 and 1850 in surveying the coasts of South America and Ireland for the Admiralty of the Blue. He died November 26, 1856.

BELLLOT, JOSEPH RENE', was born at Paris, in March 1806. His father, who was in humble circumstances, removed to St. Nazaire when Joseph was five years old. Joseph was placed in the elementary school of that city, and so favourably a report was made by his schoolmaster at the close of his term of instruction, that the municipality at once granted him a bursary at the College of Rochefort. Here his progress was so steady that he was graduated at the end of his 16th year, and proceeded to the naval school at Brest, the municipality of Rochefort continued to contribute a moiety of the expense. He was two years at the naval school, and on quitting it it took rank as a 'lieutenant', but after six months in port, he received his commission as 'lieutenant de marine' on board the corvette Berceau, bound for the Isle of Bourbon. It is worthy of remark, as characteristic of Bellot's excellent disposition, that, before leaving France, out of his slender salary be assigned to his family the sum of 20 francs a month.

Bellot remained abroad somewhat over three years, returning home in November 1847. During this time, while steadily pursuing his private studies, he had, by the diligent discharge of his duties, the acquiescence and approbation of his superior officers. M. Romain Desfosses, the commodore, to whom Bellot had acted as aide-de-camp, in his official despatch to the minister of marine, pronounced Bellot to be "the most distinguished officer of the station, ... in every respect superior to his age and position." Distinguished merit in a young officer is seldom neglected by the French government. For his conduct and bravery in the expedition against Tamatave, Madagascar, in July 1846, in which he had distinguished himself, he was appointed an 'adjutant of the first class', and, though under twenty, created a Chevalier of the Legion of Honour; and now on returning home with the high commendation of M. Desfosses, he was raised to the rank of Sub-Lieutenant.

This raised his character, but not his rank. Bellot sailed in the corvette Triomphant to South America, where he remained for about two years. His conduct here affords a fine lesson for the young officer, whatever service he may be in, and to what part of the world he may belong. His strictly professional duties, and they were very onerous, were most carefully and sedulously performed, and he obtained, as before, the warmest commendations from his superiors. But his own time was carefully husbanded and admirably employed. He not only extended his knowledge, especially in hydrography and geography, but taught himself to speak English, Spanish, and German fluently; and withal gave up much time and thought to what he had to come to regard as an important part of an officer's duties, that of learning the languages of the nations he did carry this, that, both here and on the African station, his biographer informs us, "he gave on board the vessel a course of lectures on geometry and navigation for all those seamen who, being intended for masters of trading vessels, would have to pass on their return the examination in theory and practice required by the rules of the marine."

Bellot's thoughts were now turned to a new sphere of operations. The search after Sir John Franklin and his party is one of the most important themes of the day. The nation desires that of Gar-Fish. It was placed by Linnaeus in the genus Ence, and being an inhabitant of the seas, it got the name of Sea-Fish. From the fact of its leaving the deep water in spring to deposit its eggs near the shore in the months of April and May, and this preceding the mackerel in their annual visit to shallow water for the same purpose, it has received the name of Mackeral-Guide. Its other English names, according to Yarrell, are Greenland, Horn-Fish, Sea-Fish, or Striped Salt-Water Fish. The length of this fish is about 24 inches. It has elongated jaws, beset with numerous minute teeth. The eye is large. The body is uniform in depth to the anal fin, thence tapering to the tail. The dorsal and anal fins begin and end near on the same level. The lateral line terminates on the tail, and the long external rays are nearly as long as those of the centre. The upper part of the head and back is of a dark
greenish blue; the sides and belly are silvery white; the pectoral, ventral, and anal fins white. This fish is taken off the coast of Norway during the mackerel season, and Dr. Johnston says it is not unfreqently called a Sword-Fish. It is taken also on the Devonshire and Cornish coasts. The fish are brought into the London markets in the spring, and come in quantities. The flesh is considered of excellent quality, but it is difficult. Great numbers are said to be caught off the coast of Holland, but they are only used there as bait. Mr. Couch says of the Gar-Fish, that it "swims near the surface at all distances from land, and is seen not uncommonly at the surface of the water. Its gill rakers are of such a length that it will for a long time play about a flowing stream, and leap over it many times in succession. When it has taken the hook it mounts to the surface, often before the fisherman has felt the bite; and then with its slender body has great difficulty in tearing the fish from the hooks." The sword of this fish is used for a weapon.

In the Ionian Islands, according to Mr. Tonna, it is caught by attaching several lines with floats to a raft. In this way a large number are taken in a very short time. Specimens of this fish have been exhibited in the Aquarium of the Zoological Society, in the Gardens, Regent's Park.

There are several other species, some of which are said to attain the length of 23 feet, and to bite very severely. The Whale gar is the largest of these. The flesh generally is wholesome. (Yearrell, British Fishes: Cuvier, Reine du Animal.)

BENUTS. The fruit of Morinda pterogyposperma, from which Ben-Oil, much used in perfumery, is obtained.

BENICASAI, a genus of plants named by Savi, in honour of Count Benicassai, an Italian nobleman. It belongs to the order Cucurbitaceae, and has but one species, B. cerifera. The fruit is described as covered with hairs and a glistening bloom. It grows in the East Indies. Lindsley, in the 'Vegetable Kingdom,' describes it as identical with Cucurbita pepo. Ainslie says that in the East it is presented at every native marriage feast, and is supposed to insure prosperity to the married pair.

BENTINCK, Lord William George Frederick CAVENDISH, commonly known as Lord George Bentinck, was the third son of William Henry, fourth duke of Portland, by Henrietta, daughter and co-heiress of Major-General Scott, was married to the late Lady Canning. He was born on February 27, 1802, and though only a younger son, inherited a fortune from his mother that placed him above the necessity of adopting a profession. He however entered the army, and gradually attained distinction. He was wounded at Waterloo, and the profound peace that followed was not calculated to open the way to any ambitious aspirations in that direction. He therefore, when his uncle Canning became secretary for foreign affairs in 1826, became his private secretary, for which he displayed extraordinary capacity, was treated with great cordiality, had unbounded confidence reposed in him, and it was thought a brilliant political career was opening before him. In 1827, while his uncle was first lord of the treasury, he entered parliament as member for the Aylesbury election, and the close of his life. He however did not distinguish himself in parliament at this time, except by a very sedulous attendance: he spoke very seldom, and then not well; but he voted. He was a supporter of what were called Whigs. He voted for Catholic Emancipation, but was not very warm in its favour. On Canning's death in 1827, Lord George gave an independent support (this means opposing them occasionally) to Lord Goderich's cabinet, in which his father was president of the council, but he declined voting for the Motion of Lord Ebrington's motion that defeated the Wellington cabinet. He however continued to support Lord Grey's government till the secession of Lord Ripon, Sir James Graham, and Lord Stanley (now Earl of Derby), to the latter of whom he was strongly united by the consequence of political opinions and the similarity of pursuits; both being strongly attached to the turf. On the accession of Sir Robert Peel in December 1834, he formed one of the small party nicknamed the bureaucrats, and which he at first supported; but when Peel moved a failure of confidence he retired. He himself repaired to Lisbon, where an attempt was made on his life; the ball aimed at him was arrested by a piece of money in his pocket.

On the commencement of the revolution in 1848, Bent at first attempted to organize the insurrection at Vienna, and afterwards joined himself to the Hungarian party. Charged with the command of an army to oppose the Austrians on the side of Transylvania, he at first experienced some checks, but at length, with the aid of the western states, he took Cracow, and repulsed the Austrian army, though joined by that of Russia, called to its assistance in the previous February. He also compelled the Austrian general, Puchez, to abandon the Banat and Wallachia. The Austrians then rallied; in attempting in vain to excite the Wallachians and Moldavians to rise, he was attacked and defeated at SEGEVAR by a greatly superior force under Lüders, the Russian general. He however succeeded in re-assembling his forces, and on August 8th he took part in the battle of Temesvár, in which the Austrian army was the first timeSelections from The Times.
of Sir Robert Peel's supporters; and when in 1846 he wholly repealed the Corn Laws, Lord George went into the most violent agitation. For some months he kept Lord George abashed but little of his animosity, although he opposed the Whig free-traders who had succeeded him. The country party, as it was termed, had been taken by surprise, and knew not where to look for a leader. At length they selected Sir Robert Peel for their candidate; but, having accepted it, he threw himself into the part with his accustomed energy in whatever he undertook. He commenced studying statistics, spoke on every possible occasion, he impeded the administration in their measures. But though clever, ardent, indefatigable, and too often unscrupulous, free-trade continued its march in spite of his efforts, seconded by those of his principal ally, Mr. B. Disraeli. He had during all these years kept up his attention to racing and race-horses, declaring on one occasion that the winning of the Derby was the "blue-ribbon" of the turf. On the prerogation of the house in August 1846, he retired to Welbeck Abbey for relaxation; he however attended Doncaster races four times in one week, at which a race of his own breeding won the St. Leger stakes, to his great gratification.

On September 21 he left the house on foot soon after four o'clock in the afternoon, to visit Lord Manvers, at Thoroton. He was met there by the footmen at an appointed place. He appeared not; the servants became alarmed; search was made for him; but it was not till eleven at night that he was found quite dead, lying on a footpath in a meadow about a mile from the house. At the coroner's inquest it was stated in evidence that he had been spasms of the heart. A lengthy life of Lord George has been written by his friend and follower, Mr. B. Disraeli, in *Svo, 1851. (Gentlemen's Magazine; Miss Martinus, History of the Thirty Years' Peace; B. Disraeli, Life of Lord George Bentinck."

BERANGER, PIERRE JEAN DE, was born in Paris, August 19, 1790, of humble parentage, and in his earliest years was brought up by his grandfather, a tailor. He witnessed the taking of the Bastille, in 1789, and was then removed to the care of an aunt, who kept an inn at Peronne. Here he first learnt to read. At fourteen he was apprenticed to a printer in Peronne. Somewhat later he attended a printing office, and in 1805 he left Paris, returned to his father at Paris, and having attended some theatrical representations, resolved to attempt a comedy, and produced "Les Hermaphrodites." At eighteen he projected the work of a novel, but was arrested by the prosecutions of the time; in 1812 he composed the the "Theodore," and was in 1813 published in his work edited by M. Ferrotin and published in 1834. These performances did not improve his fortunes; and, reduced to great distress, he thought of proceeding to Egypt, where Bonaparte was then, and whose first successes had excited extravagant visions of glory and prosperity among the French population. The return, however, of some members of the expedition dispirited Béranger's dream, and he remained in Paris. It was at this period, when suffering from his disappointed hopes, and even actual indigence, that he seems to have resolved to be gay if he could not be happy, and he produced his "Roger Bontemple," "Le Roi d'Yvetot," and "La Lorraine," all of which were not immediately successful; but in 1830 he sent some of his poems to Lucien Bonaparte, who promised to ameliorate his situation. Lucien was suddenly called to Rome. Béranger thought himself forgotten; when a letter came from Lucien, asking him for his income as a member accepted the situation. He next obtained some employment as an editor, and in 1809 was appointed a clerk in the secretary's department of the Academy. His songs were now beginning popular in every quarter. During the 'hundred days' of Bonaparte, Béranger was appointed a member of the censor. In 1813, when he published his first collection of songs, which were popular throughout France, he was informed that it would occasion his dismissal from the office he held in the Academy. He wavered not, and was retained; but in 1821, when the second collection was published, he was at once discharged. He wrote more and more poignant satires upon the government; he was prosecuted, and was sentenced to the châtelet. But in 1825 he published his third collection, and in 1826 his fourth. For this last publication he was again prosecuted, and was condemned to nine months' imprisonment and a fine of 10,000 francs. Confined more strictly in the prison of La Force, he employed himself in the attacks on the faults and follies of the government, and these remarkable lyrics aided not a little in accelerating the fall of the Bourbons.

In 1830 the revolution of July would have acted favourably for Béranger's fortunes if he would have given up his beloved independence. He says, 'I was treated as with one of the great powers; ' "nearly all my friends have become ministers; "unfortunately I have no love of sycophants, and my political works have been the cause of this." Béranger was convinced that France was not fitted at this time for a republican government, and he supported the establishment of a limited monarchy. In 1833 he published his fifth and last collection of songs, consisting of some of his most striking pieces. After the revolution in 1848 he was elected in April of that year a representative of the Department of the Seine in the Constituent Assembly, by more than 200,000 votes; but in May he sent in his resignation. It was unanimously rejected; but a week afterwards he renewed it, and it was accepted.

Béranger continued to write, but did not publish. He was known to have a large collection of songs, and he employed himself also with a 'Biographie' of himself and his contemporaries. He lived in a country villa in the suburbs of Paris, country, living quietly in retirement, and enjoying the society of a few friends. He died in Paris, July 16, 1857, and was buried on the following day in the cemetery of Père la Chaise, at the expense of the French government. Soon after his death Madame Colet published "Forty-five Letters by Béranger, and Details concerning his Life" (Quaronce-Quinze Lettres, &c.). In October, 1857, M. Lapointe published "Memoirs of Béranger" (Mémoires, &c.; in November appeared "Le Roi d'Yvetot" (Editors, &c.;); and in December was published "My Biography," by P. J. de Béranger ('Ma Biographie,' &c.). The songs of Béranger have deservedly attained a high reputation, not only in France but throughout Europe. One charm is their complete nationalitv. The delicate wit, the subtle satire, the indignant denunciation, the vivid and correct pictures, the frequent comicality of situation—are all truly and exclusively French; and so are the faults that are so frequently encountered in the same vein of the French language. It is marvellous, and in the most difficult rhythms the words always seem to drop naturally into their places; but this result, as he states in his 'Biographie,' was attained by him only with great labour.

The whole work of Béranger is very remarkable. He had become a real power in the state, under the first Napoleon. Although he felt that there was no hope for the national freedom of his country while that despotism endured, he had a sincere admiration of the emperor's genius. Consequently there were no personal attacks in his early songs, and when a little gentle railing upon externals was ventured—as in "Le Roi d'Yvetot" and 'Le Sénateur'—it was laughed at and applauded even at court. Béranger is considered by his countrymen as a religious poet: this is not the impression which an Englishman would receive. But he certainly does not shock by impurity, however he may offend by levity and want of reverence. The songs for which he was prosecuted were not attacks on religion, but on its false assumption. He praised and indicted both in his "Roi d'Yvetot," and "Le Sénateur." Béranger has little resemblance to our own song-writers. He has none of the deep passionate love depicted by Burns. He never contemplates the happiness of the fashions that jar on English feelings of delicacy. The passion he describes is indeed rather that which has become very common to the French, i.e., the contrast to our patriotic singer, Dibdin, is also striking. Dibdin holds out few incentives to the sailors he addresses beyond a sense of duty, prize-money, a picture of domestic happiness with their Nancys, and Greenwich Hospital. Such encouragements find no place with Béranger. The
glory of France is in the most prominent inducement to flight and to die. To our other lyrical poet, Moore, he has somehow what more resemblance.

**BERCHEMA**, a genus of plants belonging to the natural order Crambeaceae. Two species, *B. colchica* and *B. linifolia*, are used in medicine.

**WILLIAM CARR, VISCONTI**, the natural son of the first Marquis of Waterford, was born on October 2, 1768. He entered the army early, and while serving in Nova Scotia lost the sight of an eye from the accident of his brother officer. In 1776 he served at Toulon, at Bastia, at Calvi, and in the West Indies under Abercromby, and in Egypt under Baird. In 1806, having attained the rank of brigadier-general, he commanded the land forces in the expedition against Buenos Ayres, and was taken prisoner with his command and escaped shortly afterwards. In 1807 he commanded the force which obtained possession of Madeira. In 1808 he arrived in Portugal with the English forces, and to him was confided the organisation of the Portuguese army, including the militia. This he effected so completely that the Portuguese troops, throughout the Peninsular war, showed themselves worthy of fighting by the side of their British allies. On May 6, 1811, he invested the fortress at Badajoz, and, after a series of brilliant actions, the battalions of Salamanca, in 1812, he was wounded. He then commanded a division under Wellington, and took a distinguished share in the battles of Vitoria and Bayonne. On the 10th of April 1814, he attacked and carried the heights before Toulouse, and bravely asserted that he had been created a Portuguese field-marshal, Duke of Elvas, and Marquis of Santo Campo; and he was now created a British peer by the title of Baron Beresford. In the same year (1814) he was sent on a mission to Brazil: he returned in 1815; and after a short visit to Portugal, he repaired to Brazil again. On his return he resumed the command of the army of Portugal, at the request of the Portuguese government, but resigned it at the end of a few years, not approving of the measures then being made to establish a constitutional government. On his return to England in 1833 he was created Viscount Beresford. From 1828 to 1830 he was master-general of the ordnance. He continued to take an active part in politics, being strongly attached to the Tory party; and in 1826, in consequence of assisting in forwarding English troops for the support of Don Miguel, he was deprived of his rank as Portuguese field-marshall. In 1828 he married Louisa, his cousin, the daughter of the archbishop of Tuam, and the wealthy widow of Thomas Hope the banker, but left no issue. He died at Bedegbury Park, Kent, on January 8, 1844. At the time of his death he was governor of the Royal Military Academy at Woolwich, and curator of the island of Jersey.

**BERGERA**, genus of plants belonging to the natural order Amentiferae. *B. Königi* possesses stomatice and tonic properties, and an infusion of the leaves is used against vomiting. The green leaves are used raw in dysentery; the bark of the tree is used in the treatment of eraw.

**BERKELEY, a genus of Distomataceae, named by Greville, in honour of the Rev. M. J. Berkeley, distinguished for his researches in cryptogamic botany. It belongs to the suborder Convolvulales, and is characterised by having linear frustules included within tabular substationed cuneate siliceous filaments, which are free at one extremity, but have the other immersed in a gelatinous tubercle. *B. fragilis* is found parasitic on *Zoster marina*, and some of the smaller marine Algae on the coast of the Adriatic at Trieste.

**BERMONDSLEY. [SURREY.]**

**BERTHOLETTA. [MATERIA MEDICA, &c. 2.]**

**BERZELIUS (or BENZEL), JONS JACOB, one of the most distinguished of modern chemists, was born August 20th, 1779, at Wäsersunda, a village near Linköping, in East Gothland. Beyond the fact that he received the education of his learning from his father, who was parish schoolmaster, we have not any information of his early life. In 1799 he married Anna Charlotta, who died while his son was young and left him now nothing of his early years. At the age of seventeen the youth entered on the study of medicine at the university of Upsal, and attended the dule lectures on chemistry delivered by Albrecht. Shortly after that time he commenced to render scientific instruction clear to the mind, that Berzelius had to discover and investigate facts and draw conclusions for himself, and soon became remarkable for his diligence and discernment. At an instance of the way in which he was initiated into chemical manipulation, he used laughingly to relate in after life:—"Affelius first gave me sulphate of iron to calcine in a crucible, for the preparation of colorathor. "Any one may do work of this kind," I replied; and if this be the way you are to teach me, I may as well go home. I have little patience to sit for three hours together!" "Your next preparation shall be more difficult." On the next occasion I got cream of tartar to burn, in order to make pottas; which so disgusted me, that I vowed never to ask for any further employment from him. But he still continued to instruct me, notwithstanding his vow, and soon frequented the laboratory every day, although by the rules pupils were entitled to admission but once a week, his masters offering no opposition. Ekeberg was, however, vexed at times that the young chemist seemed to have no proper attention to his duties; and he said to himself: "I preferred," said Berzelius, "to endeavour to instruct myself by reading, meditating, and experimenting, rather than question men without experience, who gave me replies, if not evasive, at least very little satisfactory on the subject of phenomena which they had never observed." In 1798, after two years' study, he left Upsal, and engaged himself as assistant to the physician-superintendent of the mineral springs at Medevi, a watering-place much resorted to by the nobility. Here he soon became nearly as well known for his chemical researches as for his literary studies. He analysed the waters, and in conjunction with Ekeberg published a paper embodying the results. This was the first of the long series of papers that remain to illustrate his fame. In 1804 Berzelius returned to Upsal, and took his degree of doctor of medicine, and so soon as he had found some employment for him, his Investigations on the Effects of Galvanism on Organised Bodies, a work which exhibits much of his sagacious insight and painstaking. Davy, who was born in the same year with the illustrious Swede, had made known his experiments; and when Berzelius, taking up the subject, then worked together with Davy, men, materially widened his applications. His growing reputation gained for him, on his going to reside in Stockholm in 1805, the post of assistant to Sparmann, professor of chemistry, with the benefit of an allowance which he could use only during his second voyage of discovery. The amulets were so scanty that Berzelius had at times to practise medicine to eke out his resources. In 1806 he succeeded to the chair, and in the same year, jointly with Hisinger, he commenced the "Aphthander or Fynik, Kemi, och Mineralogie," to which during the twelve years of its existence, he contributed forty-seven original papers. This periodical was at once translated into German, and subsequently into French, and generally prized for its trustworthy elucidation of chemical principles. This however was but a small part of what Berzelius undertook: he set to work to revise the labours of his predecessors, accepting no conclusion that did not admit of the clearest demonstration. His skill as an analyst is described as "extraordinary" by Dalton; and when Dalton published his views he, by innumerable analyses, established the laws which regulate chemical combinations, and reduced them to a form so simple as to give them a twofold value. "When I was on the point of becoming well acquainted with the eminent foreign savant," it became possible to control the results of analyses—even to foresee a great number of combinations then unknown—and to carry into every operation an accuracy previously thought altogether unattainable." By his elaborate examination of solutions in the salts and going through the whole range of elements, including the products of organised existence, Berzelius anticipated Dalton in some of his conclusions, and afterwards found a perfect system of nomenclature for the elements of the Manchester philosopher. His knowledge of the laws of atomic combinations enabled him to elucidate the nature of minerals, and to show at the same time, by the composition of the minerals, the universality of the laws. He helped indeed to bring the atomic theory to power and to swell the might of science. He framed moreover an electro-chemical theory, and published "Lectures on Animal Chemistry," a work filled with rare proofs of original research and clear perceptions on a subject of science then least understood. On the publication of the first volume of the Journal of Chemical Literature, which the following year he was admitted a member of the Royal Academy of Sciences of Stockholm. In 1810, being then at the age of thirty-one, he was elected President of the Academy; a
striking proof of the estimation in which he was held by his colleagues.

Bessel was called to England in 1819, and while here learned how prelections could be made really interesting as well as instructive by attending Dr. Marriott's lectures at Guy's Hospital.

In conjunction with Dr. Marriott he wrote a paper entitled 'Experiments on the Alcohol of Sulphur, or Sulphuric Acid,' which was published in the Philosophical Transactions for 1813; and in the same year he was elected a foreign member of the Royal Society.

On his return to Stockhelm Besselius at once changed his style of lecturing, and with the happiest results. His dry manner was changed into a more genial style, of which he greatly multiplied the number suitable for public exhibition by his quick imagination. Men whose names have since been famous attended his teaching. In 1815 he received the Regius Chair of Natural Philosophy and Mathematics at the University of Gottingen, and in 1818 he was chosen perpetual Secretary of the Academy, which distinguished post he held for the rest of his life. In the same year, at the coronation of Charles John, he was emboldened with permission, contrary to custom, to remain, to retain his name. In 1821, at the instance of the Academy, he commenced that series of annual reports on the progress of chemistry and physics, which, while contributing materially to the advancement of those sciences, confirmed and beautified their reputation. He was one of the few who did not change him with jealousy or envy, because of his intolerance of unsubstantiated theories. No theory was ever accepted or started by him that was not supported by a solid basis of fact. If 'too cautious,' as was often said, he studied but the foundations of science; and if it jealous, it was for chemistry, and not for himself. Regarding himself as a vidette ever on duty, he warned and alarmed whenever the occasion required, and confined in integrity, delivered his opinions with unqualified freedom. So faithful a censor will not be easily escaped.

In the hands of Besselius the blowpipe became a most important instrument in the analysis of inorganic substances. A translation of his treatise on the subject appeared in English under the title of A Treatise on the Blowpipe and its Application to the Analysis and the Examination of Minerals. There was a scarcely a question that he did not bring to the test of experiment, and reduce to its proper place in science, as may be seen in his great work 'Lehrbuch der Chemie,' which has gone through six editions, and as many translations. The last was published at Paris, in six volumes, octavo, in 1845-1850.

In 1833 Besselius resigned the professorship which he had held for twenty years, and returned to Germany, where he enjoyed the highest public estimation. He married about this time, and on the day of his wedding the king wrote to confer on him the dignity of 'Freiherr,' or Baron, observing that, "Sweden and the world were the debtors of a man whose entire life had been devoted to the benefit of his native country." Subsequently he had the further honour of receiving the Grand Cross of the Royal Swedish order of the Polar Star. The directors of the Swedish iron-works awarded him a pension, in acknowledgment of his eminent services to their branch of industry. And in 1836 the Royal Society of London showed their sense of his merits by giving him their Copley Medal.

The life of Besselius flowed on in a tranquil current. He enjoyed all the honours his native land could give, had the satisfaction of seeing his name enrolled among the members of nearly all the scientific societies of the world, more than 100, and of knowing that foreign governments recognised his worth. As he approached the age of fifty his sight began to fail, and his memory to lose somewhat of its power. Infirmities now increased on the philosopher, whose health had never been robust. He was seized with paralysis of the lower extremities; but retained the serenity of his mind till death approached, as one who said, after slow, sighing, "a messenger who regretted his errand," closed his career on the 1st of August, 1848.

His death was felt as a national calamity, and the scientific societies of his native land wore mourning for two months in respect for his memory.

Besselius died at Stockhelm at Midd. on the 32nd of July 1784. His father was a civil officer (justizrah) under the Prussian government; his mother a dervyman's daughter; and there being a family of nine children to rear, they received only an ordinary education. Among his earliest manifestations was a dislike of classical literature, and a love for arithmetic. His quickness in calculation led to his being rated at the age of fifteen as clerk in a mercantile house at Hamburg. He then went to sea, and one of his main duties that lay immediately before him, whatever it might be; and this remained his especial characteristic. The hope of being offered the post of supercargo on a foreign voyage was then his stimulus; and to qualify himself for this responsible office he began to take up the rudiments of navigation and surveying. Besselius would have been a great mathematician, but for his early life thus engaged. On his return from his last voyage he had not yet completed his 18th year. He returned to Hamburg, and was employed by a merchant in the ordinary business of his calling; but on account of his mathematical attainments he was placed in charge of the calculation of the ship's accounts. His mathematical attainments brought him to a stand. Regarding the check as a call for greater exertions, he betook himself to a course of mathematical reading, and so interested did he become in this new study that the 20th year of his age was almost wholly devoted to it. There was no longer the same charm in commercial pursuits, or in the hope of a voyage. And now appeared a trait that marked his character through life—turning theory or knowledge to positive and practical uses. With a rude wooden sextant made by a carpenter, and a common clock, he began to make time-observations; and having observed the occultation of a star by the moon, he got therefrom, to his great joy, an approximate latitude of Bremen. He then wrote a paper on the subject that form a point of departure for the student, repay his toil, and animate him to renewed exertions.

From this time his progress in astronomical studies was surprisingly rapid. While still a clerk in a counting-house, he had formed designs of original inquiry, such as are exalted above the courts of science, and he devoted himself to them, and pursued them after the close of business. The modern-day equivalent of Besselius's rough observations of the comet of 1607 had been found by Baron Zach, while searching the collection of Harriot's papers in the possession of the Earl of Egremont, and these being the first official observations of that comet since known as Halley's—One of the most important discoveries in the field of astronomy—It was at the age of 21, that Besselius was appointed as an assistant to Schröter at Lilienthal in 1806. He was now an astronomer to all intents and purposes; and well did he justify the anticipations of his friends. Not many years elapsed before his name stood among the foremost of modern astronomers.

One of his first tasks at Lilienthal was a series of observations on the sixth, or Hungarian, satellite of Saturn, with a view to determine the mass of the planet and ring, on which he wrote an able and elaborate paper (published in the 'Königssberger Archiv für Naturwissenschaften'), discussing all the phenomena of attraction and the disturbing causes. It formed a subject for examination in after years, when more perfect instruments were available. He observed also the comet of 1807, by which, on the publication of the elements with an examination of the perturbations, in 1810, he gained the Lalande prize of the Academy of Sciences at Paris.

Bessel was one of the few men who thought even in perfect observations without getting from them some direct practical result. He says of himself, in the preface to his 'Untersuchungen,' "that he at no time felt any special predilection for one rather than another particular branch of astronomical observation—of that very difference; but they were all alike work of the same kind—of one working always to an immediate and definite object." He held, that an observer who "failed to deduce actual results from observations, with a distinct view to the improvement of knowledge," neglected an essential condition of success and usefulness; and that a whole life exemplified his conviction.
The king of Prussia having resolved to establish an observatory at Königsberg, Bessel was appointed director in 1810, and devoted himself with unfaltering industry to the building and the mounting of the instruments, fulfilling at the same time the associated duties of professor of astronomy and mathematics in the university. The establishment, which was finished in 1813, remains no less a monument of his skill and earnestness than a refuge from the world's distractions and the sorrows of war. Observations were published in the same year, and have been continued ever since with inconceivable benefit to practical astronomers.

Bessel married on a congenial home, Bessel married. His wife was daughter of Professor Hagen; he had by her one son and two daughters. And now, what he had done for the comet observations of 1807, he—also at Olbers' suggestion—undertook for Bradley's Greenwich observations, which, first published in 1776 but little known by the astronomers of the day. He had begun the task of digestion and reduction in 1807, and applying himself to it as his numerous avocations admitted, brought it to a close in 1818. The results of this long-continued labour have been for many years before the world in a folio volume, entitled 'Fundamenta Astronomica.' This work, published when the author was in his thirty-fourth year, is of such a nature that even grave philosophers can scarcely speak of it in sober terms; and yet, consistent with English modesty, during the twelve years' observations of Bradley. The book indeed cannot be over-praised. In the words of a scientific report—"Besides elaborate determinations of all the principal elements of the reduction, the errors of the instruments, the heat, the diurnal motion, parallax, observation, processing proper motion, it contains a catalogue of the mean places of 3222 fixed stars, observed between 1750 and 1769, with the best instruments in existence at that time, and reduced to the epoch of 1765, with a precision and accuracy of which there was no previous example. It now furnishes the best existing means of determining all those data which can only be deduced from a comparison of observations made at considerably distant intervals of time, and may be considered as the foundation of all the principal improvements which have been made in astronomy since the date of its publication." Schumacher's noteworthy remark, "One may almost assert that one exact and adequate calculator is capable of doing better service to astronomical science than two new observatories," in this case found its verification.

Bessel's reputation was established. In 1822 he was elected a foreign member of the Astronomical Society of London, and three years later of the Royal Society; and the scientific societies on the Continent hastened to enrol him among their associates. The king of Denmark conferred on him the order of the Dannebrog; and from his own sovereign, who was a steady friend, he received the order of civil merit and of the Red Eagle. He was appointed sea-captain and privy councillor; and the Berlin Academy awarded him his prize for his paper on the precession of the equinoxes.

Bessel's labours have been so numerous that anything more than a bare enumeration of them is scarcely possible. He improved the method of finding longitudes. He determined the length of the seconds' pendulum at his own observatory, and so perfectly, as to establish an epoch in the history of pendulum experiments. He showed that in all former observations an essential cause of error had been overlooked, namely, the mass of air dragged by the pendulum in its oscillations; and that the amount of consequent disturbance would have to be calculated for every pendulum. He investigated the causes of the irregularities of astronomical instruments, leaving nothing unaccounted for, till he surpassed all his contemporaries in his knowledge of the theory of instruments. He was employed to determine the Prussian standard of length; and in connecting the geodetical surveys of Russia with those of Prussia, and of the west and south of Europe; and displayed in these, as in his other labours, rare ingenuity in devising new methods and avoiding causes of error.

At the same time he measured an arc of the meridian of his observatory. Then, was his habit, taking the whole subject into view, he investigated the surveying of the British government in India and elsewhere, and of the French from the Belgian frontier to the Mediterranean, shrinking from no task that might aid in the accomplishment of his object. An error made in the French observations had been calculated and allowed for by four independent geometries; but Bessel, not satisfied with this, actually recalculated the whole of the work by his own method, producing a result agreeing with the mean of the four determinations alluded to, within an error of the order of the magnitude of the perpendicular.

At this time, he had completed a series of observations on the star 61 Cygni, to determine if possible the annual parallax of a fixed star—a task which had been the propitium of science. Thanks to his marvellous skill and delicacy of perception, he obtained results so perfect that the meteorologists, who is almost inconceivably small, only 31-100ths of a second, astronomers agree in considering them as demonstrated. By observations of other fixed stars, Sirius and Procyon, he himself authorised the announcement of minuscule irregularities in their motions as a positive astronomical fact. And he threw out a speculation as to the cause: namely, that the stars in question are double stars, of which one is not luminous; hence we see the disturbances, but not the double star.

A more trustworthy guide than Bessel could not be followed: to his example the present excellence of astronomical science in Germany is due. He was a copious writer; the more remarkable, as his writings exhibit proofs of as much profound research, as of an inordinate variety of attainments. His 'Table Regiomontana,' which may be regarded as a supplement to the 'Fundamenta,' &c., appeared in 1830. Nearly two hundred papers, neither short nor unimportant, in the 'Observations' and 'Astronomische Untersuchungen,' and, as is said, left a third in preparation. He was a scholar, a poet, and a scholar; and was esteemed and honoured in a way accordant with his desert. There is reason to believe that on his return he intended to investigate the problem which, in the hands of Adams and Le Verrier, led to the discovery of Neptune. The preliminary reductions were made; but grief was felt, and a young man of great promise, who died in 1841, and the approaches of disease of a very painful nature upon the astronomer himself, stayed his inquiring spirit. His sufferings became more acute; and he died in his house in Berlin. He died on the 7th March, 1846, at the age of sixty-two.

BETEL-NUT-PALM. [Anac.] BETELM, SIR WILLIAM, was born in 1779 at Stradbrooke in Suffolk. His father was the Rev. William Betham, author of 'Genealogical Tables of the Sovereigns of the World,' folio,1795, and of a 'Baronetage,' in 5 vols. 4to published in 1801-1805. Although young Betham appears to have inherited his father's tastes, he had to carve out his own career. He was appointed in 1803 to the post of Secretary to a printer in London. His first literary employment was in the revision of the 3rd and 4th volumes of Gough's edition of Camden's 'Britannia.'

In 1805 he went to Dublin as clerk to Sir Charles Forte and the Bar. A few years later he became the deputy to Sir Charles; and he succeeded him as Ulster King of Arms in 1820. Mr. Betham was appointed Genealogist of the order of St. Patrick in July 1815, on which occasion he was knighted. He also received the appointment of Deputy Keeper of Records at Dublin; an office in itself of little emolument, but which placed under his control a large number of records, of which he availed himself to form an immense collection of historical and genealogical references extending to several hundred volumes, which has since served as an individual store-house in family, historical, and legal inquiries. Sir William also formed an index to the names of all persons mentioned in the wills deposited at the Prerogative Office, Dublin; a task which occupied a considerable portion of his time from 1807 to 1815, and extended to 40 large folio volumes. Sir William was like wise a diligent collector of old manuscripts connected with Irish history and antiquities; his collection was purchased by the Irish Academy in 1821.

Sir William Betham was elected in 1825 a member of the Irish Academy, and soon after became its foreign secretary which office he held till 1840, when he resigned it in consequence of the council refusing admission in the Tract Society. He was a zealous and cledulous antiquary, and some of his archeological and philological speculations were of a very singular and wholly untenable character. But a. most strenuous and indefatigable in his investigation of primate Irish, or rather Celtic, antiquities; and he fancied that he had discovered traces of the connected
BET

BIC

is of the Celtic races with several of the most remarkable
unities of antiquity. His first separate antiquarian publica-
tion, 'Irish Antiquarian Researches, or Illustrations of Irish
History,' 1826-7, contains many of his peculiar views; but
the most important work of the period was 'Topographical
works,' the titles of which sufficiently indicate the
character of his notions: the first of these was entitled
'The Gael and the Celt.' In the 'Transactions of the
Irish Academy,' which have for the last years been
published weekly by the Council, he contributed a
series of communications in the 'Transactions of the
Irish Academy.' He was elected a Fellow of the Society of
Antiquaries, London, in 1855, but only two or three papers by him were printed in the
'Archaeologia.'

In his own line of research Sir William was a
most trustworthy guide. Besides several genealogical
memorials, and a valuable work on 'Parliamentary and
Feudal

Bishops,' Sir William published in 1834 an able and learning
book on 'The Origin and History of the Constitution of
Ireland,' of the early Parliaments of Ireland.' (In his

Geography)

BROFAL [BOPAL]

BICKERSTAFF, ISAAC, was born in Ireland probably
about 1755. He was one of the pages of Lord Chesterfield,
who became Lord-Lieutenant of Ireland in 1746. A
fterwards he became an officer in the marines, in which service
he continued until forced to quit under circumstances of
a lightness which is known. He published a number of light comedies and musical pieces, under
Garriick's management, of which some yet remain in
the vaults of the stage. The principal are—Love in
York, 1763; the 'Maid of the Mill,' 1766; 'Love in the
City,' 1767; the 'Hypocrite,' 1768; 'Alistair and Clarissa,' 1768;
the 'Fellow,' 1768; 'The Captive,' 1769; 'He Would if
He Could,' 1769. His last piece, 'The Sultan,' was produced
in 1773. The music to many of these pieces was composed
by Charles Dibdin. The time and manner of Bickerstaff's
death are uncertain; all that is known is that he withdrew
from the continent, and died in obscurity. (Biographia
Draco.)

BICKERSTAFF, THOMAS EDWARD, was born March 19,
1766, at Kirkby Lonsdale, Westmoreland. He was the fourth
son of Mr. Henry Bickerstaff, a surgeon of that town, and
the younger brother of the late Lord Langdale, Master of the
Rolls. He received his elementary education at the grammar
school of Kirkby Lonsdale, but was removed thence to receiving a
schooling in the post-office, London, at the age of fourteen.
Here he remained for six years, when he was received into
the office of Mr. Bleasdale, a London attorney, as an articled
clerk. In 1785 he was admitted into partnership with Mr. Bignold, a fellow clerk, whose
father he married, and commenced business as a solicitor in
Norwich in 1812.

The business soon developed a flourishing one, and Mr.
Bickerstaff was extensively employed very favourably. But he
had become deeply impressed with the importance of religious
truths, and he soon took a prominent part in the various
religious movements for which Norwich was becoming cele-
lated. The Norwich Church Missionary Society was founded
by him, and he was active in promoting the operations of the
Bible Society, and several other religious societies in that
city. He also wrote and published, in 1814, 'A Help to
the Study of the Scriptures,' which in its enlarged form has
had a considerable sale. He was a gentleman of strong
feelings, aided perhaps by an acquaintance he had formed
with Mr. Pratt, Mr. Budd, and some other leading clergymen
of the 'evangelical' section of the church, led him to desire
the ministry. The officials of the society, the members of which
gentlemen strongly encouraged. Accordingly, Mr. Bickerstaff
was, December 10, 1815, ordained a deacon of the Church of
England; the Bishop of Norwich having been induced to
dispensary in this case with the usual university
training, in conformity with the views of its being necessary
that those who entered the church should possess a
knowledge of the state in Africa, and to act afterwards as
their secretary. A fortnight
later the Bishop of Gloucester admitted him to full orders,
and he almost immediately departed with his wife to Africa.
He returned in the following autumn, having satisfactorily
accomplished the purposes of his visit.

He continued in the full discharge of the duties of his
secretaryship for the next fifteen years, organizing new and
visiting old branch associations, directing the studies of the
missionaries, continually advocating the interests of the
church in the pulpit and on the platform, as well as with
his own congregation. He also travelled through all parts of the
kingdom, acquiring a constantly increasing amount of influence and popularity in what is
commonly designated the religious world. At the end of 1830 he resigned his office, and also his ministerial charge at
Whiter Chapel, Leeds, and again took up his residence at
Watton in Hertfordshire. At Watton, Mr. Bickerstaff spent
the remaining twenty years of his life. But his labours were
not by no means bounded by his parish. He was during the
whole of that period, a constant reader of sermons and
speeches, not only of the missionary, but of almost every other religious society connected
with the church, or in which, as in the Bible Society, and the
Evangelical Alliance (of which he was one of the founders),
churchmen and dissenters associate. And he also spent
some time during his residence at Watton a constant succession of
religious publications, which were for the most part
read in the circles to which they were chiefly addressed with
the greatest avidity. Indeed it may be said that during most
of these last years of his life Mr. Bickerstaff was
one of the most influential and generally popular clergymen
of that section of his brethren among whom he was
classed.

During this period he took a very decided part in all those
measures which he regarded as having a direct bearing on
the religious condition of the country. He was especially earnest in opposing the Maynooth grant, and in calling for its
withdrawal; and he was equally zealous in denouncing the
Spanish ambassador, and the pretended atrocities of the
English people in South America; and yet his opposition was free from all personal
bitterness, and his influence was directed to softening the
aspersions of religious strifes. In his later years he
manifested a growing interest in the study of prophecy. The
unfulfilled prophecies were made the frequent subject of his
discourses, and he published several pamphlets and tracts
and three or four elaborate treatises in elucidation of the
prophetic writings.

His principal works besides the 'Scripture Help' already
noticed, and a large number of sermons, tracts, &c., were
- 'The Christian Student,' 'A Treatise on the Lord's Supper,'
- 'A Treatise on Prayer,' 'Family Expositions of the Epistles
of St. John and St. Peter,' 'A Treatise on Baptism,' The
Signs of the Times,' 'The Passion of our Lord Jesus
Christ,' 'The Restoration of the Jews,' 'A Practical Guide
to the Prophecies,' &c. His collected works have been
published in 16 vols. 8vo. Among his literary labours ought
to be also mentioned a large work which he compiled, and
the 'Christian Family Library,' which he edited, and which
extended to fifty volumes.

Mr. Bickerstaff was in 1843 attacked by paralysis, the
result of too prolonged mental exertion. He recovered from
this, and resumed his labours. He then proceeded to a meeting of the Evangelical Alliance, thrown
from his chaise under a heavily laden cart, the wheels of
which passed over him; but though dreadfully injured he
was after a time restored to health and activity, and survived

Music. He was also Reid professor of music at Edinburgh; and in 1848 was elected professor of music at Oxford University. He died April 30, 1856, aged 78. Sir Henry had heavy domestic trials, and he was not present at his more successful days, so that his later years were clouded by much anxiety and suffering.

Bishop was one of the first English composers of modern times. Had there been less he would have written better; but as it is, though few if any of his compositions are command to retain a permanent place on the stage, and his elaborate imitative philharmonic cantatas have long been forgotten, much of his chamber and concert music.—married as it so to the centre of the science of harmony, and corresponded with many of the most eminent men of science. He died on February 18, 1856, at Venice.

BILLY OF LADING. The indemnity of a Bill of Lading now not only transfers the property in the goods therein mentioned, but also all the rights and liabilities inter se of the original parties thereto. It is also conclusive evidence as against the master of the ship therein mentioned (18 & 19 Vict. c. 111).

BILLY OF SALE. A Bill of Sale of personal chattels must be registered within twenty-one days after the making thereof in the judgment office of the Queen's Bench, otherwise it will, as against assignees in bankruptcy or insolvent, or creditors, be null and void (17 & 18 Vict. c. 36.)

BILLY OF SALE, a genus of plant of the order Dicotyledonae, after Billberg, a Swedish botanist. Several species are cultivated in our gardens. They are all natives of South America. One of the species, B. tinctoria, yields a colouring matter, which is used for dyeing in Mexico.

BILLY'S MACKINZIE. [MAN.] BILIMAN, the first order of the class Mammalia, which includes the single genus and species Homo sapiens—Man.

BILLYMON. [BARREL.] BISHOP, SIR HENRY ROWLEY, was born in London in 1780. He received his musical education under Signor Bianchi, who was then settled in London as composer at the Opera House. In 1806 Mr. Bishop obtained the appointment of composer of ballet music at the opera, a post he held for twenty years. In 1811 he added music director of the theatre to his title of composer. During this period he is said to have produced upwards of seventy operas, ballets, and musical entertainments. Of these many are forgot; but others are still repeated, and, on account of their flowing melodies and animated style, are now esteemed among the choicest works of the kind. Those which best illustrate his style are 'Guy Mannering,' the 'Slave,' the 'Miller and his Men,' 'Maid Marian,' 'Native Land,' the 'Virgin of the Sun,' the 'Knight of Snowdon,' the 'Englishman in India,' &c., in all of which there is true musical power. He also composed and adapted Mozart's 'Barber of Seville,' 'Marriage of Figaro,' &c., but the incessant calls upon him begot a hasty careless manner, and he frequently, in the later years of his connection with the opera, appears himself as conductor of the scores of foreign composers; and his fame in consequence gradually declined. At length, aroused by the production of Weber's 'Oberon' at Covent Garden Theatre, in 1826, he composed 'Aladdin' in direct rivalry to that famous work, and brought it out at the same time. During residence there, instead of trusting to his own genius, 'Aladdin' was a direct attempt in the German style, and it proved an entire failure. Mortified at his loss of popularity, he never again composed for the opera, and the few of his theatrical pieces, he composed about 1819-20. He arranged also several volumes of the 'National Melodies;' and he composed and arranged as the 'Melodies' subsequent to Stevenson's accession from that position.

Sir Henry Bishop was knighted in acknowledgment of his musical eminence by the Queen soon after her accession to the throne. He was one of the first directors of the Philharmonic Society, and conductor of the Concerts of Ancient
for several years. The position of this fortress as given in the 'Royal Geographical Journal,' vol. x., is 38° 23' 54'" N. lat. 45° 4' 49" E. long.; on the map in Dr. Leyard's 'Nineveh and Babylon,' the town is placed 3° 9' farther east.

In point of trade Bitlis is an important place. The exports are chiefly galls, honey, wax, wool, and gum tragacanth from the mountains of Kurdistan and Armenia, carpets and cotton stuffs woven in the town and neighbourhood, and dyed here in numerous colours. In the 18th century these Mollauncas or Molluscans were famous for the brilliancy; they are made from mountain herbs, and from indigo, yellow berries, and other materials which are imported. The raw cotton used in their manufactures is brought either from the Celebs or the Cossacks, and cotton goods (cotton also supply saddler), and some of it is imported from Khoj, in Permia. It is spun by hand; and several hundred thousand short heavy calico pieces are manufactured throughout the country, of which Bitlis is the centre, and sent here to be dyed. The favourite colours among the Kurds are a dull red deep, and a bright yellow mingles or striped with black. The carpets are of a rich soft texture, with patterns displaying considerable elegance and taste; they are much esteemed in Turkey. Manchester goods, including unblesched calicoes, shawls, and prints; gay-coloured silks and satines, some woollen clothes and coarse cutely are comprised in the list of British goods sold in the bazaars. The manufactures of Damascus, Aleppo, and Diyar-Bekr are more extensively used. Bitlis is said to be an ancient place. Until lately it was governed by Kuridh Begs, who were but little under the control of the Porte. Sherif Beg, the last of these lawless chiefs, was exiled to Constantino in 1849, after the so called | marks or apparent seals, and the names of the persons are added. Since then, the town is now governed under the Pasha of Musha.

BIVALVE. A name applied to those forms of Shell-Fish which have two shells, or valves, in contradistinction to those which have one shell, and which are called Univalve. [MOLLUSCA.] Before the structure of the Cephalopod Animals was as well known as it is at the present day, the Barnacles and Sea Acorns, which have several external valves, or shells, were referred to the Mollusca, under the name of Multivalves.

BLACK JACK, the same name given by miners to the Sulphur of Vesuvius.

BLADDER, DISEASES OF. [See URETHRA, &c.]

BLAINVILLE, HENRY MARIE DUCROTAY DE, a distinguished zoologist, was born at Arques near Dieppe, Sept. 12, 1779, of a noble and ancient family. He went first to the military school at Beaucourt-en-Auge, being destined for the army; but left it suddenly in 1793, and, as is said, shipped on board a channel cruiser, and took part in some engagements with English vessels. Afterwards he enrolled himself at the École normale, and in 1802, received the conscription of 1798, but obtained exemption through a partial stiffness of the right arm caused by an accident. He remained at Paris without any definite plan of life, occupying himself in a desultory manner by attending lectures on the natural sciences at the Collège de France, and at the École normale, where he became very expert. He had reached the age of twenty-seven, when, having heard one of Cuvier's eloquent lectures at the Collège de France, he resolved on devoting himself to the science of comparative anatomy, and at once entered as student in the School of Medicine. Here he took his degree of Doctor of Medicine in 1808, after three years of study; and chose as the subject of his inaugural dissertation, the influence of the eight pair of nerves in respiration, as demonstrated in the animal and vegetable王国. The science of anatomy now became De Blainville's sole pursuit. His remarkable skill as a draughtsman led to his merits being recognised by Cuvier, who employed him as practical anatomist and artist at a salary of 2000 francs a year, and the great Cuvier was so impressed by his assistant's ability, that he intrusted to him the delivery of a part of his course of lectures on zoology at the college. It was De Blainville's ambition to become professor, and in 1812 he composed a treatise on animal physiology, on the analogy of the physiology at the Faculty of Sciences. Having won the honourable post, he defended his well-known thesis on 'The Natural Affinities of the Ornithorhynchus Paradoxus.'

A flattering political position, obtained through his influential connexion with the restorers of the Bonapartes, was offered to De Blainville: but he resisted the allurements of public life for his favourite science. He came to England in 1816, and during a short stay, made diligent use of his opportunities for adding to his zoological knowledge, and carried away drawings of the rare Mollusca in the British Museum, and of anatomical specimens in the museum of the Royal College of Surgeons. Some of his papers, published in the ' Bulletin de la Société Philomathique,' bear a testimony to the good use he made of his sojourn in this country.

In 1825 De Blainville was elected a member of the Academy of Sciences at Paris. On the retirement of Lamarck in 1830, he was appointed to the chair of the natural history of the annelids, and the molluscs. After the death of Madame Cuvier's Cuvier's death in 1832, he was appointed to succeed great anatomist as professor of comparative anatomy in the same establishment. Thus in twenty-eight years after his return from a life of scientific study, he found himself as the result of his rapid advance, in an eminent position, and acknowledged head of one of the most important branches of science. In the same year he was elected a foreign member of the Royal Society, and subsequently of the Geological Society of London. He was also a member of other scientific societies on the continent.

De Blainville availed himself of his new position to commence what has since been recognised as his great work: 'Ostéographie, ou Description Iconographique comparée du Squelette et du Système Dentaire des Cinquante d'Animaux Vertébrés récents et fossiles,' &c. Twenty-three parts of this magnificent work had been published, and the author had corrected the twenty-fourth part ('Camelus'), when on the arrival at Rouen of a railway train in which he had taken a sleeping place, he was confronted by a later edition of this work. This was the 1st of May 1850. On the previous day he had delivered his usual lecture: "exhibiting," says M. Prévost, "a freshness of ideas, and facility of expression, which bore no marks or approximation to all that he had done before, and which it seemed that nothing had been experienced during the year past, but, with a force of character peculiar to him, he had sought to conceal them from all, even from himself." All attempts at resuscitation proved unavailing, and he died a few minutes after his return from the carriage ride.

De Blainville's writings are to be found in the 'Dictionnaire de Histoire Naturelle,' the 'Bulletin' above-mentioned, the 'Annales' and 'Mémorials du Muséum,' the 'Annales des Sciences de l'École normale,' 'Revue Zoologique,' and other scientific periodicals. Of separate works, he may be remembered his 'Dissertation sur la place que la Famille des Ornithorhynques et des Echidnes doit occuper dans la Série Naturelle,' 4to, Paris, 1812; 'Sur les Ichthyolites,' &c., 8vo, Paris, 1818; 'Mammifères et Poissons de la France Française,' 8vo, Paris, 1820-30; 'Principes d'Anatomie Comparées,' 2 vols. 8vo, Paris, 1822-23; 'Mémoire sur les Bélénus,' 4to, Paris, 1827; 'Cours de Physiologie générale et comparée,' 3 vols. 8vo, Paris, 1833; ' Manuel d'Actinologie et de Zoologic,' 8vo, 1838.

The fact that De Blainville's writings number nearly 900 in the whole, will best give a notion of his activity and devotion to science; they comprise researches in all branches of zoology and malacology, and elaborate treatises which alone would employ the labour of a life. The former includes extant as well as living animals, and is of rare importance to palaeontologists.

De Blainville had a public funeral in Père-la-Chaise. Prévost, Chevreul, and Milne-Edwards each pronounced a discourse over his grave. A passage from the former presents a concise view of what he accomplished. "It was the great object of his life," says M. Prévost, "to establish in all his works, especially in his 'Osteologie,' the doctrine that the whole vegetable and animal kingdom are but the links of one great chain, ascending from the most simple of organisms to that which occupies the highest place; in other words, from the sponge to man. But while he endeavoured to refer all groups and every variety of animal form to one and the same plan, he never embraced the plausible hypothesis that each higher grade had been improved in the course of ages out of a lower one by transmutation; on the contrary, he saw in the whole animal creation one single and simple structure, in which all the changes being neither due to chance nor to the influence of external circumstances, but being all the result of one and the same original conception."

BLAKE, a genus of plants belonging to the natural order Melastomataceae, named by Dr. Patrick Browne in honour of Martin Blake. The species are trees or shrubs, with

K 2
large showy red flowers. The calyx is girded with from four to six broad scales; the corolla with six petals; the fruit a gourd-like ovary, with the 'Fawn' a, ovary-shaped from three to five nerves. B. quinquenervis, Aublet, B. tripinnervis, Linnaeus, is a native of Brazil, Guyana, and Trinidad. It produces a large yellow berry, which is eaten in the countries where it grows. B. parrasii is a native of Guatemala. B. divaricatum is a spreading shrubby plant, rooting itself in other trees. It yields a colouring matter, employed for dying red.

BLANCHARD, LAMAN, was born at Great Yarmouth, Norfolk, on April 15, 1827, His father having removed to London, Laman was educated at St. Olave's school, Southwark. He commenced the business of life as reader in a printing office. From boyhood he had exhibited a great fondness for poetry, and considerable aptitude in verse making; and his first ventures in this direction was a little volume entitled 'The Lyric Offering,' published in 1826. Before this, however, in 1827, he had received the appointment of secretary to the Zoological Society. This office he held till 1837, when he resigned it to become acting editor of the 'New Monthly Magazine.' From this time till his death his talents were wholly devoted to writing for the periodical press, to which he was one of the most varied and prolific contributors. His contributions consisted of poems, essays, the occasional letter, and pointed personal criticism. The fact was most required for the magazine or journal with which he was at the time connected; and all of them displayed a lively and genial fancy and a ready wit. Mr. Blanchard edited the 'True Sun' newspaper during the whole of the period of Constitution in 1832. He was a frequent contributor to 'The Court Journal,' and the 'Courier.' For some time previous to his death he had assisted in conducting the 'Examiner.' His death occurred under very painful circumstances. It is said that he was much distressed about a year before his decease, and his illness ended in insanity. He rallied for awhile, but relapsed and died. Under the prolonged anxiety attending her long illness and its fatal termination, his own health and spirits gave way. In 1845 his daughter, Mrs. Blanchard, died. One of these, put an end to his life, February 15, 1845. His death excited much sympathy, especially among his literary brethren, by whom he was greatly esteemed. His 'Essays and Sketches' have been collected and published, with a Memoir by Sir E. Belcher Lytton.

BLESSINGTON. [WITSCLOW.]

BLESSINGTON, MARGUERITE, COUNTESS OF, was born at Knockbrit, near Collen, Tipperary county, Ireland, on March 19, 1786. She was the youngest daughter of Mr. Edmund Power, who was of respectable family, but broken fortune and reckless habits. She was married in her twentieth year to a Captain Farmer, but the marriage was a very unhappy one, and Mrs. Farmer after a time separated from her husband. He was killed by falling from one of these, put an end to his life, February 15, 1845. His death excited much sympathy, especially among his literary brethren, by whom he was greatly esteemed. His 'Essays and Sketches' have been collected and published, with a Memoir by Sir E. Belcher Lytton.

years he held his important post, was much canvassed. But besides his watchful supervision of the general interests of the Church, Bishop Blomfield was a careful overseer of the clergy of his diocese, and prompt to support any proposition which appeared likely to improve the condition of the labouring classes in the metropolis. Nor in the briefest notice of Bishop Blomfield ought the amazing success of his efforts for increasing the number of churches to pass unmentioned. While Bishop of Chester he zealously set on foot the formation of new churches in the city properly supplied; but it is in his London diocese that success most splendidly crowned his labours. During the time that he held the see there were built in his diocese a number of churches remarkable rather than in the predominance of any other bishop since the Reformation; yet one of his most recent public acts was to make an earnest appeal, seconded by a large subscription, to the affluent and liberal to endeavour by a vigorous effort to raise funds sufficient, if possible, to construct as many additional churches as the Census Report of the Registrar-General shows are still needed to meet the wants of the vast and rapidly increasing population of the metropolis.

The theological writings of Bishop Blomfield consist of "Lectures on the Apostles," and of numerous Sermons and Charges. Bishop Blomfield in 1856 resigned his bishopric, and was succeeded by Dr. Tait. He died August 5, 1857, at Fullham, near London.

BLOODSTONE, also called Heliotrope, is a deep green stone—a variegated variety of quartz. It has obtained its name from being spotted with red so as to resemble drops of blood. In addition to silica, it contains oxides of iron and clay, which are responsible for its colour. Bloodstone is used as a gemstone and in jewelry.

BLOOD-VESSELS. These are vessels through which the tissues of the body obtain the material of their nourishment, conveyed from one part of the body to another by means of branched tubes which are named Blood-Vessels. It is carried along these vessels by the impulse given by the action of the Heart. [Veins.] The vessels which carry the blood from the hearts are called Arteries. [Artery.] Those which return the blood to the heart are named Veins. [Vein.] Whilst a very generally diffused net-work of Blood-Vessels exist, connecting the arteries and veins, which are called Capillaries.

The Blood-Vessels, whatever may be their ultimate destination, seem to originate in the same manner. Observations on this subject have been made by Schwann and Kölliker in Germany, and by Professor Paget in this country. The observations of Schwann and Kölliker have been confirmed by the experiments made in this country by Mr. J. M. Pointing. The method employed by the latter author is the same as that of Schwann and Kölliker. The time is now however come when the student will be enabled to form an impression of the internal structure of the blood-vessels by the use of the dissecting microscope. The blood-vessels of different parts of the body are of different sizes and shapes, and are found in different relations, according to the nature of the parts to which they are supplied. The blood-vessels are supplied with nerves, and these nerves are connected with the sensory nerves of the body. The blood-vessels are supplied with blood, and this blood is conveyed from the heart by the arteries, and returned to the heart by the veins. The blood-vessels are also supplied with blood from the veins, and this blood is conveyed from the heart by the arteries, and returned to the heart by the veins. The blood-vessels are also supplied with blood from the veins, and this blood is conveyed from the heart by the arteries, and returned to the heart by the veins.

BOERHAAVIA, a genus of plants belonging to the natural order Urticaeae. The species were formerly comprehended under the genus Urtica. One of the species, B. nivea, formerly Urtica nivea, is the Rheuma of Asam, and yields fibres as abundant and of equal strength and quality. They appear from the investigations of Dr. Falconer, that the plant which yields the celebrated grass-cloth of China is identical with the Asam plant. Several specimens of these fibres manufactured into light articles of dress were exhibited in the Indian collection at the Great Exhibition of 1851. The B. nivea is a herbaceous plant, with broad ovate leaves, which are downy and white beneath, hence its specific name. It bears no stings.

BOGORIA, a genus of plants named after the celebrated Borebava, belonging to the natural order Nyctaginaceae. The species of Boerhavia have generally emetic and purgative properties, and have been employed medicinally both by the natives of Peru and the East Indies, where the species known by B. tuba and by B. tuba americana. These plants are cultivated in Peru, and that it is employed as a culinary vegetable. The root of B. decumbens is called Hog-Meat in Jamaica, and on account of its emetic properties it is sometimes called Ipsecoacanha in Guiana. Sir Robert Schomburgk states, that this root is employed in dysentery. B. decumbens and B. hispanica are also said to possess medicinal properties. (Lindley, Vegetable Kingdom.)

BOG-IRON-ORE, a loose earthy ore of iron, consisting of Peridotite of Iron and water. It is of a brownish-black colour, and occurs in low boggy grounds.

BOGMARUS, a genus of Fishes, to which the Vasa, or Deel-Fish, is referred by Schneider under the specific title of B. Islandicus. [TASCYLYRUS, S. E.]

BOLDO, a genus of plants belonging to the natural order Monimiaceae. B. fragrans is the Boldo of Chili. It produces an aromatic succulent fruit, which is eaten by the natives. The wood is very fragrant, and makes a charcoal which is preferred by the smiths of Chili to that from any other wood. The leaves are also very fragrant. The bark is employed in tanning.

BOISSONADNE, JEAN-FRANCOIS, was born in Paris, August 12, 1774. Towards the end of the year 1792 Boissonade entered into the public service under the ministry of General Dumouriez; he was appointed aules-enregistreuse in 1795, but was restored in 1801 by Lucien Bonaparte, who was then minister of the interior, and who made him secretary-general of the prefecture of the Haute-Marne. He was a member of the council of the minister of agriculture, and was from 1808 to 1810 under the name of Duport, then retired; and thenceforward devoted himself to literature, which had indeed previously occupied nearly all his leisure hours. He had from the year 1802 contributed numerous articles to the periodicals of the day. In 1808 he was appointed professor of the Greek language and literature in the Académie de Paris, but assumed only the title of assistant-professor, resigning the title of professor to Larcher, who retained it till his death in 1812. Boissonade then succeeded him, and he continued his professorship until 1830. His works include Inscriptions et Belles-Lettres. On the death of J. B. de Gaul in 1826, Boissonade was appointed professor of Greek in the Collège de France. Other situations of honour and emolument were afterwards offered to him, but he declined to accept any of them.

M. Boissonade occupied a considerable portion of his time in the critical examination of Greek writers previously unedited, and published a very large number of works and fragments of works by Philostratus, Proclus, Tiberius the Locrian, Holkentius, Herodesaurus, Dunapits, Aristaeus, and several others.

In the period from 1823 to 1826 Boissonade published in 24 vols. 32mo, a "Syllogon Posteriorum Graecorum," and in connexion with this work he published in 1839, in a monastery at Athens, of a manuscript which contained a large number of the lost Fables of Babrius. Boissonade published "Babri Fabule Iambiques," 8vo, Paris, 1844. [BABIUS.] Boissonade contributed to the edition of "Athenaeus" by
Schweighaeuser, to the 'Euripides' of Matthieu, and to the edition of Stephen's 'Thesaurus Græce Lingue,' which was published in London in 1694. He wrote several articles for Valpy's 'Classical Journal,' and he gave his assistance to the Paris edition of Stephen's 'Thesaurus,' printed by Didot. M. Boissonade was an indefatigable labourer not only in Greek but also in modern languages. He published several editions of the unedited letters of Voltaire, of the works of Parny, and having furnished a large number of the lives in the 'Biographie Universelle.' He died Sept. 12, 1857.

C. K. N. (Hered.)

BOLINGBROKE. [LONGMIRE].

BOLITOPHAGUS (Fabricius), Eleodora of Latreille, Leach, and Millard, and Opunturum of some other authors, a genus of Coleoptera Insecta, of the section Heterocera and family Carabidae. The principal species of the type, as follows:—Head short, partially hidden by the thorax, in the males sometimes armed with a horn or tubercle; antennae very short and thick, the three or four apical joints much broader than the rest; maxillary palpi rather large and distinct, the terminal joint truncated, its length equaling that of the two preceding joints; labial palpi small; thorax coarsely punctured or rugose, the lateral margins more or less toothed; elytra deeply striated; legs short and thick, the hind one long.

There are about six species of this genus known; they live in Bolati, and are of a small size, a short ovate form, and their prevailing colours are brown-black. In this country but one species has as yet been discovered, B. Aguacola or A. urticae, which has a brown-coloured body, about one-twelfth of an inch long. It is rather local, but where it does occur it is found in tolerable abundance.

BOLORENTITE. [CHEMISTRY. S. 2.]

BOLTANITE, a native anhydrous Silicate of Magnesia. It occurs massive with a granular structure, or in yellowish or bluish-gray grains. The cleavage is in one direction; the lustre vitreous; transparent to translucent. It is found disseminated through limestones in the United States of America, Massachusetts, and of ridefield and Reading, Connecticut.

BONA NOTABILIA. [EXTRACTS.] The doctrine of Bona Notabila has been abolished with the Courts whose jurisdiction depended on it, there being now but one Court of Probate for all England. [PROBATE, S. 3.]

BONAPARTE, CHARLES LUCIEN JULES LAUNCE, Prince of Canino, eldest son of Lucien Bonaparte, was born at Paris, May 24, 1803. He received a careful education, and always exhibited a much greater attachment to Rome than to his native Paris. As a naturalist the Prince of Canino acquired great distinction. In ornithology especially, he is generally regarded as one of the chief modern authorities; and he was elected a member of the Royal Academy of Sciences of Turin, of Turin, and of the Royal Institute of America. For some years the Prince resided in the United States, and it was by his writings on the Birds of America that he first made himself known to the scientific world. His chief publications are a continuation of Wilson's 'Ornithology of America,' in four folio volumes; and the 'Iconografa della Fauna Italiana,' a splendidly illustrated work in three volumes folio. But besides these he published numerous essays and memoirs on particulars of American ornithology, and on other branches of natural history in the scientific journals of the United States and Europe. The Prince was always the zealous friend and patron of the vocation of science, and for many years he was the chief promoter of the annual congresses of the scientific men of Italy. He died July 30, 1857, in Paris.

Prince Charles Bonaparte married at Brussels, June 9th, 1852, Zenaide-Charlotte, daughter of his uncle Joseph Bonaparte, by whom he had ten children, of whom three were alive.

BONAPARTE, LOUIS NAPOLEON, the fourth son of Charles Bonaparte, and father of Napoleon III., was born at Ajaccio in Corsica, September 21, 1778. At an early age he entered the French army, and accompanied his brother Napoleon to Egypt. He was distinguished himself at the passage of the bridge of Arcole, bravery of fire, and shielding the body of his brother and commander. When Napoleon became first consul, he was sent on a mission to St. Petersburgh; but on arriving at Berlin he learned the news of the death of the Emperor Paul. He returned to Paris after remaining at Berlin about a year, and became a general of brigades, a counsellor of state, and afterwards a general of division. In 1802 he married Horatia Anne de Beauharnais, the daughter of the Empress Josephine.

When Napoleon became Emperor, Louis Bonaparte was promoted to higher honours, and was made governor of Piedmont, and afterwards commanded the army of the north of France. In 1808, Napoleon sent him with 25,000 men into a kingdom, the states of Holland in June 1806 sent an embassy to Napoleon, requesting that Louis might be their king, which was granted, and he immediately assumed the title of Louis the First. He strongly exerted himself to improve the condition of his people, and distinguished himself on several occasions by his personal humanity. His love for his people occasioned him to refuse without hesitation the offer made him by his brother of the crown of Spain; but his refusal only made him more unpopular. He endeavoured to guard against any prejudice to their welfare, gave great dissatisfaction at Paris. His wife was a most attached adherent of Napoleon's, and her inability to control her husband, the death of her eldest son in 1807, and the state of her health, induced her to remove to Paris, where she died in 1809. She was afterwards sent by Napoleon in 1809 to induce Louis to comply with his wishes, but Louis refused. She then returned to Paris, where she resided as state in Queen of Holland, and in 1810, Louis Napoleon, with 300,000 men, agreed to his wife's proposal in favour of his son which abdication Napoleon rejected; and on July 9, 1810, Holland was united to the French Empire. Louis retired to Gratz in Styria, where he lived three years under the title of Count of St. Leu. Louis Napoleon became wholly separated from him, though not divorced.

In 1813, when the allied armies appeared about to fall upon France, Louis offered his services to the Emperor, by whom they were accepted, and he proceeded to Switzerland, but he was not employed by Napoleon, until the Dutch threw off the French yoke, Louis addressed a letter to the provisional government from Soleure, asserting his claims to the throne, but they were rejected, and he then commenced a suit at Paris for the recognition of his title, the residence of his two eldest sons, living in the service of their mother, who had obtained a grant of the domain of St. Leu, with the title of Duchess, through the interest of the Emperor Alexander. The return of Napoleon put a stop to the suit, and the Duchess of St. Leu did the honours of Napoleon's court, and used her interest in favour of the unfortunate of all parties. After the battle of Waterloo she went to reside in Switzerland with her sons. Louis retired to the Papal States, where others of his family had assembled, and devoted himself entirely to his service of his native country. He died at Clusel, near Nimes, in 1815. After the death of his father in 1824, and the return of his elder brother, Louis Napoleon wrote a History of Napoleon. He died at Lethem, June 15, 1846; and at his special desire, which after some delay was acceded to, his body was buried at St. Leu in France, with those of his father and his first son. September 29, 1847.

BONE-BEDS. Accumulations of the bones of extinct animals, more especially of fish and Saurian reptiles, are not uncommon in various strata, and have had this name given them by geologists. They generally occur at the termination of one formation and the commencement of another. These Bone-Beds are local, and are not in any case very extensive. The thickest and most widely-distributed is that of the Lias, which seems to mark the commencement of the New Red Sandstone epoch. The most remarkable Bone-Beds are the following:

Bone-Bed at the base of the Lower Greensand at its junction with the Wealden; at the base of the Inferior Oolite, at its junction with the Lias; at the base of the Lias, at its junction with the Red-Marl; at the base of the Red-Marl, at its junction with the Old Red-Sandstone; at the base of the Old Red-Sandstone, at its junction with the Ludlow Rock of the Silurian System.

BONGARDI, a genus of plants belonging to the natural order Berberidaceae, or Berberidaceae. [BERBERIDACEAE.]

BONHILL, a town in the parish of Bonhill and district of Lennox or Lennoo, Dumfartshire, Scotland. The parish is divided in its length into almost equal parts by the south
end of Loch Lomond, and the river formed by it, the Leven, from which the district derives its name, and which falls into the Clyde at Dumbarton. The population of the town of Bonhill in 1851 was 2527.

The town is situated on both banks of the Leven, about five miles above Dumbarton. A mile nearer this town, and at the right bank of the stream, is the thriving village of Alexandria, with a population of 3781.

Bonnor had his workshop in print-works and bleachfields on the banks of the Leven, the water of which, from its softness and purity, is peculiarly fitted for the processes of printing and bleaching. Coals, lime, and other articles required in manufactures are brought up the river in large, well-built, roadway-bottomed lighters. The extensive works on the river are generally the property of mercantile houses in Glasgow. The Leven is celebrated for its fine salmon and trout.

Bonnor was the parish church of Bonhill there is a chapel-of-ease at Alexandria. At both places are chapels for Free Church and United Presbyterian Dissenters. There are also two chapels in Alexandria for Independents.

BONTO, the name of fishes belonging to the family Scromenidae. They are particularly common to the island of Bonaire, a part of the Antilles. [Thynicus, S. 1.]

BOOTE. [CUMBERLAND.]

BOUILLON, a house of vases belonging to the natural order Hydrocharidaceae, the species of which are eaten as pot-herbs.

BORAGE. [BORAGI, S. 1.]

BORDE DE SAINT-VINCENT, JEAN-BAPTISTE-GEOFFRAY-MARIE, was born in 1780, at Agen, in the French department of Lot-et-Garonne. As early as his fifteenth year he had addressed some communications to the Annals of the Society of Natural History of Bordeaux. In 1799 he accompanied Captain Malte-Brun, a naturalist, in an expedition which was sent out to Australia by the French government. In the course of the voyage, however, a disagreement took place between the captain and several of the officers and scientific men who accompanied him, in consequence of which Bory de Saint-Vincent and others abandoned the expedition at Mauritius, then named the Île de France. He was employed by the governor as one of the rat-major of the colony, and provided with whatever was requisite for making a survey of the adjacent islands. His residence of which Bory de Saint-Vincent and others abandoned the expedition at Mauritius, then named the Île de France. He was employed by the governor as one of the rat-major of the colony, and provided with whatever was requisite for making a survey of the adjacent islands. His residence of which Bory de Saint-Vincent and others abandoned the expedition at Mauritius, then named the Île de France. He was employed by the governor as one of the rat-major of the colony, and provided with whatever was requisite for making a survey of the adjacent islands. His residence

1. Carpels distinct or solitary
   Anthers with recurved valves
   Berberidaceae.

Anthers with longitudinal valves
   Style from the base of the carpel.
   Style from apex of carpel; fruit a legume
   Leguminosae.

2. Carpels wholly combined
   Placentas parietal
   Flowers with appendages
   Calyx in a broken whorl
   Elatinaceae.

   Flowers without appendages
   Leaves with round and oblong transparent dots
   Leaves dotless, circular when young
   Leaves dotless, straight when young; fruit capsular.
   Leguminosae.

   Leaves dotless, straight when young; fruit siliquose.
   Moringaceae.

   Placentas central
   Styles distinct
   Calyx in a broken whorl
   Elatinaceae.

   Flowers unisexual
   Euphorbiaceae.

   Flowers hermaphrodite
   Illiciaceae.

   Petals large; stamens hypogynous
   Malpighiaceae.

   Petals large; stamens perigynous; leaves opposite
   Osmundaceae.

   Petals large; stamens perigynous; leaves alternate
   Saxifragaceae.

   Styles more or less combined, not gynobasic
   Tiulaceae.

   Calyx in a complete whorl
   Gynobase fleshy
   Ochnaceae.

   Gynobase dry; leaves opposite
   Zygophyllaceae.

   Gynobase dry; leaves alternate
   Geraniaceae.

   Calyx not beaked
   Oxalidaceae.

   Styles more or less combined, not gynobasic
   Calyx in a broken whorl
   Vochysiaceae.

   Flowers spurred; flowers not spurred, calyculate, flowers not spurred, naked.
   Chilenaceae.

   Calyx in a complete whorl
   Sapiudaceae.

   Leaves compound; sepals more than 2
   Scrophulariaceae.

   Leaves simple; sepals about 2
   Malpighiaceae.

   Leaves simple; sepals 2
   Portulaceae.

   Calyx varying or open
   Sterculiaceae.

   Stamens columnar
   Fabaceae.

   Stamens not columnar
   Rhamnaceae.

   Stamens opposite petals
   Hypogynous
   Vitaceae.

   Stamens alternate with petals
   Vitaceae.

   Anthers porous.
   Chalillocarpaceae.

   Anthers slit; petals split.
   Anthers slit; petals undivided.

   Styles absent
   Berberidaceae.

   Leguminosae.

Fruit a legume; radicle away from hilum.
   Commardaceae.

Fruit not leguminous
   Crasulaceae.

Carpels with 1 scale
   Carocephalaceae.

Carpels with 2 scales
   Angiosperms.

Carpels without scales
   Embryon in vitellus
   Embryo naked
   Albumen solid.
   Albumen apocarpous.
   Albumen small or none.

Carpels several

   Leaves dotless
   Amaranthaceae.

   Anacardiaceae.

2. Carpels divided into a solid pistil

   Placentas parietal
   Stamens tetradynamous
   Cruciferae.

   Stamens not tetradynamous
   Flowers with sterile stamens
   Semitectum.

   Stamens and pistils on distinct flowers
   Pistil-flower crowned
   Papavaceae.

   Stamens and pistils not crowned
   Malesherbiaceae.

   Stamens and pistils together; placentas lining the fruit
   Oenotheraaceae.

   Stamens and pistils together; placentas in row
   Malesherbiaceae.

   Flowers without sterile stamens
   Disk of flower large
   Capparidaceae.

   Stamens indefinite
   Resedaceae.

   Disk of flower large
   Linaceae.

   Stamens definite
   Seed of flower small or none
   Papaveraceae.

   Stamens indefinite
   Albumen large
   Paeoniaceae.

   Stamens indefinite
   Calyx 5-leaved
   Turneaceae.

   Calyx tubular
   Framennsiaceae.

   Placentas covering dissipiments
   Nymphaceae.

   Placentas central
   Styles distinct
   Calyx valvate
   Viscaceae.

   Calyx in a broken whorl
   Rhamnaceae.

   Seeds hairy
   Brassicaceae.

   Seeds smooth; stamens polyadephous
   Hypericaceae.

   Seeds smooth; stamens monadephous
   Linaceae.

   Calyx in a complete whorl
   Saponariae.

   Carpels with a scale
   Carpathaceae.

   Carpels without scales
   Portulaceae.

   Calyx varying or open
   Saponariae.

   Stamens not arising from scales
   Saponariae.

   Styles united, gynobasic
   Styles combined; flowers hermaphrodite
   Rutaceae.

   Styles combined; flowers unisexual
   Xanthoyleaceae.

   Styles divided; flowers irregular
   Balsaminaceae.

   Flower regular
   Petals without appendages
   Acanthaceae.

   Petals with appendages
   Sapindaceae.

   Flowers papilionaceous
   Polygalaaceae.

Class, ENDOGENS.

1. Flowers complete (having distinct Floral Envelopes).

1. Ovary inferior
Flowers gynandrae

B. Ovary superior
Sepals calyx-like or glumaceous
Carpels separate, more or less
Placentas diffuse
Placentas narrow
Carpel in a solid pistil
Petals distinct from calyx
Placentas central
Placentas parietal
Petals not distinct from calyx
Flowers scattered
Flowers spadiceous

Sepals corolla-like
Carpels more or less separate
Seed solitary
Seeds numerous
Anthers turned outwards
Anthers turned inwards
Parts of flower 6
Parts of flower 2
Carpels combined
Petals rolled inwards
Petals not rolled inwards
Flowers with appendages
Flowers without appendages

II. Flowers incomplete (Floral Envelopes not distinct).

A. Flowers in glumes
Stems hollow
Stems solid

Carpel solitary; seed erect
Carpel solitary; seed pendulous
Carpels several, distinct
Glumes only
Cup within glumes
Carpels several, combined
Placentas parietal
Placentas central

B. Flowers, or with a few vertical leaves
a. Flowers on a spadix

Fruit a drupe
Fruit dried; leaves in bud
Convolute
Fruit dry; anthers clavate, on weak filaments

6. Flowers not on a spadix
Aquatic, with pendulous ovules
Pollen globe
Pollen convoid
Terrestrial; ovules erect
Aquatic; ovules erect

Sub-Class, Reticephal (Rhizanthae).

Ovules indefinite
Anthers opening by slits
Anthers bursting by pores

Ovules solitary

It will be seen that many of the orders are repeated in the analysis under different divisions; and this arises from the fact that this analysis is artificial, and only expresses the general characters of the plants. This is, in the strong- est, not, exceptions to some very general points of structure frequently occur. Thus we have apetalous and irregular-flowered plants in the polypetalous regular-flowered order Alismacoceae. With a little practice such an analysis as the foregoing will enable any one acquainted with the structure of plants to refer any particular plant to its right order, and re-turning to the order in the alphabetical part of the work, he will find a detailed account of its structure and properties.

NOTOBRYUS. [Bryopt.] 

BOTTLE-GOURD. [LAGENARIA, S. 1.]

BOULDERs. Of the materials of which superficial de- pths of debris of ancient rocks are composed, some are of large size, and have been called Boulders or Erratic Blocks. The portions of smaller size are called Gravel. Boulders are generally found not far from the rocks from which they have been broken, whilst gravel is carried to a great distance. Instances, however, are not wanting in which boulders have been transported an immense distance. They have been transported from Norway and Sweden to the plains of Germany, and from the mountains of Scotland to the centre and south of England. So large are some of these boulders, and the obstacles such as interfering hills, valleys, and seas so great, that the mode of their transportation can be accounted for in no other way than by supposing that they have been floated across them in some sea, which as they have melted or dropped in the places where they are now found when those places were at the bottom of a sea. The largest boulders seem to have drifted in all cases from northern and southern points towards the warmer districts in the temperate and tropical parts of the earth.

BOURMONT, LOUIS AUGUSTE VICTOR DE CHAISNE, MARSHAL COUNT DE, was born at Paris, or, according to other accounts, at the castle of Bournmont, in Anjou, at the year 1773. Having entered the army in 1788, at the age of sixteen, he served as an officer in the Royal French Guards until 1790, when he emigrated, and joined the army of the Prince de Condé. His sanguine disposition and earnest character recommended him so strongly to the emigrant prince that he was immediately employed in fomenting the insurrection of the western provinces. In October 1792, he was despatched by the Prince to the head-quarters of the Viscount de Scépeaux, under whose orders he commanded one of the corps of the Vendean troops, and was promoted to the rank of major-general. At this time he was only in his 21st year.

In December 1793 he was sent to England to endeavour to prevail on the British government to assist the Bourbon cause, but his mission proved abortive. He had the satisfaction, however, of seeing the Count d'Artois, afterwards Charles X., who received him in the most cordial manner, knighted him, and authorised him to confer the same honour on other loyal gentlemen adhering to the monarchical inter- ests, and more particularly on the Viscount de Scépeaux. He paid a second visit to England in 1796, exhibiting the greatest zeal in animating the French emigrants against the republic, and in collecting all the elements of civil war. Soon after he returned to France to share the perils of a new insurrection against the Vendee, and to superintend the ad- ministration of the Chouans in 1799. On the 16th of October of the same year he forced his way into Le Mans, the chief place in the department of Sarthe, committing it, asserted, great cruelties, pillaging the inhabitants of nearly a million of francs, burning the post-office, the public records, and the library in the Hotel-de-Ville.

About the period of the 18th Brumaire, when M. de Chaillot and other insurgent leaders found it necessary to submit to the civil government, the young captain de Bournmont followed their example. He strove to induce Georges Cad- doual to do the same; but that inflexible chief, far from complying,evinced his disgust at the proposal in 1801, by ordering Bournmont's brother-in-law to be shot. The active mind of the young soldier indisposed him to a life of ease; he therefore offered his services to Bonaparte, and appears to have exhibited more eagerness than discretion in so doing. The ever-vigilant Fouché suspected his zeal; he caused the Count to be strangled, and, having vanquished, he was advised to be considered sufficient proof of intended treachery, he sent him a prisoner to the Temple, Paris, in 1803. From this prison he was transferred to the citadel of Dijon, and thence to that of Besançon. Having escaped from this last place of confinement in 1810, he eventually returned to Portugal, where he remained for nine years. The French army having become masters of that country in 1810, Bournmont made interest with the victorious general, was included in the capitulation, and returned to France with the army. He now submitted fully to the imperial government of Napoleon, and was offered the brevet of colonel, which he accepted. It must be observed, however, that in the vindication of his career, published in 1840 by his son, it is stated that when the Count made his sub- mission he was at Nassau in France, and that he was allowed his liberty on condition of taking service in the army of Napoleon. His son goes so far as to assert that, in 1800, the First Consul offered him the post of lieutenant-general, which he declined.

From 1810 to 1814, Bournmont continued faithful to his new master; distinguished himself in several battles, especially at that of Nogent; and received no less than ten wounds, four of which were sabre cuts on the head. For this conduct he was rewarded with the rank of brigadier- general in 1813, and made a lieutenant-general the following year. When the fall of Napoleon tested the character of so many generals and marshals, Bournmont only followed the example of an almost universal defection. He did not betray Louis XVIII. in 1814; but, ever true to the use of his sword on the very eve of his departure from the Tuileries. After the flight of the King, he did not refuse to take service a second time under the powerful man, a single word from whom was enough to carry him. But he could not brook the despotism manifested in the Acte Additionnel, and tendered his resignation to the Emperor in
of which was formed at Standley, in Staffordshire, in 1810. This body, which in 1811 had two preachers and about 300 members, was formed by a number of Wesleyan laymen, who were local preachers, and 7842 members. In 1853 the connexion numbered 1789 chapels and 3565 rented rooms, with 566 paid travelling preachers, and 9564 local preachers. The members at the same time had reached 108,936. The dissolution of the Primitive Methodist Connexion, which was the Prin-

BOW

consequence of it. Receiving no answer, he left the French
army on the 15th June, 1818, after fully communicating his
desires to General Gerard and to Count de Bovront, to whom he
explained every requisite detail of the service. Marshal
Gerard, under whom he commanded a division during the
campaign, and General Hulat, have, since then, exonerated
Count de Bovront from all implication of treachery ; whilst Napoleon,
who now, in his account of the battle of Waterloo, does not
even accuse him. After his second restoration, Louis XVIII.
gave Count de Bovront the command of a division, in the infantry of his
Guard, and in this rank he served in the campaign of
1823, under the Duke of Angoulême in Spain; and on the
return of the Duke to France, he appointed Bovront to the
command of the army of occupation. In 1829 the portfolio of
the ministry of war was offered to him by Prince Félignan,
but he refused it, and the offer savoured of the compliment
of his more general in preference to himself, and was only per-
suaded to take office by the earnest request of the King.
In 1830 the great expedition to Algiers was resolved upon,
and the command of an army of 37,000 troops was conferred
upon Bovront. We have not space to follow his Algerian
career. But it must be noted as somewhat remarkable that
the man, who, in a few weeks, obtained for France this large
and valuable colony,—the principal conquest she has attained
during the present century,—should have been the object of
so much enmity. The reverse of his fortune, distressing as that unlike, and after Bovront had been
suppressed in his command on the 2nd of September, by
General Cisnau, a course was brought against the defeated
leader, and the public was gratified to find him
in one of the captured towns. One of his sons had
fallen in the campaign, and the custom-house officer at
Martille, after the landing of Bovront, carried his seal to
such an excess, as to examine the corpse in search for the
hidden gold; but this outrage patiently, but the Countess de Bovront received so great a shock, that she
ever rallied afterwards.

From the year 1850 Marshal de Bovront lived in exile; residing a time in England, Holland, Germany, and other countries. He was at one time, and was afterwards in France by Louis Philippe, and in 1840 he took up his abode with his family at the castle of Bovront. Here he con-
tinued to reside in the greatest retirement until the day of his death, which occurred on the 27th of October 1846, at
the age of 73. In France Bovront is, of all the republican
and imperial generals upon whom the charge of treason has
been affixed, the most unpopular. Neither Moreau nor
Pichegru, neither Bernadotte nor Marmont, has been so
famous. The early public denunciations against him are
only his second in obloquy. After a careful examination of
their real conduct, and due allowance being made for the
circumstances of the time, it would not require an unusual
strength of feeling much of that approbation which now
attaches to many of these great military men. But
the time to do it effectually is not yet past; and public
opinion must be respected even where it appears to

(Statistique des Contemporains ; Atlas, History of
Europe; Sarrut et Saint Edme, Notices; Feller, Dictionnaire
Historique.)

BOURNE, HUGH, the founder of the Primitive Metho-
dist Connexion, was born April 3rd, 1772, in the neighbour-
hood of Stoke-upon-Trent, in Staffordshire. He was
brought up in the Wesleyan Methodist communion, and
became an active and zealous preacher of that body. His
zeal appears to have carried him beyond the bounds allowed
by the leaders of the Wesleyan Conference, for when he
was about thirty years of age he associated himself with
William Clowes and some other preachers of the Wesleyan
body in reviving open-air religious services and camp me-
etings, or great gatherings for preaching and public worship.
Through these meetings, although conducted in the early
days of Methodism, and carried to very great lengths in
America, were disannounced by the Conference, which in
1807 passed a resolution to the following effect:—

"That this body does not wish to see any such meetings
(camp meetings) to be allowed in England, as they are held
improper in England, and likely to be productive of con-
siderable mischief, and we disclaim all connection with
them. This led to Mr. Bourne's separation from the
Wesleyan Conference, and the establishment of the Primi-
tive Methodist connexion, the first class or (local society)
archbishopal patronage," in great depression of spirits, 
Bowes made a tour through the north of England, Scotland, 
and some parts of the continent; and it was during this tour 
that he composed the "Sonnetts" which first made him known 
as a poet. The "Sonnetts" were intended for his own solace, 
and were not even committed to paper; but in 1789, when 
he had been some time back in England, it occurred to him, 
as he was passing through Bath on his way to Oxford, 
to copy them out, and send them to Bowes, the printer, to 
have them, and have them printed. Accordingly, he got Mr. 
Cruttwell, printer of a Bath newspaper, to strike off a hun-
dred copies at 40, under the title of "Fourteen Sonnetts.," 
and the expense of this modest publication was 5l. About six 
months after the publication he received a letter from Mr. 
Cruttwell, informing him that the 100 copies were all sold, 
and that he could have sold 500. Much encouraged (his 
hair was just dead, and his mother was in somewhat re-
duced circumstances), he printed a second edition of 500, 
adding some new sonnet; and some time afterwards a third 
edition of 750 was called for.

It is curious now, looking back, to think, that, in a year like 
1789, when France was in the throes of revolution, the 
publication from a provincial press of "Fourteen Sonnetts,"
by a young clergymen disappointed in love, should have 
ever been an event of any consequence in England; and yet it 
was. A new literary spirit, and new notions of poetry, were 
beginning to show themselves. Bowes' sonnet was not aimed 
at anything fresh and natural, even if but feeble, after the 
strong and fine artificialities, as they are called, of Dryden, 
 Pope, and their followers. Bowes' sonnets came at the 
 a series of poems with a prose autobiography introduced, 
published in 1737, in the author's seventieth year; and 
the "Village Verse-Book," published in the same year, 
and consisting of simple hymns composed by him for the use 
of the children of his parish. After 1789, Bowes did not publish 
much. Nor had any of his poems since "The Missionary," 
which is considered on the whole the best of his large 
works, greatly added to his reputation. In all of them they 
were the same; one might observe the same sensibility to 
gentle beauties; the same appreciation of the grand, 
the same power of cultural expression which had 
distinguished his first sonnet; but it was felt on the whole 
that he was a kind of feebler Wordsworth, whose poetry, 
so long as he chose to write anything, was always to be received 
with respect and dipped into at leisure than eagerly read 
and appreciated.

But the whole virtue of Bowes' life did not lie in his 
poems. He was also a very busy prose-writer. If the list of 
his prose-writings is left out, he wrote a number of works 
to prove considerable versatility on the part of the author.
The "Poet and Pope's Controversy," which lasted from 
1819 to 1838, if indeed it may not date from 1807, when 
Bowes' editorial attack as it was published, has a permanent 
interest in our literary history. It is the first of the prose 
time, between the old or eighteenth century school of 
English poetry and the so-called new or nineteenth century 
school. Bowes, while doing justice as he thought to Pope's 
true excellences, had made some reflections on his moral 
character, tending to depreciate it; and had also, in an 
append ed essay "On the Poetical Character of Pope," laid 
down this proposition, as determining the comparatively 
inferior rank of certain portions of Pope's poetry.--All 
these things are beautiful; more beautiful and sublime than images drawn from art, 
and are therefore more poetical; and in like manner the passions 
of the human heart, which belong to nature in general, are 
less adapted to the higher species of poetry than those 
which are derived from incidental and transient manners.." 
Byron in his "English Bards and Scotch Reviewers" had 
pilloried Bowes for what he had said of the moral character 
of Pope; but it was reserved for Campbell, when preparing 
"Scottish Poetry," to make this the first distinct contradiction to Bowes' critical theory of poetry. 
Campbell vigorously defended the right of the world of 
the artificial to furnish images to poetry, and instanced "ships 
"like the tears of the sea" as an example of what images 
might be. Bowes replied in his "Letter to the Invariable 
Principles," etc. Byron, then in Italy, wrote home to Murray 
that he was going "to plunge into the contest, and lay about 
him like a dragon, till he had made manure of Bowes for 
the top of Parnassus." He accordingly sent over two spirited
BOY

letters for Pope and Campbell against Bowles, to which also Bowles replied. Other critics, including Octavius Gilchrist and the Quarterly Review, took up the question on Campbell's manifold merits as one after another, restating his real views in opposition to what he considered misrepresentations of them, and supporting these views by reasonings and examinations of the reasonings and examples of his antagonist. For some time he stood alone; but at last, Richard and the Blackwood's critics came to his assistance, and maintained that on the whole he had had the best of the argument. This view is now generally acquiesced in. Bowles never said anything so absurd as that Pope might not hold opinion, which has been ignorantly palmed on him by some who have engaged in the controversy; he only laid down some critical canons determining the kind of much of Pope's poetry, as compared with higher kinds, of which fine examples were found, he said, in other poems of Pope himself, and pointed out the manner in which the more eminent of our architectural and landscape draughtsmen and engravers became acquainted for the execution of works of a higher grade in art. Mr. Bralyay himself contributed also to the progress of the fine arts in another direction. Having become acquainted with the late Henry Bone, R.A., who that artist was endeavouring to elevate painting in enamel to the position it subsequently acquired in his hands, as an integral and a legitimate branch of accepted pictorial art, he undertook the task of introducing it into the United States.

Enjoying repose in his old age after this battle, and looking round on such men as Rogers and Wordsworth as his junior coevals, and on younger poets rising in the room of the departed Coleridges and Southey's, and Scotts and Byrons, whose track lay within his own, and, a protracted life, Bowles survived to find himself almost forgotten in the midst of new persons and themes and interests. He had a presentation of this as early as 1837, when he wrote these words: 'Many years after my grey head shall have been laid at Bowes's feet, and his name has given place in the ranks of life, Bowles survived to find himself almost forgotten in the days of his eldest son so enthusiastically, may perhaps inquire Who was W. L. Bowles? The event thus anticipated came to pass on the 7th of April 1850, when Bowles died in the age of 88. His wife had died in 1844; and they left no family.

In his personal habits and manners Bowles was simple, genial, and kindly. He was also "famous," it is said, "for his Parson Adams-like forlornness." A life of him, the joint work of a relative and Mr. Alaric Watts, has been advertised as forthcoming; meanwhile we have gathered the above particulars from various notices, and from the autobiographical parts of his own writings. As we said at the outset, the subject is intertwined with interesting facts of some of his poems, particularly his Sonnets, and his Missionary and his Village Verse-Book, but with greater interest as a man occupying a position in our literary history entitling him in a manner to be called the 'Father of modern English Poetry.' If the designation is accepted, it must be allowed that he has had some very rebellious sons.

BOYLE. [Roscommon.]

BRACKEN. [Praslin, S. 1.]

BRADWIN. [Devonshire.]

BRAGHTIA, a genus of plants belonging to the natural order Aristolichaceae. One of the species, B. tenentos, is said by Dr. Horsfield to be intensely bitter, and to be used as a medicine in Java.

BRAIN. DISEASES OF. [Medicine, S. 1.]

BRAKE. [Praslin, S. 1.]

BRAKES ROCK, a common name for the Allisorma crispus, a plant belonging to the natural order Polyophytae. Allisorma is known by its nearly circular sori, which are at length confluent, and are concealed by the reflexed margin of the frond. A. crispus has a slender very brittle stem, which attains a height of from 6 to 12 inches. It grows in stony places on mountains throughout Great Britain.

BRANTFORD. [Canada, S. 1.]

BRAYERA, a genus of plants belonging to the natural order Rosaceae. One of the species, B. anthelmintica, yields the anthelmintic remedy known by the name Cassin, Cabot, or Sick's root. While the plant is anthelmintic, it is only known, it has only been recently introduced into Europe. The plant is a native of Abyssinia.

BRALEY, EDWARD WEDLAKE, F.S.A., a laborious and accurate topographer, was born in London (in the parish of Lambeth, St. Saviour) in the year 1725. He was apprenticed to one of the most eminent practitioners of the art of enamelling, but having from an early age been strongly addicted to literary pursuits, he gradually abandoned that business as a means of life, and devoted himself, a few years afterwards, to the study of the more congenial branch of professional literature. His acquaintance with Mr. Britton [Burton, John, S. 3.] had commenced before the expiration of his apprenticeship, and he also being desirous of exchanging a service occupation for the pursuits of literature, the two aspirants were associated in several literary undertakings of a minor description, until they united in projecting and in producing the well-known work on which their reputation was originally founded — 'The Beauties of England and Wales.' The Beauties of England and Wales were the most eminent of our architectural and landscape draughtsmen and engravers became qualified for the execution of works of a higher grade in art. Mr. Bralyay himself contributed also to the progress of the fine arts in another direction. Having become acquainted with the late Henry Bone, R.A., who that artist was endeavouring to elevate painting in enamel to the position it subsequently acquired in his hands, as an integral and a legitimate branch of accepted pictorial art, he undertook the task of introducing it into the United States.

In the year 1825 Mr. Bralyay was appointed librarian to the secretary of the Russell Institution, Great Coram-street, the third in date and in rank of the literary and scientific institutions established in London, which had been founded after seventeen years before to meet the intellectual requirements of the populous superior middle-class suburb which was the growing up on the estates of the Duke of Bedford and the Foundling Hospital, on the north side of the metropolis. It was the third librarian in succession of the Russell Institution, the first having been the late Nathaniel Highmore, L.I. and M.D. of Jesus College, Cambridge (author of 'Jus Ecclesiasticum Anglicanum,' etc.). In this capacity Mr. Bralyay greatly improved the library, and conducted with ability the general business of the institution, but without following the pursuits of a topographer and antiquary. He produced several catalogues of the library (the last in 1849 which are not however remarkable in a bibliographic point of view, but which have been largely useful). The principle of the analysis of collections is carried. Having singular strength of constitution, neither the wear and tear of these united official and professional vocations, nor the progress of age, sensibly impaired his faculties, either physical or mental, for many years. His most extensive work, the exception of 'The History of Westminster Abbey,'
BRI

The History of the Ancient Palace and late Houses of Parliament at Westminster,' 1836.

VISSARION HERBERT: - A Concise Account, Historical and Descriptive, of Lambeth Palace,' 1806.

BREAST, DISEASES OF. [SUSSEX, & C.]

BRIDGES. The requirements of railways have led, within the last few years, not only to the erection of stone and brick bridges and viaducts, of considerable and permanent character, but also to the construction of light and temporary bridges, such as the suspension, cable-stayed, or suspension bridge, which are useful as works of art, and interesting for their modes of construction, as many of them are, we do not intend here to speak. Our purpose is to notice some of those great iron bridges which have been constructed on novel or newly applied principles since the publication of the 'Penny Cyclopaedia' and 'Supplement.'

All the bridges we have to describe are applications of the girders. Crossing indifferently populous thoroughfares, and navigable rivers and streams, as well as streams and ways which commercial traffic seldom visits, the railway bridge or viaduct must often be of wide span, and so constructed as neither to impede traffic nor interfere with the public safety. Hence, neither the direction nor the level of the way can be materially considered, and the space to be crossed must be left as much as possible unbroken by divisions. The problem for the railway engineer, therefore, was to span the widest area with the least practicable elevation upon it, and in the flattest form, was soon found to be unsuitable. The readiest mode was to return to the most primitive. One of the earliest artificial bridges, if not the very earliest, was no doubt a bridging, or girders, whether that was the trunk of a tree or a plank matters not, laid across the stream, which with its ends resting on the banks or on artificial supports. And after the invention of the arch, the beam continued to be used for bridges as well as for innumerable purposes of architecture, and even showed the weakness of the beam, except within very narrow limits, and various methods were invented for strengthening it by the addition of diagonal and other bars or rods, technically known as bracings, stays, and trusses. Of these, trussed girders, as they are called, the general principles and applications, and the methods employed for determining their strength, ample accounts will be found in 'The Penny Cyclopaedia' articles, Tausiano, vol. 25, p. 318; Roors, vol. 8, p. 8.

Trussed-girders were very early employed for crossing railways across wide streets and streams. Among other instances, may be mentioned the bridge which carried the Blackwall Railway across the Minories, London; and several others on the Eastern Counties Railway, and the North-Western Railway. At first, the girders were commonly made of cast-iron, flanges being added to give greater strength; but the fall of the cast-iron girder bridge over the Dee at Chester led to the abandonment of that material, and the substitution of wrought-iron. The best distribution of the material has likewise been made the subject of the most careful study, and the very ingenious and elaborate experiments which have been devised in the course of the searching and protruded investigations instituted, have resulted in placing in the hands of the engineer a body of formula, applicable to almost every purpose on which he can be called to exercise his skill.

The principal varieties of trussed girders which have been adopted for railway bridges are the trellised, the bow-string, and the hollow-beam, or tubular: the application of which will be sufficiently illustrated in the Crumlin and the Byne viaducts; the Chestporth and the Saltash; the Great Western; and the Britannia and the Victoria bridges. We shall also notice an adaptation of the suspension principle to railway purposes in the Niagara Falls bridge.

The Crumlin Viaduct was constructed from the design and under the superintendence of Mr. T. W. Kennard, to carry the Newport Abergavenny and Hereford line across the valley of Crumlin, in South Wales, and to connect the above line with that of the Taff Vale. With its approaches, the bridge is 3,304 feet long, the roadway consists of seven spaces, each of 150 feet span, the roadway in the centre spans being at an elevation of 200 feet. The
entire structure is of iron. The piers which support the girders are composed of groups of thin cast-iron columns, each of 17 feet high by 1 foot in diameter, and arranged in tiers of fourteen columns each, cross-braced by wrought-iron ties and cast-iron struts. The central piers are 60 feet by 30 feet at the base, tapering upwards 24 feet by 13, and containing 140 columns, which are bound together by no less than 540 wrought-iron ties. At the top of each pier is a triangular frame of cast-iron, upon which rest the ends of the main girders. The girders themselves are strengthened by a complete network of wrought-iron ties and cast-iron struts, which would be impossible to explain clearly without diagrams, but which forms an admirable system of trellis trussing. There are four main girders to each span, to which six-inch planking is bolted for carrying the permanent way. The girders are bolted to the main girders by a symmetrical pin, which gives a complete appearance, yet seems to be sufficiently strong not merely to support the heaviest traffic, but to withstand the most violent storms. It was opened in May, 1867.

Another admirable example of the trellis-girder bridge is the viaduct which carries the Dublin and Belfast Railway over the Boyne, near Drogheda, and of which Sir John McNeill was the engineer. This noble work consists of a centre span of 364 and two side spans of 138 feet each. The bridge is about 12 feet above spring-tides, 90 feet clear. It was opened in April, 1855.

The High-Level Bridge, Newcastle-upon-Tyne.—Under Roover, 'Penny Cyclopedia,' vol. xx., p. 147, a cut and description are given of the simplest form of low-and-string iron rail. The combined use of wrought-iron and cast-iron struts, the application of the principle to girders of wrought-iron is noticed. For carrying railways over spaces of unusual width, or at a very oblique angle, bridges of wrought-iron bow-and-string (or bow-string) girders are occasionally required, and the bow-string girders were early found to be peculiarly suitable. Among others of an important character, it may be sufficient to mention an excellent one, which carries the North-Western Railway across the Regent's Canal, near the Camden-town station, and a great stone viaduct, by which the North London Railway crosses the Commercial-road at Stepney; and one, of rather peculiar form, on the Gloucester and Birmingham Railway at Cheltenham. But by far the most magnificent bow-string girders are by railway engineers usually called bow-string girders, and the bow-string girder principle, is the High-level Bridge which unites the towns of Newcastle-upon-Tyne and Gateshead.

When the Newcastle and Berwick Railway was planned, it was felt that a junction with the Newcastle and Darlington line could be effected only by the construction of a very lofty bridge over the Tyne at Newcastle; because the banks of the river at that spot are very steep, and the general level of the railways would not permit of a crossing at a relatively small height above the water. It had long been wished by the Newcastle subscribers for a bridge, but a splendid old bridge was adapted only for the low or water-side districts of Newcastle and Gateshead; and Mr. Robert Stephenson boldly designed a scheme which should meet this requirement. The bridge, which runs entirely across the railway, is a work of the celebrated engineer, and was begun in the year 1839.

His plan was to have a double bridge, with a railway line over a common road. The railway companies and the town corporations assented; an Act was obtained; the works were actively commenced about the beginning of 1847; and the bridge was opened by the Queen in person in September, 1849.

The width of the river at this spot is 615 feet; but from the high ground in Gateshead to that in Newcastle the distance is about 1300 feet, and the river measures 138 feet. Four piers of massive masonry rise from the banks of the river, and one from each bank; besides minor piers to support the roadway on either side. The superstructure consists of two platforms, an upper, carrying three lines of rails; and a lower, which forms the public road. The lower platform is about 90 feet above the high-water level; the upper is 20 feet higher. Either span or bay of the bridge is crossed by four main cast-iron arch ribs, with horizontal timber struts. These ribs are disposed in pairs—the two inner ribs being placed a span apart, and forming the carriage road; while between the inner and outer ribs is a space of six feet, which is used for foot passages. The upper, or railway, platform rests upon the arch ribs, and is carried by being supported on the wrought-iron rods. Each arch rib was cast in five segments, which, when put together, gives a span of 125 feet, with a rise of 18 feet. Besides the tier or tension bar, the ribs are braced by horizontal and vertical bracing frames, while diagonal bracings are inserted in the spandrels, or spaces between the arches and the girders which carry the railway.

On the tops of the spandrel pillars, girders extend lengthwise, from which others stretch at right angles across the archedrib. The whole has thus a perfectly rigid character, and is found to bear the heaviest weights without deflection. Altogether, this bridge is one of the finest engineering works of our time, though eclipsed in magnitude by the vast work, by the same engineer, which we are about to describe.

When the railway was opened, the bridge was to carry the Chester and Holyhead Railway across the Menai Strait, from Bangor to the isle of Anglesey. As the Menai Strait is navigable by shipping, the Admiralty Commissioners refused to sanction the construction of a bridge, and it was decided to make a canal for ships at least 100 feet in height. Mr. Stephenson at first proposed to meet the requirements of the Commissioners by erecting an iron bridge of two immense arches; but his plan proposed that the arches should be 100 feet high at the centre, and only 50 feet at the spring of the arches, and the Commissioners refused to permit it to be executed unless he raised the level so that the spring of the arches should be 100 feet above the water. As this would have compelled the height of the bridge to be over 190 feet, the idea was abandoned, and intention, and boldly resolved to cross the channel by a girder bridge. He found a site about a mile on the Caernarvon side of the Menai, where the land is not only low, but also the banks of the river are very steep, and the whole stretch rises from a height of 140 feet. There seems to have been no such low land at the opposite end, but there is a slight rise from the river to 100 feet high, where the land is rather high. The bridge is to be commenced this year, and it is expected that, when completed, it will be a magnificent work of art, and a great addition to the utility of the country. It will be a very valuable addition to the transportation facilities of the northern part of England. It will be a very valuable addition to the transportation facilities of the northern part of England.
east and west towers respectively, and are constructed of massive masonry.

The towers: these presses, like many other parts of the apparatus, were larger and more powerful than any before constructed. The steam-engines of the time were so weak that the power each worked the presses; the presses gradually drew up the chains, and the chains carried up the tube; when the masonry was built up under the tube, the end of which moved within a groove left for the purpose in the tower.

The two towers were connected for the purpose of conveying water from the river. Two steam-engines of the time were placed across the bottom of the tower, with a connecting pipe between them. The whole was strengthened by arches, and the upper part of the tower was strengthened by arches, and the upper part of the tower was accordingly built of stone, so as to support the weight of the press and the equipment.

The first stone of the Britannia tower was laid in May 1846, on the 21st of October, 1850. Subject to the severest tests with trains loaded to the extent of 300 tons, the tubes did not exhibit a deflection more than 2 inches. They have now been subjected for more than seven years to the strain of traffic and the fury of the elements without any appreciable permanent influence having been produced upon them, or any perceptible increase of deflection.

The architecture of the towers is that of the Victoria Bridge, Canada.—A more remarkable bridge is to size and in many other respects than that over the Menai Strait of a similar superstructure is the Victoria Bridge of the Grand Trunk of Canada railway, which is in course of construction across the St. Lawrence, near Montreal, and is expected to be completed in 1859. From shore to shore of the St. Lawrence, the Victoria bridge will be nearly two miles in length, being about five and a half times the length of the Britannia Bridge. It will be a single span of 400 feet, the length of Waterloo bridge, London. The tubes, which are similar in construction to those of the Britannia bridge, will be supported on 24 piers, of which 14 were completed in December, 1857. The abutments have also been completed for the tubes, and the whole will be of cast-iron. The length of the bridge is 245 feet, the central span being 330 feet, and 50 feet above the summer level of the St. Lawrence. The length of the bridge between the abutments is 6000 feet. The engineer is Mr. M. Ross.

Chepstow Bridge.—In this bridge, which carries the South Wales railway across the river Wye, near Chepstow, Mr. Brunel has employed two kinds of trussed girders, and also applied the rigid suspension principle. In one portion of the bridge wrought-iron girders 100 feet in span, and of the ordinary form, rest on cast-iron columns; while in the other portion, which is 305 feet in span, the trussed girders are supported by chains, the tension of which is resisted not in an ordinary suspension bridge, but by being transferred to a horizontal wrought-iron column or strut, 9 feet in diameter and 3 feet 6 inches in thickness, which rests on the towers at the ends of the bridge. The chains consist of three straight links only—its rigid form being maintained by the horizontal column prevented by vertical and diagonal bracings: the chain in effect is converted into the lower member of a rigid girder. The girders which carry the road have only two points of suspension, one at each end of the bridge, and they are provided for by the horizontal wrought-iron columns. These girders are 56 feet above the ordinary low-water level, but owing to the remarkable rise of tide here, only 46 feet above high-water. The towers at the ends of the bridge present no peculiar features, but the middle one rests upon a pier formed by six enormous cast-iron
cylinders which pass through 50 feet of soil to the solid rock beneath. They were sunk to their positions by the removal of the soil. The towers (in their present form as the foundations of Rochester bridge were formed), fresh cylinders being added as the previous ones sunk down. They were then filled up with concrete, and eventually carried up to a height of 190 feet, when they were bound together by the chains which attached to the horizontal ties.

A somewhat similar combination of the rigid suspension bearing with the tubular form is being carried out in Mr. Brunel's *Royal Albert Bridge*, at Salasah, near Plymouth, which is designed to carry the Cornish and Devon railway across the river Tamar, in order to connect it with the South Devon line. The total length of this bridge is 2200 feet, the principal spans are each 455 feet, and the height of the railway above high-water level is 100 feet. The centre tower is built up to a height of 126 feet above high-water mark, upon this rest four octagonal cast-iron columns which carry the standards upon which one end of each tube rests; this tower rises to a height of 240 feet above the foundations.

The principal side piers are of solid masonry, and carry the bed plates and rollers upon which rest the other ends of the tubes, and which permit their free expansion or contraction under the influence of variations of temperature. The tubes are similar in principle to those of the Britannia bridge, and like it are of cast-iron. Each side was floated out on pontoons to a spot between the towers, and thence gradually lifted by hydraulic pressure to their ultimate position.

*Niagara Falls Suspension Railway Bridge*—The most remarkable application of the suspension principle yet made to railway purposes, has been made in the bridge constructed across the Niagara river, by Mr. J. A. Roebling, in order to carry the railway, and also the ordinary carriage and passenger traffic across that river. The space to be crossed was above 820 feet, and the level above the water 245 feet. From the nature of the locality it was necessary that the bridge should consist of a single arch or span, whilst the erection of scaffolding or the floating of portions of the structure in water was impracticable, and hence a suspension bridge appeared to be the only available form of structure. But any other than rigid bridges had been shown to be unsuitable for railways, and it became necessary to overcome the flexibility inherent in suspension bridges of the ordinary kind. This the engineer has successfully accomplished, and the bridge which links the British possessions with the United States is, confessedly, one of the most remarkable achievements in modern engineering.

The main beam, also in form, 25 feet wide at the bottom, and 24 feet at the top, 18 feet high and 821 feet long from the centres of the towers. Along the bottom floor the ordinary passenger traffic is carried; along the top runs the railway. Separate systems of wire cables, two sets, each of 13 inches, are supported by three sets of roadway, which are constructed of timber beams. The roadways are connected by double trusses so arranged that their resistance acts in opposite directions, upwards as well as downwards. The beams of the two floors are connected by posts which serve to transmit the depressive action of loads from one floor to the other. The posts are trussed together by diagonal rods. By these simple arrangements in combination with the tubular form of the bridge, a considerable increase of rigidity is obtained. To maintain horizontal stability the upper cables are braced laterally, and there are diagonal stays of wire above and below the floors. Fifty-six stays from the lower floor at the ends of the bridge are strung from the upper one to the rock.

Further, the cables, expansion and contraction from variation of temperature, high winds, &c., is needless to say careful provision is made. The railway traffic passes along the centre of the upper floor, the common waggons traffic along each side of the lower floor. The anchorage was commenced in September, 1852, the bridge was opened for traffic in March, 1855. The total cost was under 400,000 dollars. The bridge answers its purpose perfectly; but it must not be supposed that the suspension principle for railway bridges, except under peculiar circumstances. In this case the river being un navigable, the engineer has been able to obtain stable rigidity by the use of an extended series of stays below the roadway, securely fastened by anchor chains on the bed of the river; of course in exceptional cases. And although by the judicious application of the tubular form, and the use of a happy combination of trusses, girders, stays and weights, a remarkable amount of rigidity has been obtained, it is yet considered unsafe to allow the passage of trains over it in less than three miles an hour. At that rate when a train of 326 tons is passing over it, the bridge only cambers to the extent of 10 inches, and the roadway assumes its original level immediately the train has passed.

Application of Suspension to Railways—The applicability of the suspension principle to railway bridges is about to be further tried by an English engineer. For some time this subject has been in various forms under investigation, and at the last meeting of the British Association for the Advancement of Science, before the section of Mechanical Science, in which he stated that the suspension bridge which he erected in 1862 over the river Dniester, at Kieff, in Prussia, and to the platform of which he gave great rigidity by a careful system of bearings and cross-beams, he had, amongst other things, which had been exposed, but had successfully withstood the severest tests in the passage over it of Russian armies with heavy ordnance during the recent war in the east.

As a result of his experience with his bridge on other inquiries, he had arrived at the conclusion that the adaptation of suspension bridges to railway purposes is quite practicable if the speed of trains when passing over them be moderate as compared with the ordinary speed on railways, to which end he has designed a girders bridge to be supported by suspension chains, for the purpose of unifying the Londonderry and Enniskillen and the Londonderry and Cole-raine railways. The importance of the question in a question of so acute as this will be well understood by Mr. P. W. Barlow, who is constructing a girders bridge, to be supported by suspension chains, for the purpose of unifying the Londonderry and Enniskillen and the Londonderry and Cole-raine railways. The importance of the question in a question of so acute as this will be well understood by Mr. P. W. Barlow, who is constructing a girders bridge, to be supported by suspension chains, for the purpose of unifying the Londonderry and Enniskillen and the Londonderry and Cole-raine railways. The importance of the question in a question of so acute as this will be well understood by Mr. P. W. Barlow, who is constructing a girders bridge, to be supported by suspension chains, for the purpose of unifying the Londonderry and Enniskillen and the Londonderry and Cole-raine railways.

*Foundations of Bridges*—To our notice of new principle in constructing the superstructure of bridges, it may be necessary to call the attention of our readers to one of the most important of the new expedients adopted in forming the foundations. Until recently, in order to build the foundations of piers and abutments of a bridge under water, one of two plans was adopted: the first was to place the supports around the site of the pier, a soffit, or wooden waist, eight or ten feet in width, from which the water was pumped out so as to allow a firm and dry foundation to be laid;—this was a plan adopted at London and Waterloo bridges and in my other bridges of an important character; the other, and much less costly, though less stable method, was to surround the platform on which the foundation of the pier was built with water-tight sides, and thus make a large water-tight be used to carry away the water by means of an engine, only its proper level could be detached, the bottom or sides remaining as a foundation—this was the method used in constructing the piers of the old Westminster bridge.

[Editorial note: *Fenny Cyclopaedia,* vol. vii, p. 2894.]*] Coffer-dams and caissons were of course modified in form, according to circumstances, and the method of construction according to the views of individual engineers; but wherever used they have been the same principle. A more economical and less tedious system of which should be equally durable, has long been desirous of being tried, and was eventually adopted by Sir George grosse, and is now being tried. Some of these have been successfully carried out in practice, as far as construction goes, where seems no reason to doubt their permanent stability in connection with the united country and on the continent, where so far from having been dispensed with. Piles and concrete, cast in situ
has the property of setting under water, the concrete being deposited through the water by means of shoots. The casing was previously tied together, across the intended pier, by iron bolts. This system of construction was to terminate at or close to the level of the heavy capstones of granite to be fixed over the piers, concrete to be cast in position, and the whole to be levelled off to receive a heavy bed of granite capping, or rather base course, above which the pier would be continued in brickwork faced in granite, to finally enclose the base, the two principal arches of the bridge. The works in course of execution are of course retarded by the rise of the tide; but otherwise, though below water, they are conducted above it, except as to the requisite inspection, the attachment of the iron ties, and in some cases where the diving-bell or the diving-dress is used.

The 145 bearing-piles in each pier of Westminster bridge are driven to an average depth of 39 feet 6 inches below low-water line; the cast-iron piles, 10 feet in length, are driven 33 feet 9 inches below the same line, so that their heads stand somewhat above it; the 44 cast-iron plates or flat sheeting-piles, 15 feet in length, are driven down to 21 feet below low water, and to make up the height, they are surmounted by granite slabs, which, consequently with the upper part of the round piles, are part of the casing. The bearing-piles are thus 22 feet below the average level of the caissons of the old bridge, and the caisson-piles are respectively 16 feet 9 inches, and 14 feet below that level. Sourthernly of the bridge, the bearing-piles intended to be provided by a solid mass of concrete round the pier; this concrete when set forming a kind of artificial rock, which is found to be harder than the granite of the old bridge, on which a trench is dredged out to the clay, and it is proposed that it shall have a thickness of five or six feet; so that, should it endure, as the hardness and heaviness of the mass would make probable, the flat piles would be always underground, and at the direction at the feet of the piers, there could be no escape of the gravel. Mr. Page further proposes to dredge out the channel under the arch to a regular curve, commencing at three feet below low water at the piers, and increasing at the rate of a rectangle, in depth there of about 12 feet; and he believes from his observation of the flow of the stream of the tides, that the tendency would not be to scour at Westminster bridge, but that the first operation would rather be to sit up the entire cost of constructing the foundations of the new bridge on Mr. Page's system is estimated at about 60,000l. less than by the employment of coffer-dams. A peculiarity in the construction of the new Westminster bridge is that, in order to use the expense of the temporary wooden bridge when a new bridge is to be erected on the site of an old one, only one half of the bridge—the western—is in the first instance to be built alongside of the old structure, which is during its progress to be used for the ordinary traffic of the new bridge. The old bridge used for traffic, the old bridge is to be demolished, and the other, or eastern half of the new bridge erected on its site. This necessitates the construction of the piers, as well as of the bridge itself, in two parts, at intervals of time, and doubtless have been constructed whether there is not in consequence likely to be unequal settlements in the completed structure. Mr. Page has, however, suggested arrangements for the formation of the piers, and for the introduction of peculiar bracings in the coupling together of the two parts of the superstructure which will afford sufficient provision for any inequalities of subsidence.

In the system of Mr. J. Hughes employed in forming the foundations of the Town and Railway bridges which cross the Medway side by side at Rochester, the piers are entirely supported on cast-iron cylinders, which were sunk down to the hard chalk by using each cylinder as a diving-bell. A somewhat similar principle has been applied to other bridges, and there are different claims to the invention of the principle. In the original invention of Dr. Potts, the sinking of the cylinder was effected by the exhaustion of the air contained within it, but though that method has been adopted in some cases, it has not met with general success. Mr. Crewe's invention of the compressing of hollow cylindrical piles through sand by means of compressed air, to M. Triger, who thus sunk a shaft through a quicksand 65 feet thick, on the banks of the Loire. But the actual use of cylinders, which are known as diving-bells in which the workmen carry on their operations, the diving-bell then forming a part of the permanent structure, is an
extension of the principle which is due to the ingenuity of Mr. Mllitchell. The Railway and Town bridges are both borne on abutments at the banks, and two piers in the bed of the river. To sustain the abutment on the Srood side 30 hollow cylinders were used; for the Rochester abutment 12; and for each of the two piers 14; making in all 72 hollow cylindrical piles, each 7 feet in diameter. The piers are respectively 70 feet long and 17 feet wide, and the cylinders are set at distances of 9 feet apart lengthwise, and 10 feet transversely. The bed of the river was found by boring to consist of clay, sand, gravel, and hard chalk, which appeared at a depth of 44 feet below high-water level. On this hard chalk the cylinders were to be based. To reach it for the Srood pier a mass of hard stone, partly rock and partly original bridge, had to be passed through. The plan of sinking hollow cylinders by explosion was evidently impracticable here. To ensure a firm foundation workmen must excavate the stone, gravel, &c., in order to prepare a passage for the descent of the cylinders, and then to secure their stability fill them with brickwork as soon as they were in the positions they were ultimately to occupy. The cylinders were in lengths of 9 feet each, the diameter as already mentioned being 7 feet. Operations were carried out in the following manner: each hollow cylinder into a diving-bell, by securely bolting to one end of it a wrought-iron cover. Through this cover were two cast-iron air-locks (or chambers bearing a certain resemblance of a casing of a casement). These doors, through which the workmen entered and quitted the cylinder, the excavated materials were passed out, and the brick and concrete passed in. Separate copses, one under the control of a workman inside, the other under the charge of a workman outside, permitted the passage at will of the buckets outwards or inwards, the filling of the chamfer with compressed air, &c. There was besides a great number of ingenious appliances for the convenience of the workmen intended to facilitate the various operations, which it would be out of place to describe here. The account is fully described and illustrated in Mr. Hughes's Memoir on the subject, and in the Supplement (1856) to Mr. Crasy's 'Encyclopedia of Civil Engineering.' A substantial timber stage having been erected over the site of the pier, and steam-engines and air-pumps conveniently placed, the prepared cylinder was connected with an air-pump, and with various apparatus was lowered to the proper position on the bed of the river. The working of the air-pump was continued by motion, the flap of one of the air-locks and the door of the other being closed, a few strokes compressed the air within the pile [or cylinder] sufficiently to seal the joints; and every several strokes an additional quantity, until the density was sufficient to expel all the air that was above the bottom dry. Fifteen feet of water was cleared out in five minutes; and whilst the pumping continued the workmen passed through the air-locks to their respective stations; and as the excavations proceeded, the material, sent up in buckets, was discharged into lighters placed alongside. During the time of shallow water, the pile descended as rapidly as the excavations below would permit it; but when the water was deep, and the weight of the pile and elasticity of compressed air contained in it were nearly in equilibrium, the excavation was carried down 14 inches below the edge of the pile, when it would at once descend through the whole space as soon as the pressure was removed. The description of this process will be found in the Supplement (p. 1697). When the cylinder had thus sunk 9 feet, the cover, with the air-chambers, was lifted off, and another 9 feet length of cylinder was bolted on to the first, the air-locks being now fastened to the top of the upper cylinder. The air-pump was again set to work, the excavations proceeded, the process was repeated, and the cylinder sank another 9 feet. These operations were repeated till the necessary depth had been reached, when the cylinders were filled up with brickwork and covered with mud. In the nine lengths of cylinder employed. The lowest remained unshaped; the one above it was surrounded by soft chalk; the third by Kentish rag stone; while about half of the fourth was above the bed of the river.

BRITTON, John, was born July 7, 1771, at Kingston-St. Michael, near Chippenham, Wiltshire, where his father was a small farmer, and kept a village shop. His parents, dying early, he was received as a servant by an uncle in London, who after a while apprenticed him to a wine-merchant. After having served six years, his health gave way, and his master agreed to cancel his indentures. Young Britton, no doubt, expected little rudimentary instruction, and during his apprenticeship he had become extremely fond of reading, but his reading was desultory and aimless. On reaching manhood he was still uneducated, and the instruction he received from his master was rare and haphazard, &c., and at length adventured on writing an 'Account of the Surprising Adventures of Pizarro.' Some short notices which he prepared for the 'Sporting Magazine' brought him acquainted with Mr. Whaleb, its publisher, and to the connection thus formed Mr. Britton owed his introduction into the career which he so long and honourably pursued.

Mr. Whaleb, whilst residing at Salisbury, had issued the prospectus of a work to be called the 'Beauties of Wiltshire,' and he wished the author to make a tour for the purpose of procuring local materials. When, however, Mr. Britton's acquaintances was a young man named Brayley of about his own age, but somewhat better taught; they had assisted each other in their studies, and were prepared to enter upon a sort of literary partnership. In conjunction with his friend Brayley, Britton promptly undertook to get up from ready sources an 'Account of Wiltshire,' and as their first preparation for it, the friends set out on a tour, not, as might be supposed, through Wiltshire, but through Wales. In due time however 'Beauties of Wiltshire' were completed in 2 vols. Svo (1801), to the satisfaction of the publishers; and at their invitation the joint authors immediately set to work on the 'Beauties of Bedfordshire.' Brayley had long been familiar with the history and antiquities of the county, and Britton commenced in 1802, and were published in 26 vols., but only the first nine volumes were written by the original authors. [Brayley, E. W., S. 2.] While compiling his 'Wiltshire,' Mr. Britton not only became conscious of his deficiencies, but endeavoured resolutely to supply them; and he criticizes the ignorance of various antiquaries and topographers with whom the work brought him into connection materially assisted his progress. Finding his publisher averse to the admission of antiquarian matter, he began to collect materials for another and more elaborate work. At this period he also published the 'Antiquities of England,' of which the first part was published in 1806, and which was above nine years in progress. It eventually formed five splendid quarto volumes. Henceforth Mr. Britton's course was occupied with the exercise of his peculiar powers, as an enthusiastic authorship in the path which he made for many years in a special manner his own—that of architectural and topographical description and
antiquities. It would occupy too much space to enumerate his many publications, which in his own chronological list, is, to the best of our knowledge, the number eighty-seven distinct productions. The most important of them is the 'Cathedral Antiquities of England,' a magnificent work, which was commenced in 1814 by the publication in a detached form of the 'Antiquities of Salisbury Cathedral,' and was continued by Cradock, and was completed, and includes the entire cathedrals of England. In its completed form the 'Cathedral Antiquities' occupy 14 vols. fol. and 4to, 1814-35, with upwards of 300 highly finished steel-engravings.

The production of these works was carried out throughout a period of extreme impoverishment, many of the artists working in his own house, and being trained to their work by himself; and the facility he thus acquired in the production of this class of publications led to the preparation of many other, of which among the illustrated works of which he was either author or editor may be named—an 'Historical Account of Cromham House,' 1806; the 'Fine Arts of the English School,' 1810; 'Historical and Antiquarian Collections of the City of London,' 1820; 'Architecture of the Middle Ages,' 1822; 'History of the Ancient Palace and Houses of Parliament at Westminster,' jointly with E. W. Brayley, 1824; 1824-36; 'Historical Account of the Ancient Seis of Windsor Castle,' 1842; &c. &c. Besides these Mr. Britton wrote on many subjects connected with literature, either as distinct works or as contributions to literary journals, &c. In biography he published in 1844 'A Memoir of John Aurey,' and in 1848 an essay entitled 'The Authorship of the Letters of Junius Excidiat, including a Biographical Memoir of Colonel Barré, M.P.' Mr. Britton wrote the articles 'Avery,' 'Stonehenge, and the Druids,' and 'Tintagel,' for the 5th edition of the 'Encyclopaedia'.

In 1847 the literary and other friends of Mr. Britton gave the veteran author a dinner in his retirement from the active pursuit of his calling; and it being determined to mark their esteem for him by a permanent testimonial, a social gathering called the 'Britton Club' was organized to carry out the project. The form of the testimonial, at Mr. Britton's own suggestion, it was eventually agreed should be an 'Autobiography,' which he was to prepare to and print with the testimonial funds. Despite of his advanced age, Mr. Britton undertook the imposing task of collecting and preparing the parts of his 'Autobiography' were published, but he died before the work was completed, January 10, 1857. Mr. Britton was not a man of marked originality or great mental power; but he gave the world a writer in a branch of literature which had been cultivated chiefly by minute antiquaries, he did excellent service in calling the attention of the educated public to the long-neglected topographical and architectural antiquities of England; and there can be little doubt that his elegantly-illustrated works have been a chief exciting cause in bringing about the improved state of public feeling with reference to our national antiquities. The career of Mr. Britton was moreover an admirable illustration, as he himself describes it, 'of what may be effected by real and industry, with moderate talents, and without academic learning.'

BROCKVILLE. [Canada, S. E.]
BROMAL. [Chemistry, S. I.]
BROMLEY. [Abbots.]
BROMLEY. [Staffordshire.]
BROMUS, a genus of plants belonging to the natural order Gramineaceae, and the tribe Festucce. It has unequal many-mowed herbaceous glumes, the lower being 1-nerved, the upper 3-nerved. It is an essential species in wire grass, and is often a weed in various places. The outer palea short, (usually) founded on three spurs from below the tip. The styles below the summit of the fruit lateral. The sheaths of the leaves divide half way down. The species are generally brown or black, and are embraced in a series of elaborate illustrations of the plant. Four of the species are common in Great Britain. B. erectus has an erect stem two or three feet high, and grows on dry sandy and chalky soils. It is known from the other species by the outer palea being indistinctly 7-nerved and one-third larger than the smaller glume.

B. epur has its outer palea hairy and 5- to 7-ribbed, with the leaves broad and hairy. The stem reaches a height of four or five feet. It grows in damp woods and thicket.

B. ramaris is a plant and is known by its outer palea having 7 distinct equidistant ribs. It has large flat broad pubescent leaves, and a stem from one to two feet high. It grows in waste places.

B. ciliatus is remarkable for its erect panic. It is a rare plant.

Some of the species, as B. purpurea and B. catharticus, are purgative, whilst B. mollic is said to possess poisonous properties.

BRONNYARD. [Herefordshire.]
BRONIGNART, ALEXANDRE, an eminent chemist and mineralogist, son of the architect of the Invalides, was born at Paris in 1770. He received a good education, promoted by his father's care, and the friendship of Lavosier and of the well-known Franklin; and in 1791, delivered a lecture on chemistry before he was fifteen. He pursued his earliest scientific studies at the Ècole des Mines, and at the École de Médecine. At the age of nineteen he assisted in establishing the Société Philomathique, and in 1795 he visited England for a scientific examination of the mines, and collecting minerals and rocks of Derbyshire. One of the results showed itself on his return to France by his publication of a 'Mémoire sur l'Art de l'Émailleur,' in which improvements were suggested. It was then between the year 1795 and 1797, that he came to London, who was chemical demonstrator at the Jardin des Plantes.

The requisition for military service which called every Frenchman to the front, Bronignart was attached as apostle to the army of the Pyrenees, and for fifteen months he served, which enjoyed during this period, without detracting from his studies of the botany, zoology, and geology of the country. Having however been suspected of favouring the escape of the naturalist, Bronsonnet, he was imprisoned; but the news of his freedom restored him to liberty. He returned to Paris, and was employed as an engineer under the Agency of mines. Next he was chosen professor of natural history at the École Centrale des Quatre Nations; and in 1800 he was appointed director of the porcelain factory at Sèvres, which latter office was afterwards given over to his pupil who was now known to be a gentleman of such learning and consequence as to be able to carry on the study of mineralogy and of chemistry with the best possible results.

In 1807, at the instance of the Imperial University, Bronignart published his 'Traité élémentaire de Minéralogie,' which is described as "one of the best, and in particular one of the clearest and most practical" then known. It became a textbook for lecturers; and it exhibits the originality and lucidity of the author in the early years. Pursuing his zoological researches, he studied the freshwater formations of Anverge, and revisited England to study the corresponding formations of this country. It was he who established the four divisions of reptiles, and he was the first who distinguished the class of birds, and the class of Ophidiens, by which they are now familiarly known. To him naturalists owe the name Trichôte, and a basis of classification for those singular Crustacea. It has been the starting-point for all subsequent works on the subject.

Bronignart's studies rendered him the congenial associate of Cuvier; he helped to classify the Montmartre fossils, and in 1810 appeared the joint publication 'Essai sur la Géographie Minéralogique des Environs de Paris.' It was reprinted in the following year, with important additions, and has since been recognized as the classical type of similar works. It confirmed Bronignart's reputation, and in 1816 he was elected a member of the Academy of Sciences of the Institute, and a foreign member of the Royal Society of London.

In 1817, accompanied by his son and one of his pupils, he made a scientific tour to Switzerland and Italy, during which, by his discoveries and generalizations, he strengthened his claim to be regarded as the legislator in fossil zoology. 'All the new results obtained were inserted in the third edition of the 'Essai,' published in 1822. In 1824 he travelled to Sweden, and with Berzelius for his companion and interpreter, laid down the first foundations of a classification of the fosse, and for the first time recognized that the earth was a memoir on the erratic blocks. He afterwards put forth his clear and ingenious views on volcanoes, particularly of Vesuvius, and an original memoir on the 'Ophiolithes of the Apennines.'

With all this activity Bronignart did not neglect his duties as director of the national manufacture of porcelain; his
journeys and labours to acquaint himself with the best pro-
ounced materials and methods would alone have sufficed to occupy
any ordinary man. The results of his long experience appeared
in 1845 in his "Traité des Arts Cinématiques." And carrying
out his earliest researches on enamelling, he revived at
Sèvres the almost lost art of painting on glass. He found
time and opportunity to share in the undertaking of edu-
cation, and in promoting the interests of science, and the views
of scientific inquirers. He died on the 14th of October, 1847.
Brounart was a foreign member of the Geological Society of
France, and other learned societies. His writings are to be
tion minérale de Roches mélangées," 1813; "Mé-
moire sur les Corps organisés fossiles nommés Tribolites," 1814; "Histoire Naturelle des Crustacés fossiles sous les Rap-
ports zoologiques et géologiques," 4to, 1822 (jointly with
Desmarest); "Introduction à la Minéralogie," 8vo, 1825.
Tableau des Terrains qui compose l'Ecorce du Globe," 8vo,
1839; "Premier Mémoire sur les Kaolins, sur Argiles à Por-
celaine," 4to, 1839; "Second Mémoire sur la Nature et les
Geo. Soc.)
BRONTÉ, CHARLOTTE (Mrs. Nicholls, better known by her pseudonym Currer Bell), was born April 21st, 1816, at the parsonage of Blackham, near Gisburn, Yorkshire, of which her father, the Rev. Patrick Bronté, had held the living. He afterwards held the living of Haworth, also in the West Riding, about four miles from Keighley. Mr. Bronté removed from Haworth to Haworth February 25th, 1820. Charlotte Bronté and her sister Emily, in February, 1842, went to Brussels, in order, by acquiring a better knowledge of the French language than they already possessed, to qualify themselves for keeping a school. On the 30th of November, 1842, Emily returned to Haworth. Emily Bronté remained at home, but Charlotte returned to Brussels in the beginning of 1843. She was engaged as teacher of English in a school for young ladies, completed her education in French, made considerable pro-
gress in German, and returned to Haworth at the end of
February, 1843. The novel entitled "Jane Eyre," by Currer Bell, pub-
lished in 1847, was the first production of Miss Bronté's pen
which caught public attention, but it was not her first venture
in authorship. Her first essay was in a little volume of poems
"By Currer, Ellis, and Acton Bell," published in 1846. The poems
passed almost unnoticed, but the success of the novel was
immediate and extraordinary; and curiosity was for
some time exercised not only as to its authorship, but as to the
name of the poet, the many separate letters of which were
bearing manifestly the traces of a woman's mind, yet the
general cast of thought, it was urged on many sides, was as
evidently feminine. The appearance almost simultaneously of
the same peculiarities of thought and general style, with the names of Acton Bell and Ellis Bell were their authors, served to stimulate still further the public curiosity, and when it was confidentially announced that Currer Bell was the daughter of a clergyman in a remote part of Yorkshire, and that Acton and Ellis Bell were her
sisters, there was a general feeling of surprise almost amounting
to incredulity. In truth, "Jane Eyre" is a remarkable work, and as the production of the daughter of a country clergyman, it was to be still more remarkable if it were as unnecessary as it sometimes appeared to be composed, to provide acquaintance with society to obtain intimate knowledge of the human
heart, and to portray diversities of character. "Jane Eyre" was
followed in 1849 by "Shirley," and that in 1853, by "Villette," both marked by the same vigour of intellect, and keen, in fact morbidly keen dissection, of character and motives, though with less of that somewhat wayward originality which had in her first work called forth so much adverse criticism, but at the same time had excited such intense interest.
What is unpleasant, painful, morbid in these powerful
novels may, there can be little doubt, be set down to the action
of disease upon an overwrought and intensely susceptible mind. It came to an end at Haworth, on the 18th of December,
1849, of diseases which she had survived for years. The
director of the three gifted sisters, and in fact of all her father's
children. Emily Bronté (Ellis Bell), the author of "Wuthering Heights," and next to Charlotte the most gifted of the
sisters, died Dec. 19, 1849. Anne Bronté (Acton Bell), the author of "Agnes Grey," died May 28, 1849. Miss Bronté
married in June, 1854, the Rev. Arthur Bell Nicholls, her
father's curate; but pulmonary disease, the same insidious
malady which had carried off her sisters, had already marked her as its victim. She died at the parsonage, across the street
where her parents had lived, and where one of her sisters, in the
crowded but quiet churchyard there. In 1857 appeared "The
Professor, a Tale by Currer Bell," a novel written in 1848, but
left aside and much of it recast to form "Jane Eyre." The
whole of Currer Bell's works, 8vo. 1867, have been published
by Mrs. Gaskell. BRÖSS.EA, a genus of plants, belonging to the natural
group Ariceae. The fruit of B. cocciinea, like that of Gaul-
theria procumbens and Arctostaphylos alpina, is succulent and
covered with numerous seeds. BROWN, CAPT. SIR SAMUEL, R.N., was
born in London in 1776. At the age of eighteen he entered the
navy, and served with distinction during the French war.
He passed through the successive grades in his profession,
rising to the rank of commander in 1811, and accepting that
of retired captain in 1842. It is however as a civil engineer that Sir Samuel Brown has claim to remembrance. To his ability and longevity may
be attributed the marked distinction into which the whole system of
suspension-bridges. The idea of substituting iron cables in the
place of those made from hemp, first occurred to M. de Bougainville, whose account of a voyage which he made round the world was published in 1771. [Broussais, Louis, 1814-1888, French physician, who was the first to introduce the use of chloroform as an anesthetic. Although a patent was taken out by a Mr. Slater, a surgeon in the British army, in 1808, little was done until Captain Brown carried out a series of experiments, the results of which led to the introduction of the suspension-bridges. They were generally regarded as insecure, except for crossing narrow
streams, until Brown introduced his improved method of con-
structing chains for suspending the roadway. Instead of
chains of the ordinary construction, he proposed to form
them of long bars of flat or round iron, pinned together by
short links and bolt-pins. He made a model of his invention
in 1813, having however designed and prepared specifi-
cations for suspension-bridges much earlier, but he did not
obtain his patent till 1817. Brown's plan was soon after
adopted in principle by Telford (who had been in the first instance
proposed to use cables of merely the ordinary construction) in the
erection of his magnificent bridge over the Menai Strait.
The first extensive bridge erected wholly on Captain Brown's principles was at Berwick, in which the length of the chord-line between the
points of suspension is 449 feet; it was opened for use in
July 1829. In 1831 Captain Brown commenced the con-
struction of Trinity suspension-bridge at Newmarket, near
Edinburgh. He subsequently erected several other bridges and
pier, but it may suffice to mention, as his great work, the
suspension-pier at Brighton, which consists of four open-
ing of 25 feet each, with a deflection of 18 feet. The
Brighton pier has suffered considerable damage on two occa-
Sions in severe storms, but, as subsequently strengthened, it
has successfully withstood others of excessive force.
Captain Brown was knighted in 1833. He died on the
14th of March 1852.
BRUNEL, SIR MARK ISAMBARD, was born on April 25, 1769, at Hackney, in the department of L'Eure, a few
miles from Rouen. His parents, who were respectable agri-
culturists, had found opportunities for himself and his eldest
brother by a show of a decision for mechanical pursuits; and on being sent to the seminary of St. Nicaise at Rouen, preferred the study of exact science, mathematics, mechanics, and navigation, to the classics; and during his course of study, in which he now and
then derived some satisfaction, but was more often than not happier than when busying himself in a joiner's workshop.
He familiarised himself with the tools and some of their applications, and when but twelve years old was already
proficient in turning and in the construction of musical
instruments. All this constructiveness was little gratifying to his father, who would have preferred to see his son in the church or in the merchant's office.
On leaving the seminary at the age of fifteen, Brunel passed some time in the family of M. Carpenter, a friend of his father, at Rouen; and went through a regular course of instruction at the Pont-a-Mousson-bridge, with a view to the practice of his profession. He showed such interest in the astronomical part of his practical studies, that on his visits home he set himself to observe the stars, greatly to the astonishment of the villagers. He made an accurate map, guided only by the magnetic needle, and constructed a simple instrument of observation and a telescope; found, in its results unsatisfactory, he studied the instrument, and constructed another of ebony, which enabled him to take trustworthy observations.

He commenced perhaps by M. Carpenter, who had been a trading captain, Brunel enlisted as a sailor in 1796, from which date up to 1798 he made several voyages to the West Indies. He was remarked for the skill, intelligence, and good humour with which he discharged a seaman's duties; won the esteem of his comrades, and gained the respect of his masters by using by instruments of his own construction, and by making a pianoforte while the ship once lay at Guadaloupe. During a visit to Paris after his last voyage in 1798, Brunel ventured to raise his voice in one of the political clubs against the ferocious doctrines there actively promulgated, and thereby endangered his personal liberty; but, obtaining permission from the minister of marine, he escaped to America, hoping to find employment for his abilities in a new country.

Brunel settled in New York. Here he joined a party of his countrymen who were about to explore the wild and unsettled regions bordering on Lake Ontario, to survey the lands of a French company. The operations were carried on for two months, during which the party, seven persons in all, Brunel and his friends, accomplished their object. Their success was due to the fertility of their resource and to the care they took to follow all the indications of nature. With this, in which his fertility of invention and readiness in overcoming difficulties were strikingly manifested, his career as an engineer may be said to have begun. When designs for the houses of Congress were called for he sent one in which, though not the first in the line of design, was distanced by none and magnificent for simple republicans. He afterwards acted professionally as an architect, and among other works built and fitted up one of the principal theatres of New York. It has since been burned down. He was employed on the forts erected for the defence of the city, and in the establishment of an arsenal and foundry, where his ingenious contrivances for boring cannon and moving large masses of metal with facility, showed how successfully he could bring new ideas to bear.

In the family of his friend Carpenter, at Rouen, Brunel had become acquainted with Miss Sophia Kingdom. This acquaintance, and a desire to work among the scientific engineers of Europe, drew him to England. He made his mark in the Carpenters' Company, and the career of this country, produced an autographic machine, designed to copy drawings, maps, and written documents. Soon afterwards, he submitted to government a plan for making block-pulleys for ships by machinery, and was employed to carry it into execution in the dockyard at Portsmouth. The ingenuity of this contrivance is not less remarkable than the accuracy and economy with which its operations are performed. It comprises, so to speak, sixteen different machines, all driven by the steam-power; seven of which cut and shape logs of elm or ash into the shells of blocks of any required size, while nine fashion stems of lignum-vitae into pulleys or sheaves, and form the iron pin, which being inserted, the block is complete. Four men with this machine turn out as many blocks as four-score did formerly, and at less cost. The supply has never failed, even in time of war, though 1500 blocks are required in the rigging of a single ship of the line. It suits so satisfactorily produced a corresponding liberality on the part of government; and the inventor was rewarded beyond his expectation. The steam saw-mill in Chatham dockyard was erected by Brunel. The success of the circular saws there introduced led him to further improvements, by which the production of 1000 of these machines per year could be obtained. He invented a machine for making seamless shoes for the army, which, after two years' trial, was given up from an economical motive. Among other inventions may be enumerated a machine for making wooden boxes; for nail-making; to twist, measure, and form sewing cotton into hanks; for ruling paper; a contrivance for cutting and shuffling cards without the aid of fingers, produced in reply to a flattering request of Lady Spenser's; a hydraulic packing-press; new methods and combinations for suspending the engines of warships without centring. He was employed in the construction of the first Ramesgate steamer, and was the first to suggest the advantages of steam-tugs to the Admiralty. He constructed a carrying-cannon, acid gas as a motive power, and, assisted by his son, carried out experiments, for more than ten years, in the endeavour to bring it to perfection. Most of the mechanical difficulties were overcome; but although an intense power was obtained, and with a very slight increase of pressure, the cost of the water, as compared with the cost of the vapour of water, did not appear to be such as to compensate for the increased cost of the machinery, and the usual difficulties in its use.

Brunel's works of engineering construction are to be found in different parts of the country; but in the county in which he is most popularly known is the Thames Tunnel. This great work, commenced in March, 1825, was successfully accomplished, notwithstanding the accidents, obstacles, and overwhelming disasters that heaped its progress. The water broke in more than once, and flooded the whole of the excavations. Brunel, however, proved himself equal to each emergency, and his persevering genius at length triumphed. The tunnel was opened to the public in March, 1843.

In June, 1844, Brunel was made a Fellow of the Royal Society in 1814, and was chosen on the council, and appointed vice-president in 1833-33. He was a member also of other scientific societies and institutions. The honour of knighthood was conferred on him in 1850. With advancing years he became subject to a disease of which he had felt the first symptoms while completing the tunnel, and he died in December, 1849, having nearly reached the venerable age of eighty-one. His life is an example of what may be accomplished by genius, seconded by industry. The high character of his inventions, their essential usefulness, give them especial claims to consideration. In the words of a French writer, these have gained for him 'the celebrity that now distinguishes his name, the admiration of men of learning and of labour, and the affection of a nation.' Should he be enough to know him personally, could appreciate his simple and noble character.

(Traverses de l'Academie de Rouen; Proceedings of the Royal Society; Proceedings of the Institution of Civil Engineers; Quarterly Review.)

BRUSA. [Besa.]

BRYDGEs, SIR SAMUEL EGERTON, Bart., was born November 30, 1794, at Wootton Court, Kent. His father was Edward Brydges, Bart., one of the Knight of the Shire, and the daughter and co-heiress of the Rev. W. Egerton, LL.D., Prebendary of Canterbury, &c. Young Brydges was educated first at Maldon Grammar School, and afterwards at the King's School at Canterbury, and at King's College, Cambridge, entering at Queen's College in October, 1783. He left the University without taking a degree; entered himself of the Middle Temple in 1783, and in 1787 was called to the bar. He never practised, however; but having married in 1786, devoted himself to literature, and especially to genealogical and bibliographical studies. His earliest appearance in print was as a poet, a volume of 'Sonnets and other Poems' being published by him in 1785. Soon after the death of the last Duke of Chandos, in 1786, his uncontrolled imagination, excited perhaps by his somewhat superficial genealogical inquiries, a large share of vanity, and a passion for titles, led him to stimulate his elder brother the Rev. E. T. Brydges, to prefer a claim to the barony of Chandos, alleging that his descent from the first Brydges or Bridges, who bore the title. Litigation was protracted till June 1803, when the House of Lords decided that the petitioner had not made out his right to the title. Henceforward every thing which Sir Egerton Brydges wrote, was more or less a war for the lost dignity, and after the death of his brother, he always wrote himself 'per legem Terrae Baron Chandos.' The worthlessness of his claim is amply shown in a Review of the Chandos Peerage Case, adjudicated in 1803, and of the pre- Tregear and later editions. Since the latter the barony per legem Terrae Baron Chandos of Sadeley. By George F. Belas., Esq., Lancaster Herald, '8vo, 1834. By impoverished expenditure in the purchase and improvement of the estate of Denton, Kent, Mr. Brydges had early become involved in his pecuniary circumstances, and in 1810 he removed to London and acquired a small property in the Priory, the seat of his son, where he amused himself by set-
ting up a private press, and superintending the printing of various pieces in prose and verse of his own writing, and reading books. After countless efforts to get into parliament, he was elected in 1811 for Maidstone, which place he represented till 1818. In 1814 he obtained a patent of baronetcy. On losing his seat in parliament he retired to the Continent, where he remained till the fall of Napoleon at Compiègne Gros Joan, near Geneva, September 6, 1817.

Besides the works above enumerated, and several pamphlets on population, wealth, &c., Sir Egerton Brydges wrote 'The Topographer,' 4 vols. 1798-1800 (in which he tried to answer the objections of Mrs. Mary de Clifford, '1799'); 'Fitz Albini,' a kind of fictitious autobiography ('1798); 'Le Forester' ('1802); 'Comoingsby' ('1819); and 'The Hall of Hellingsea' ('1821). 'The Censusaria Literaria, a bibliographical work of some value, in 3 vols. 1807-1809; 'The British Bibliographer,' written in conjunction with Joseph Harswood, 4 vols. 1810-12; 'Resitits, or Titles, Extracts, and Characters in Old Books revived,' 4 vols. 1814-16; a new edition of 'Collins's Peerage,' 9 vols. 1812; 'The Ruminator,' and 'The Wanderer,' two series of essays, 1813, 1814; 'Occasional Poems,' 1814; 'Bertrand, a Poem,' 1815; 'Excerpta Tudoriana, or extracts from Elizabethan Literature,' 2 vols. 1819; 'Res Literarum,' 3 vols. 1820-21; 'Letters from the Lord Chief Justice to the Rev. Dr. Borys,' 1822; 'Gnomica, or Detached Thoughts;' 'Odo, Count of Liungen, a Poem;' 'Theatrum Poetarum,' 1824; 'Recollections of Foreign Travel,' 1824; 'The Lake of Geneva,' 3 vols. 1828; 'Imaginary Biography,' 3 vols.; and 'The Author of the 'Waverley' Novels.'

BRYDON, [Chemistry, S. I.]

BRYZA, a name proposed by Ehrenberg for those Zoophytes in which a higher organization is indicated by the presence of separate orifices for the mouth and anus. The same naturalist has applied the term Anthozoa to those Polyzoa in which the mouth and vent have but one orifice. These two classes of Polyzoa have been observed by Mr. J. V. Thompson previously to the publication of Ehrenberg's name, hence his designation for this family, Polyzoa, is more generally received. Other names have been given to this interesting family of Zoophytes. Professor Owen calls them Molluscan Zoophytes, on account of their structure being supposed to ally them to the Mol-lusca. For the same reason they have also been called Ascidioid Polyzoa (P. Ascidioidea). Milne-Edwards has also suggested Polytrocha, as the base of the fundamental order. Dr. Farre in a paper in the 'Philosophical Transactions,' 1837, proposes to call them Clyobrachia, in reference to the ciliated character of their tentacles. Mr. Busk in his Catalogue of the Zoophytes in the Collection of the British Museum, gives the component of the order Polyzoa as prior to that of any other. [POLYTOZA.]

BUCH, LEOPOLD VON, a distinguished geologist, was born on the 23th April, 1774, at Stolpe, in the Uckermark (Brandenburg). He came of an ancient and noble family, which reckons among its members not a few authors and statesmen. After the usual course of education, he became a student in the Prussian department of mines, and was marked for the earnestness of his scientific pursuits. In 1790 he entered the Mining Academy at Freiberg, where he had Humboldt for a companion, and where Werner, its eminent founder, taught the then novel science of mineralogy, in a way so interesting and genial, as thoroughly to enerve the spirit of the old pupils. Under his teaching grew up a school of young philosophers, destined to wield and confirm his reputation, and amend his errors, among whom Von Buch was one of the most conspicuous. In 1792 the publication of his 'Mineralogical Description of the Carlsbad region,' formed the first of that series of valuable papers with which he enriched his favourite science for the rest of his life—all distinguished as much by conscientious inference, as by perfection of observation. Next appeared his 'Systematischer geologischer Beschreibung von Landeck,' describing a little-known part of the geology of Schlesien, with (for that time) a very advanced geological map of the country. These works are followed shortly afterwards by 'Versuch einer geognostischen Beschreibung von Schlesien,' with (for that time) a very advanced geological map of the country. These works and many others were read in the meetings of the Neptunian theory prevailed; and it is no small proof of the accuracy of the observed facts that they are now easy to be reconciled with the present more enlightened theory.

In February Von Buch and Humboldt met in Styria, and spent some time in geographical excursions among the Alps, and passed the winter together in Salzburg in observation and verification of natural phenomena. In the following year Von Buch travelled alone, on foot, to Italy, and finished a topographical description of the countries he traversed, in which, besides the clearness of perception, there began to appear doubts as to whether the Wernerian doctrine was tenable in its integrity. He grew more and more doubtful of the correctness of Humboldt's conclusions. A friend Von Moll, he says: 'Make the finest and surest observations, and then go a few miles farther on, and you will find occasion, upon grounds just as certain, to maintain the very opposite of your former conclusions.' In February Von Buch arrived at Naples, and taking himself to the study of Vesuvius, described the phenomena in that picturesque and eloquent style which among other qualities characterized his writings. In 1802 he visited the volcanic region of Avignon. He revisited Italy, and was present at the eruption of Vesuvius in 1806. The results of these five years of observation were published in two volumes 'Geognostischen Beobachtungen auf Reisen durch Deutschland und Italien,' 1806-9, in which, among other subjects, he estimated the probability of the eruption of the Etna, the fact of the slow and continuous upheaval of the Swedish coast above the sea-level; and he made valuable observations in climatology and the geography of plants, as may be seen in his narrative 'Reise durch Norwegen und Lapp-land,' 1810: of which two volumes the second was published with notes by Professor Jameson in 1813.

The more interesting attach to these journeys as they were performed on foot. Few who met Von Buch walking with a hammer and a note-book, in summer a great coat with numerous pockets to contain maps, specimens, his hammer and note-book, would have believed that they beheld one whom Humboldt describes as 'the greatest geologist of our age; the first to recognize the intimate connection of volcanic phenomena and their mutual interdependence in regard to their effects and relations in space.' Possessed of sufficient means, Von Buch could gratify his inclination for travel, and for the encourage-ment of younger geologists, especially youthful students, less fortunate than himself.

In 1815 he sailed from England (accompanied by the Norwegian botanist Christian Smith, who afterwards met with an untimely death in Tuckey's expedition to the Congo), and in 1816 visited the southern coast of Africa. On his return from the Canaries, and in 1825 he published 'Physikalische Beschreibung der Canarischen Inseln,' with an atlas, of which the subsequent works, 'Über den Zusammenhang der basaltischen Inseln und Ueber Erhebungs-Krater,' and 'Über die Natur der vulkanischen Erscheinungen auf den Canarischen Inseln und ihre Verbindung mit andern Vulkannen der Erdoberfläche' may be regarded as supplementary. These volcanic researches alone would suffice to establish his reputation. The science of volcanology,—the fruitful source of many later advances—is therein developed and placed on a sure basis. He shows how the phenomena of upheavals are traceable to craters of elevation, and demonstrates the action of fire; and states his conviction that 'the ancient seas have not rolled away over the mountain chains, but that the mountain chains have been upheaved into the atmosphere, bursting through the series of strata in long lines—fissures—and that these upheavals have taken place at different geological epochs.'

Von Buch's life is strikingly manifest by his labours. His papers in the 'Abhandlungen' of the Berlin Academy of Science, would alone form several large volumes. They exhibit the development of his scientific views from first to last. His activity is also evident in his ideas in his paper 'Über das Fortschreiten der Bildungen in der Natur,' as to the progress of forms in nature, and when past the age of
fifty, he showed how the ideas had ripened in his mind by his papers on the Ammonites, Cyphites, Torosporites, Ortho, Pro-
dacta, and others, accomplishing for the geologist what Cuvier had accomplished for the physi-
ological branch. In the words of the late Edward Forbes, it was Von Buch "who first developed the idea of the chronomor-
phology of genera, the greatest leading principle of natural history applied to geology." He is also noted for moving on to a new field of study, in which the important conclusions which he shows to be deducible from the nervation of the leaves of fossil
plants. And in his writings on climate, on hail, the temperature of springs, and the geography of plants—guiding princi-
ple of his life—he always—no, he proves himself an able physicist as well as geologist.

In his many journeys Von Buch visited Sweden and Nor-
way, and Avenger a second time, and any excuse sufficed to
draw him to Switzerland. He would leave his house in Berlin without telling any one of his intentions, remain away for weeks or months, and return as unexpectedly. He liked to find out and make the acquaintance of geologists of emi-
nence, and for this purpose he attended the meetings of naturalists on the continent and of the British Association
in England. He was present at the Werner festival, celebrated
with so much pomp at Freiberg, in 1860. He never married,
was somewhat eccentric in his habits, but always serious
as regards science. When asked for his titles he was accus-
tion that the Royal Prussian Student of Mines branch of
created a baron, a knight of the Order of Merit (Berlin),
and of the Red Eagle, and held the appointment of royal
chamberlain in the court of Prussia. He was a member of
the Academy of Sciences of Berlin, and of the chief scientific
societies of the world. His many failures in black cloth, for a ship
was elected a foreign member of the Royal Society of London,
and in 1840 was chosen one of the eight foreign associates of
the French Academy of Sciences. He died at Berlin, after a
few days' illness, on the 4th of March, 1839.

"Von Buch was a genius," says E. Forbes, in his anniver-
sary address to the Geological Society. "He went about the
world casting the seeds of new researches and fresh ideas,
wherever his prophetic spirit perceived a soil adapted for
these plants. ... Yet he is the only geologist who has attained
an equal fame in the physical, descriptive, and natural
history departments of science. In all these he has been an
originalist and a discoverer. In every subdivision of
all three he has been a suggestion—a high merit in itself."

The "Abhandlungen" of the Berlin Academy of Sciences,
Leonhard's "Taschenbuch for Mineraloge," and other German
scientific periodicals, contain most of Von Buch's papers.
Among his other scientific records is the section on the "Umbold in America"—"Die Blumen insel, geographisch
beschrieben," 4to, 1847; "Ueber Carilibonu besonders von
denen die in Kreidebildungen sich finden," 8vo; besides
those above-mentioned. A French translation of his "Canary
Island excursion," published at Paris in 1836.

BUCHOLZITE, a mineral closely allied to Sillimanite.

According to Thompson it is composed of—

Silica 484
Alumina 529

A specimen from Chester, Pennsylvania, gave Erdmann—

Silica 401
Alumina 120
Paroxid of Manganese (a trace)

It is found at Fassa, in the Tyrol, and in several districts in the
United States.

BUCKIDA, a genus of plants belonging to the natural order
Cembracae. One of the species, B. Buxara, yields a bark which
is used in tanning.

BUCK. [Dexa.]

BUCKINGHAM, JAMES SILEM, was born in 1756, in
the marine village of Flossing, near Falmouth, in Cornwall.
His father was a farmer, and died while Buckingham was yet a boy. His
father sent him to school at Falmouth, and was desirous of
bending him up to the church, but he preferred going to sea, and
made a few voyages to Lisbon, in the last of which his ship
was taken by the French, and he was made prisoner.

After some delay they were set at liberty, but his
way home were impresssed for the British navy. Buck-
ingham however escaped from the press-gang, returned to
Cornwall, and entered into an engagement with a bookseller
at Devonport, in whose employ he remained about four
years; and here he seems to have gained some knowledge of
the trade of a printer. He however took to the sea again on
board a king's ship, but deserted, returned home, treated the
law, and abandoned that profession also. He married before
he was twenty years of age. About this time his mother
died, leaving him a considerable property in charge of true
trustees. He was entered business as a bookseller, on bor-
rrowed money. One of his trustees, however, finding his
business proved a failure, and he was left destitute with a
wife and female child.

Leaving his wife in the care of her friends, Buckingham
then went into the West-Indian trade, and was appointed com-
mandant as captain of some vessel; but having waited till his
bark was almost in a state of starvation, he obtained employment
in a printing-office, and was afterwards engaged at the Clarendon
press, Oxford. At length he was appointed captain of a
West-Indianman, and continued four or five years in the
trade. He afterwards was a captain in the Mediterranean
trade, and made many friends at Malta and Smyrna. He
then resolved to settle at Malta as a ship-owner and mer-
chant, and having purchased a cargo of goods, he sailed from
London in April 1813. When the vessel reached Malta, the
plague had broken out there, and no persons were allowed to
land; the cargo however was taken on shore, and the ship
then proceeded to Smyrna. While he remained at Smyrna,
he bought a ship and took goods in Alexandria, and he and others lost
all his property.

Buckingham then resolved to try his fortunes in Egypt,
and left Smyrna for that purpose, August 30, 1813. He
was well received at the British Embassy, and was introduced
to several of the leading Bactrians, of whom he was especial-
ly the pasha, Mohammed Ali, who was then absent on an expedition
in Arabia. At this time there was much speculation about
returning the commerce with India through the Red Sea, and
Buckingham was making a new voyage to the Mediterranean.
Buckingham had a despatch forwarded to the pasha, in which
he offered his services to examine the Isthmus of Suez for an
eligeable track, and to trace as far as possible the course of the
ancient canal. His offer, after some delay, was accepted,
and he was enabled to return to Cairo, and having arrived
at the cataracts, he started from Kneze on the Nile, with a
single attendant, for the purpose of travelling to Kosseris on
the Red Sea. His attendant deserted him on the route, he was robbed
of everything he possessed, and was left entirely naked.
He was befriended by a poor Arab, who supplied him with some
scanty covering, and at length reached Kosseris, whence he
was obliged to return to Kneze, and thence to Cairo,
without effecting anything. At Cairo he was introduced to
the pasha, who appointed him as his representative for inter-
ventions, and for the purpose of conducting the trade of the
ships for him in India, and to encourage a trade between
India and Egypt.

Mr. Buckingham then left Cairo for the purpose of
proceeding to Bombay by the Red Sea, and reached Suez, October
18, 1814, and Bombay April 6, 1815, having been delayed in
Arabia. He found the merchants at Bombay distrustful of
the pasha of Egypt, and unwilling to trade with him; he
therefore accepted an engagement from the agent of the
Imam of Muscat as commander of a vessel for the return to
England, which was intended to trade to China on the Imam's
account. When this was made known to the civil authorities
at Bombay, and also that he had no licence from the East
India Directors to trade in India, he received an order to
return to England, but, after much remonstrance on his part,
was allowed to return to Egypt in one of the East India
Company's ships, which was about to proceed up the Red Sea
for surveying purposes. He accordingly sailed from Bombay
June 27, 1815, was landed at Suez, and reached Cairo No-
ember 20, 1815. On his return to England he took many
parties to Alexandria, and was received with the utmost
honor, and at the time he was more or less understood
in all those countries.

From this period his proceedings in the East are imper-
fectly known. In 1816 he was in Calcutta, and established
a journal there, but the boldness of his censure of the mal-
administration of Indian affairs led to his expulsion from the
presidency of Bengal; his printing-presses were seized, and he was compelled to return to England.

Dr. Buckland, Mr. Buckingham delivered many lectures against the monopoly of the East India Company, and in support of opening the trade to China. A liberal subscription was entered into to reimburse him for the losses he had sustained by the suppression of his journal. He published an original work on "The Professor," which became the precursor of several similar journals, and "The Athenæum," which is now the leading literary journal among those which are published weekly. In 1822 he published his "Travels in the East and West Indies," in 1823 "On the Natural History of the Brontosaurus," in 1827 "Travels in Mesopotamia," in 1830 "Travels in Assyria and Media." At a later period he made several tours through various parts of Europe and of North America. He published 8 vols. on Belgium, the Rhine, and Switzerland: and 3 vols. on England, Scotland, and Ireland. He passed nearly three years in America, and traversed the United States in all directions, from Maine to Louisiana. His "Travels in America" comprise:--3 vols. on the Northern States; 3 vols. on the Slave States; 3 vols. on the Eastern and Western States; and 1 vol. on Canada, Nova Scotia, and New Brunswick. Much of these volumes however consists of statistics, and a great variety of other matters of compilation. Their literary or other worth is very small.

Dr. Buckland was a supporter of the liberal members of parliament for Sheffield, and he retained his seat till 1837. He was a supporter of liberal policy, and especially of social reforms. For many years his chief occupation was the delivery of public lectures in various parts of the country. His subjects were generally of a high tone, and his manner was always popular and pleasing, and his lectures were always fully attended. In 1843 he was the chief agent in establishing a literary club called the British and Foreign Institute, of which he was appointed secretary, but which ceased to exist in about three years. In 1849 he published "National Evils and Practical Remedies," 1 vol., in which he expounded his views on many subjects connected with the public welfare. He was a zealous advocate of the temperance movement, and he was elected a member of the Temperance Union in 1851. In 1855 he published the first two volumes of his "Autobiography," and he intended to publish the next two volumes in the course of the same year, but he closed his life of extraordinary vicissitudes and adventure on June 26, 1855. The court of directors of the East India Company had made amendments for their former ill-treatment by granting him a pension, which he enjoyed for a few of the last years of his life, and which is continued, we believe, to his widow, with a moiety of his house, which had been his seat, and had also for a few years a pension of 200l. a year from the civil list. The manuscript journals of his various travels occupy, as he states in his "Autobiography," 28folio volumes, chiefly according to the Geological Museum at Oxford owes its chief excellence to Dr. Buckland's industry in procuring and arranging specimens, particularly of the remains of the larger Fossil Mammals, and other animals from the caves in different parts of England and Germany. He spared neither pains nor expense in travelling to make the collection worthy of the university and the science it was intended to illustrate, as exemplified in his "Descriptive Notes," with sections of 50 miles of the Irish coast, made conjointly with the Rev. W. C. Forster, in 1833, near Lindaff, during a tour in Ireland in 1813, and published in the third volume of the "Transactions of the Geological Society." In 1818 Dr. Buckland was elected a Fellow of the Royal Society. In 1830 he delivered a lecture before the university of Oxford on a title of the "Catechismus Geologicus," or the Connexion of Geology with Religion explained. The object of the lecture was to show that the study of geology has a tendency to confirm the evidences of natural religion, and that the facts developed by it are consistent with the accounts of the Creation and Deluge as recorded in the Mosaic writings.

In 1829 he communicated to the Royal Society an "Account of an assemblage of Fossil Teeth and Bones of elephant, rhinoceros, hippopotamus, bear, tiger, hyena, and sixteen other animals," which was a cave containing a bear's den, the whole of which in the same year the society awarded him their highest honour, the Copley medal. This paper was made the foundation of a treatise published in 1835 "Reliquiae Diluvianae, or the remains of the Deluge," a work the title of which he gave to the "Action of a Universal Deluge," which proved of essential service in the promotion of geological science.

In 1825 Dr. Buckland was made canon of Christ Church, Oxford. He was president of the British Association at Oxford, and in 1826 he published his Bridgewater Treatise, "Geology and Mineralogy considered with reference to Natural Theology," 2 vols. 8vo. The discovery of new facts had materially advanced geological science, and improving in this work the erroneous diluvial theory, Dr. Buckland brought the weight of his authority to support the views now generally received. One of the most able of his numerous geological writings, as subsequently testified by Murchison and Sedgwick, was a sketch of the "Transitional Species," 1820, "Annals of Palaeontology," in which he showed, for the first time, that many crystalline rocks of this chain are of no higher antiquity than our Lias, Oolitic, and Cretaceous formations.

The "Transactions of the Geological Society" contain his "Geological Observations," 1825, which formed a part of Dr. Buckland's skill as a field geologist, as well as a paleontologist, and among them, his description of the south-western coal district of England (1825) may be mentioned as an example. It has stood the test of more than thirty years, and is still appealed to as a standard work.

Dr. Buckland was chosen on the council of the Royal Society in 1827, and in subsequent years up to 1849. He was one of the earliest fellows of the Geological Society, and was the only one of his title who has been president of the society. His early obituary addresses are printed in the society's "Journal." He was also a Fellow of the Linnean Society. In 1845 he was made Dean of Westminster; and, coming to reside in London, he was appointed a Trustee of the British Museum in 1847, and took an active part in the meetings of scientific societies, and in the establishment of the Museum of Practical Geology in Jermy-street. In the year 1850 he was obliged, in consequence of disease of the brain, to resign the Deanery, and he died at Chiswick on the 14th of August 1856.

BUFFALO, AMERICAN. [Bosu.] Bugeaud de la Piconnerie, Thomas Robert, Duc d'Isly, Marshal of France, was born at Limoges, 1784. He belonged to a good family, most of the members of which were among the emigrants of the first revolution. Young Bugeaud, however remained in France, and having chosen a military life, entered the army as a private in 1804. At Austerlitz he distinguished himself; the following year he was made sub-lieutenant. He served in the campaign of Prussia and Poland, and was wounded at Pultsk, Nov. 26, 1806. Sent into Spain as adjutant-major he speedily caught the eye of Marshal Suchet, who in his despatches makes frequent mention of Bugeaud's merits. He in consequence rose steadily in professional rank till he was made lieutenant-colonel, and appointed to the command of the 14th regiment of the line. On his return to France he was created a marquis.

The abdication of Napoleon I., Bugeaud gave in his adhesion to the restored dynasty; but, with most of the other officers, went over to the emperor on his return from Elba. During the Hundred Days he had the command of a small body of troops, and with it he succeeded in defeating a much superior Austrian force at the Flandre-ouest-Confins, June 1816. Upon the second restoration, Bugeaud retired to his estate, where he diligently cultivated the soil, till the revolution of July 1830 called him again into public life. He was elected a deputy of the Rhone, and became an earnest supporter of Louis Philippe, whose confidence he quickly gained, and who made him marshal. In January, 1834, occurred a deplorable event, which caused the death of the Marshal. The Marshal was married to a Countess Dupont, and she had a son by him: this son was very much beloved by the Marshal, and was living in Paris, near the Opera; this son, however, had been a great spendthrift, and Bugeaud was becoming extremely popular: this was the death of M. Dulong, in a duel between him and General Bugeaud, arising out of some
in Ohio in America, which is in part a true sandstone, and contains fossils. It also contains lime, and Mr. Dana sug-
gests that the knowledge of the lime by solution may have
given it its cellular character. It is a very hard rock, a
formation, and has an open cellular structure where carved for
millstones. The quartz rock of Washington in the United
States is in some parts cellular, and makes good millstones.

Bulgaria is noted for its copper and lead is found near the Carolina line, and in
in Arkansas near the cove of Wichita. (Dana, Manual of
Mineralogy)

BULGARIA, a country of Turkey in Europe, is bounded N. by the Danube, which separates it from the principal-
ity of Servia and the Balkan; S. by the Black Sea; and E. by
the cessions of Eminish and Khojsh Balkan; and W. by the prin-
cipality of Servia, from which it is partially divided by
the Danube. The country is about 224,000 square miles, and the population according to the estimate of
1844 was about 3,000,000, the majority of whom are adherents of the Greek Church. The area is thus distributed,
as nearly as we can ascertain:—Par-halic of Silistra,
including the territory of 13,000 square miles; pashalic of Nicopoli, 10,000 square miles; pashalic of
Widdin, 4,600 square miles; and a portion of the pashalic of Sophia, 4,600 square miles. These divisions however do not
 coincide with the present Turkish divisions of Bulgaria, which is divided into several smaller Sultanates, or
Duchies, or Provinces, as the Bulgarians call them. We retain, however, the old divisions in our maps.

The Danube runs with many windings, but in the general
form of a bow, with the convex side towards Bulgaria, all
the tributaries of the Danube flow to the north of the
river, and on the western side till they join the river, and thence it turns to the eastward and enters the Black Sea
by several mouths. (Bessarabia; Danube.) Reckoning all
its windings the river flows along the province for not
less than 500 miles, and is navigable for steamers and large
vessels all the way. Its course is serpentine in form, with
islands on both sides; its current is from north to south,
but on both sides of the river at intervals are extensive
marshes, which in the dry season are very unhealthy and
infested by moccinites.

The Balkan mountains are also called the ancient Haemus, and the
southern frontier to about 6000 feet, but the higher
heights sink rapidly on the south side; on the north the slope is more
gradual. The chain is traversed by many defiles and passes.

[Balkan.] From its crest numerous ramifications extend
northward to the plain of the Danube. These defiles are
in general well wooded or covered with rich pasture;
and they are separated by valleys or small plains drained
by feeders of the Danube. The principal of these rivers,
commencing on the Servian frontier and proceeding eastward,
flows through the valleys of the Strymon and Vardar, and
cross the pashalic of Widdin; the Wid, the Oma, the
Jantro (which passes the town of Tarnova), and the Lom,
which traverses the pashalic of Nikopoli, sometimes called
Shermenu and Samerene, and the south and north
Jemuru, and the Kara-Su, which drain that part of the
pashalic of Silistra which belongs to the basin of the Danube.
The Kamitch, which rises west of the Selimo Pass of
the Balkan, flows eastward through a longitudinal valley
between parallel ranges of the Balkan, and enters the Black
Sea between Cape Emenish and the port of Varna. In
the mountains that screen the valley of the Kamitch on the
north is the town and fortress of Shumila. The most
important of the other tributaries of the Black Sea in Silistra is the
Parawadi, which passes through the marshy lakes of
Devno and falls into the port of Varna. The Parawadi River is
identified by General Jochmus in his 'Notes of a Journey to the
Balkan' with the ancient Lygino; and the site of
Alexander's battle with the Triballi (a.c. 332) he considers
the isthmus between the two lakes of Devno, a little
west of the village Bayuk-Aladin. Not far from the same
spot, but nearer Varna, is the site of the great battle fought
between the Sultan Murad and King Wladislaus in 1444.
The site is locally identified by two large mounds called
Sandalk Tepé and Murud Tepé.

The coast of Bulgaria, or Silistra, from Cape Emenish, the
eastern extremity of the Balkan, to Cape Kalakria or Guigrid
is about 180 miles. The route goes through the
mountains of the Vardar, turns north, and runs north
west; the coast south of this last point the shore is for the
most part flat, low, and marshy. The most important places along this coast are the
city, port, and fortress of Varna, and the little town and
roadstead of Kustenjieh, which is only about 30 miles distant
from the point where the Danube makes the great bend
in northward. It has been lately proposed to cut a navigable

Bulgaria is noted for its copper and lead is found near the Carolina line, and in

Mineralogy)
neighbourhood of Kustenjë is inhabited by Bulgarians, and a good number of Russian colonists from Bessarabia, who have secured the situation of the peasants by a higher quality. In the rest of Silistria the country is well cultivated throughout, and yields an abundant supply of provisions of all kinds. Hard wheat of two kinds, distinguished by the name of "black," is grown in great abundance. Barley also of fine quality is extensively grown.

The other crops are maize, beans, and hemp, which in years of drought do not succeed so well. Several thousand oxen are slaughtered in the city of Silistria for the tallow, which is exported in the form of tallow works.

The eastern part of the pashalik of Nicopoli is well wooded as far as the neighbourhood of Rastchuk; it also possesses abundant pastureland, and, in ordinary years, when not visited by long drouths, it is very productive in corn. Woodcutting is the chief occupation of its inhabitants, and the peasants of this part of the country are all freemen. Between Rastchuk and Sistova the plain of the Danube is occupied densely and solely by Bulgarians, and presents a fertile and pleasing aspect. Besides corn, the chief products are hemp, flax, salt, and corn, and tallow. Sistova is considered the capital of the Bulgarians; it is one of the most important towns on the right bank of the Danube, and carries on a considerable trade with Wallachia. Westward from Nicopoli, and throughout the greater part of the pashalik of Wallachia, the Danube is less navigable, and the farmers being met with only where there is water, and agricultural produce is raised merely sufficient for the local consumption.

The plain of the Danube here partakes of the nature of a steppe, and is covered with pasturage as far as the eye can reach. The cultivation of corn for export was long effectually checked in this part of Bulgaria by a restrictive system, by which the farmers could not sell their surplus produce without the pasha's permission, and at a price fixed by himself. Sometimes the pasha appropriated the surplus himself, ground it at his own mills, and then forwarded it for sale to Constantinople. These regulations have been very injurious to the trade of Widdin, which, however, has a considerable commerce in manufactured goods imported from Austria.

The tallow trade causes the rearing of large numbers of cattle in Bulgaria. Large herds of oxen, to the number of 40,000 or more, are fattened during the summer months, and slaughtered during the autumn, in the neighbourhood of Varma, Sistova, Rastchuk, and other towns, for their hides and fat; for beef is seldom eaten by the Moslems, whose favourite animal food is mutton and goat. There is a depot at Varma for the tallow and other products of the province. Goods are conveyed there by the Danube. The navigation, and vexatiousness of the Russian quarantine regulations, the corn and other products of Bulgaria are generally brought by land carriage to Varma for export even from the plain of the Danube. Corn, however, for export to Constantinople is conveyed by the Danube, and the Russian custom-houses cut off the trade. Besides, corn is sometimes exported in the form of flour, to the extent of 100 tons, which is frequently shipped from the port of Matin, a small port opposite Brailoff, and then embarked in larger vessels. From the roadstead of Kustenjë also large quantities of corn are occasionally exported. The export condition of this part of the harvest since the destruction of its mole (built by Constantine the Great) is a great obstacle to its trade. Its position, however, has been at all times considered of great importance, as it is only 30 miles distant from Cernavoda on the Danube. A canal was projected in 1837 to unite the two points, and to give a short and direct route to the Danube trade, by avoiding the great northern bend of that river, and the intricate shoals and mud-banks in its mouth. This project has been recently revived, and will probably be executed.

Besides horned cattle, including buffaloes, Bulgaria rears a great many horses of inferior breed, sheep and goats in great numbers, and swine for the consumption of the Christian part of the population; but, as a whole, it is a poor Jew, is an abomination. The manufactures of the country are all of a coarse description, and for home consumption. The imports are manufactured goods, coffee, spices, sugar, salt, &c.

The principal towns of Bulgaria are—Widdin, Nicopoli, Sistova, Rastchuk, Silistria, Rassowa, Tarnovca, Sophia, Varna, Kustenjë, Shumen, Niza, &c., of which the most important are described under their respective names.

Bulgaria comprised the greatest part of ancient Mausia, which was occupied in the time of the Persian, and in the time of Alexander by the Triball. It is a very in-
wasting country for its historical associations, to illustrate which there is great need of enlightened exploration. Ge-
nerally speaking, the somewhat stationary situation of Slavonic countries has thrown a faint light upon the history of the expansion of Darius and Alexander in this country. He supposes Darius to have crossed the Balkan by the north-west of Mes-
embria, and to have marched northward to Isatacha by the way of the river Rupesh. He gives the following as the opposite direction in the campaign of 328. Alexander, he says, fought the action with the Thracians at the foot of the delib of the Balkan to the north of Aides; thence crossed the delib to the Lygion, near the town of Parawadi; and, after his victory, marched thence to the mountain in three days to the Danube, which he is supposed to have crossed at or near Siliistra, for the purpose of attacking the Geta. Bulgaria contains some Roman remains: the great system of fortifications in the flat of the Danubine, and the healing of Dyrachium on the Adriatic crossed the valley of the Timok, the ancient Timicac, above Widdin, and is still in parts entire. On the road from Shumia to Rostschuk numerous ancient mounds, covered with forest trees, are passed at a place called Lazaret, marking no doubt the site of some great ancient battle.

Moesia was originally inhabited by a Scythic or Slavonic people. It was subjected by M. Licius Crassus about A.D. 26, the Romans, who built entrenched camps along the Danube near Rupesh, and near the town of Philippopolis. The 3rd century it was invaded by the Goths, whose incursions were not thoroughly checked till the time of Aurelian, who planted several Roman colonies in the province. It was again invaded by the Goths in 375, after the defeat and death of Valens at the great battle of Adrianople in a.d. 378, ceded the country; and a part of those who settled in the western part of it are known in history as the Mosse-Goths. In the 6th century Slavonic tribes spread over Lower Moesia, and in the 7th century Upper Moesia was given by Heraclius to the Serbs and other Slavonic people, to protect the empire in that direction against the Avars.

The Mesnja, a Tartar people from the banks of the Volga, subdued the Slaves of Lower Moesia about the middle of the 7th century; but became in a short time so blended with the Slavonic part of the population, that before the commencement of the 9th century they had adopted the Slavonic language and customs, the name of the race which gave its designation to the country alone remaining. They were governed by kings who put themselves under the protection of the Greek emperors. This alliance however they renounced in 1165, their king Asan remarking that the Greek emperors were in constant quarrel with Hungary. At the end of the 12th century, the Turks occupied Albania, and the country was delineated between this and the 13th century, when Bulgaria was subdued by Stephen IV. about the time that the Turks made their first appearance in the Balkans. Under the Emperors of Nemanich, under the Sungem princess, and the people lost their independen-

cence. There are many Bulgarian colonies in Thrace and in the countries along the left bank of the Lower Danube.

During the Russian war of 1853-4 a portion of Bulgaria was seized and occupied by the Russian troops, and the fortress of Siliistra was besieged by them, but was not taken.

BURRIS, MISS. [D'Arrail, Madame, S. 1.]

BURNET, Miss. [Sangussofa; Potterm, S. 1.]

BURNETT, Miss. [D'Arrail, Madame, S. 1.]

BURNISLAND, Fifeshire, Scotland, a town, royal burgh, and sea-port, in the parish of Burnisland, on the north or left side of the Firth of Forth, is situated 22° 44' N. lat., 3° 13' W. long., about 54 miles nearly due north from Leith. The population of the royal burgh in 1851 was 2329, of the parliamentary burgh 2724. The burgh is governed by two bailies and ten councilors, of whom one is provost and unites with Kirkaldy, Dysart, and Kinghorn, in returning one member to the Imperial Parliament. Burnisland was made a royal burgh in 1588. At the Great Seal of Scotland which rested here in 1504 James VI. took the oath to the Coronation. The town was formed in the reign of Charles I., and besieged and taken by Cromwell, who repaired and considerably improved the harbour. The town chiefly consists of two parallel streets terminated by the church. The harbour is deep and very commodious. Being now the principal ferry station, the town has much increased of late years. There is a good dry dock; and on the eastern pier is a lighthouse, the light of which may be seen a distance of seven miles. Burnisland formerly possessed a considerable trade. About 1862 there were twelve ports, including St. Andrews and the now extensive
port of Kirkaldy, which were subordinate to Berwick.

For many years past its traffic has been confined to that arising from the carking of herrings and from distilleries in the neighbourhood. Ship-building is carried on. There is daily steam communication with Granton on the opposite coast, and the Edinburgh and Northern railway opens up a direct communication with the whole north-east of Scotland, the passage across the Frith being effected here by a floating railway.

The parish church was built in 1592. There are also a Free church, and chapels for Episcopalians and United Presbyterians.

North from the town, on the summit of Dunesarn Hill, an eminence rising 695 feet above the sea, is a level space surrounded with a number of loose stones, which has been called Agricola's Camp, and supposed, very improbably, to mark the site of a Roman encampment. On another eminence overhanging the harbour stands Rossend Castle, erected about the 15th century.

Bute, one of the islands which compose the county of Bute, Scotland, is situated in the Frith of Clyde, between 56° 46' and 56° 06' N. lat., 4° 66' and 5° 10' W. long., distant about six miles from the opposite mainland of Ayrshire, and about half a mile from Arryleshire, from which county it is separated by a narrow and crooked but picturesque channel called the Kyles of Bute. The population of the island in 1851 was 10,661. The island is about 16 miles long, and varies from three miles to four miles in breadth. To the north it is elevated, rocky, and barren; the central part is diversified by hilles, valleys, and fertile tracts; and the south end is hilly and divided from the rest of the island by a low and sandy plain called Langal-chord. The coast is rocky and indented by bays. The soil of the island consists of clay, loam, and sand, with moss lying on gravel. The greater part of the arable land is inclosed and cultivated; barley, oats, potatoes, turnips, and the artificial grasses are all cultivated with success. About the middle of the island are three small lakes—Loch Fad, Loch Ascog, and Loch Quein. The climate though damp, is mild and temperate, and the island is much resorted to by invalids, Kethsay being one of the favourite watering-places of the Clyde. The minerals are limestone, freestone, slate, and some indifferent coal. Beds of coal and shales, of considerable thickness, are found in several places half a mile from the sea-coast.

Bute island contains many remains of antiquity. Dun-ghle, or Dungallag, a vitrified fort, attributed to the Danes or Norwegians, and situated on a lofty crag in the southwest part of the island, is an object of interest and curiosity. In the southern extremity of the island are the ruins of an ancient chapel. Not far from the ruins are the remains of a circular erection about 30 feet in diameter and 10 feet high, known as the 'Devil's Cauldron'; the object for which it was erected has not been ascertained. Bute, and the adjacent islands, were long subject to the Norwegians. Harco of Norway in 1883 took possession of Bute, but after his defeat it returned to the allegiance of the King of Scotland. Edward of England held it till 1312, when it fell into the possession of Bruce. Robert III. and James III. made the island their occasional residence. It was garrisoned by Cromwell, and was the scene of the Earl of Argyre's unfortunate landing in 1685.

(The New Statistical Account of Scotland.)

BUTE, a genus of birds belonging to the order Raptora and the family Falconidae. It includes, according to Yarrell, two British species, B. vulgaris, the Common Buzzard, and B. lapogus, the Rough-Legged Buzzard. [FALCONIDA.] Various other species of the Falconidae have been included under this generic name. [Yarrell, British Birds.]

BUTYRONE. [Chemistry, 52.]

BUTYRYLE. [Chemistry, 52.]

BYRONIMA, a genus of plants belonging to the natural order Malpighiaceae. The bark of the species is astringent, and is used extensively for tanning in the Brunia. The wood of some of the species, especially B. variaefolia, is of a bright red. The bark of B. eurysilis is used in fevers. B. casiasi is one of the thousand remedies for rattle snake bites. It is called Chapera Maneta. The Alconeroe Bark is the produce of B. laurosifolia, B. rhopalosifolia, and B. co- colocosifolia. The acid and astringent berries of B. eurysilis are said to be good in dysentery. [Lindley, Vegetable Kingdom.]

BYTOWN, Canada West, the chief town of Carleton County, is situated in a very beautiful part of the country on the Ottawa, near the junction of the Rideau Canal with that river, in 45° 20' N. lat., 75° 45' W. long.; distant 186 miles N.N.E. from Kingston, and 284 miles N.E. by E. from Toronto; the population of the town in 1851 was 7780. The lower town, which is the older part, is in which bu-iness is generally carried on: the upper town is of more recent erection; it is situated about half a mile distant on a more elevated site, and consists chiefly of private residences. Considerable improvement has taken place in the appearance of Bytown of late years. Several handsome stone buildings have been erected. The town contains places of worship for Episcopalians, Presbyterians, Wesleyan Methodists, Baptists, and Roman Catholics; several schools, a commercial reading-room, a mercantile library association, a court-house, barracks, and a jail. Bytown is supported chiefly by the lumber trade, a term applied to the system of floating large rafts of rough timber down the rivers of America to the depots and ports in the lower parts of their course. Timber cut on crownlands and brought down the Ottawa River is measured at Bytown, and the owner gives bond to pay the duties at Quebec. The value of timber brought down the river in one year, 1844, was estimated at 341,700L. About three-fifths of the whole being cut on crown-lands was liable to duty, amounting to about 24,000L. Pairs are held at Bytown in April and September. Steamers ply between Bytown and Grenville on the Ottawa, and between Bytown and Kingston on the Rideau Canal.
CACELOT. [WHALE.]

CACODYL. [CHEMISTRY, S. 1.]

CADDICE, CADDIS-WORM, or CAD-BAITE, the common name for the larvae of the species of Phryganea, which reside in the water, in cases which they form of various sub-
stances, such as bits of stick, grains of sand, and all stones, shells, &c., which are held together by a silken thread secreted in their bodies in the same manner as in the silk-worm. The case acts as a protection to the larva, and it is capable of drawing in its head or putting it out, according to the cir-
cumstances.

CALAMOPHILUS, a genus of Birds belonging to the family Parisidae and the tribe Incessores, sub-tribe Dendroctres. C. biannricus of Yarrell is the Porus biannricus of Pensaent and other writers. This bird is common in Great Britain, and is known by the name of the Bearded Tit. [TITCHEN. (Yarrell, British Birds.)

CALEDONIAN CANAL, a connected series of lakes and canals extending through Glenmore, or the Great Glen of Atholl, and connecting the Western Ocean with the North Sea. It runs through foreshore and customs estates occupied the celebrated James Watt to report on the practicability of a canal from sea to sea through Glenmore. Watt's report was not favourable; but the foreshore estates having been soon after restored to the families to which they had formerly belonged, the office of trustee was abolished, and the project dropped. In 1802 the scheme was revived, and government employed Mr. Thomas Telford, the civil engineer, to re-
survey the district, and to report on the result of his investiga-
tions. This report was in favor of the construction of the canal, and the work was instantly proceeded with under Mr. Telford's direction. Operations were commenced in 1803.

In 1803 the eastern division of the canal was opened for navigation, and in 1822 the whole canal was opened for navigation. The toll on the passage was opened accordingly.

The Caledonian Canal commences on the south-west on the shore of Loch Eil at Carphag near Fort William, in 56° 56' N. lat., 5° 12' W. long., and joins Loch Lochy by a cutting 8 miles in length; a short cutting of about 3 miles between the Loch Louchy and Loch Oich; a canal nearly 6 miles long continues the navigation from Loch Oich to Loch Ness on the north-west end of Loch Ness a canal of about 7 miles in length also continues the passage to Crichton near Inverness; whereas another short artificial cutting, it opens into Monadh Frith on the shore of Loch Beauly, in 57° 56' N. lat., 4° 15' W. long. The length of this communi-
cation between the west and east seas is in all about 60 miles, of which rather more than 37 miles are through natural sea, and his life was devoted to improving them by the aid of cutting. The summit level is at Loch Oich, which is about 34 feet above high water on the east coast at spring tides. There are 28 locks in the range, 14 being to the west of Loch Oich, and 14 to the east. The locks are about 170 feet in length and 40 feet in width, the rise at each lock being 8 feet. The width of the canal at water surface is 120 feet; at the bottom 50 feet; the depth of water is 17 feet. There were consider-able engineering difficulties to be overcome in the construction of the canal. The object propounded for this national work was the avoidance of the tedious and often dangerous voyage by the Orkneys and Cape Wrath. From Kirkwall's Head on the east coast to the Sound of Mull on the west coast the passage by the Orkneys and Cape Wrath is about 600 miles, while by the inland navigation the distance is not more than 250 miles. By the Cape Wrath passage many shipwrecks had occurred. A large amount of public money has been expended on the works. The returns have been very small in comparison with the cost; once chief work was indeed cut off by the act of the legis-
lature imposing taxes upon the import of timber from the Baltic, in order to encourage the employment in this country of timber of Canadian growth. For a number of yeas the public work was detained in the locks by calm and contrary winds: since 1847 this has been remedied by the establishment of steam-
vessels using this line of navigation. The amount of public money granted by Parliament at various periods from 1803 to 1857 was 1,542,387l. 6s.; the amount received for canal dues, shire dues, &c., to 30th April 1857, was 95,045l.; for towages, 5152l. 6s. 4d.; for rent of houses, stables, lands, 
mills, &c., 11,318l. 16s. 3d.; for interest of cheque bills, interest from bank, &c., 11,767l. 16s. 7d. The cost of construction, repairs, management, law expenses, shipping, roads, &c., from 30th October, 1803, to 30th April, 1857, was 11,655l. 6s. 8d., and the mileage through of steam-tug vessels, 25,452l. The canal rates are in most cases one farthing per mile per ton for the whole passage, the rate for towage being similar. The charge on steam-vessels passing wholly through the canal is 2s. per register ton, whether laden or unladen. In 1848 the commissioners, with the view of inducing a greater number of the Baltic traders to use the passage by the canal, reduced the dues on trading sailing vessels exceeding 120 tons register to 1s. per register ton for the through passage; and to encourage the traffic connected with the fisheries, the towage rates on vessels laden with herrings or salt were reduced by one half. The opening of the Caledonian Canal has given rise to an increased inter-course and traffic between Inverness and Glasgow, and generally between the eastern and western districts of Scotland. Much damage was sustained by the works of the canal in December 1848 and January 1849 by a severe storm and heavy rains. The damage was repaired with great skill and promptitude, and at least cost than was antic-
pated, under the direction of Mr. Walker, consulting engi-
neer to the commissioners, and Mr. George May, their resident engineer. To cover the expense, Parliament granted 10,000l.

to the commissioners in 1849.

(NEW STATEMENT CONCERNING SCOTLAND; FIFTY-SECOND REPORT OF THE COMMISSIONERS FOR MAKING AND MAINTAINING THE CALEDONIAN CANAL; LIFE OF TELFORD, EDITED BY RICKMAN.)

CALENDULA. [ALAUDINE, S. 2.]

CAILOUGH, JOHN CAILLOUGH, one of the most in-
fuential of the recent statesmen of America, was born on
the 18th of March, 1782, at Abbeville, in South Carolina. His father, Patrick Calhoun, was by birth an Irishman, but he emigrated to America early in life, settled in Carolina, and took an active part on the American side during the war of independ-ence. John C. Calhoun graduated with distinction at Yale College in 1804; and, having completed his legal studies in Connecticut, returned to his native place in 1807, to enter upon the practice of his profession. He was elected the following year a member of the South Carolina House of Representatives, where his clear vigorous intellect soon ob-
tained for him considerable notice. In 1811 he was sent as representative to the United States Congress, and the rest of his career in Washington is marked by the discussion of the important measures which in the course of the next five years excited the public mind, Mr. Calhoun played a prominent part, and his fervid eloquence, eagerly defending and stimulating the popular war-cry, won for him a com-
manding position. On Mr. Monroe's election to the presi-
dency of the United States in 1817, he appointed Mr.

Calhoun his secretary of war, a post he retained during the eight years of Mr. Monroe's tenure of office. His admini-
strative services were marked by energy and judgment, and secured his position as one of the ablest public men of his time. On the next election, 1828, he was nominated as a candidate for the presidency, but withdrew his claim, and eventually was chosen vice-president. To this high office he was re-elected in 1829, when General Jackson occupied the office of president; but he differed greatly from Jackson in policy, especially on the Tariff and Bank Charter questions; and in 1831 he resigned the vice-presidency, and was elected by the South Carolina legislature to the Senate. From the end of his term of six years he remained in retirement until President Tyler, in 1843, appointed him secretary of state, an office he held till the election of President Polk in 1845. In that year he again became the representative of South Carolina in Congress. He was regarded as the great leader and representative of the southern states in Congress, and no man was listened to with greater attention by all parties. An intense and fervid
CAL

united, he was yet eminently conservative in spirit, a staunch defender of all southern rights, and the inflexible supporter of the 'institution of slavery. In general and international politics, he commonly took the popular, or, as it was called, the Whig side, and, like Calhoun, had the misfortune to die before his time and before he could bear the fruits of his labors. He died March 31, 1850. Many of Mr. Calhoun's speeches were printed as separate publications about the time of their delivery; and his collected 'Works' are now in course of publication at Charleston and Columbia.

Calhoun was the father of birds belonging to the order Anseriformes and the family Anatidae. It has the following characteristics: Beak as long as the head, straight, slender, flexible, compressed at the base, with the point dilated and smooth. Bill bent in a curve, narrow, pointed, distinctly cleft in the basal furrow, which extends to the smooth point of the beak; wings of moderate length, pointed, the first quill-feather the longest; legs of mean length, naked above the tarsal joint; feet with three toes, all directed forwards, with a very small connecting membrane at their base. GLand, in his 'Birds of Europe,' regards the Knot (Tringa canutus) as a species of Calidris. With this exception, the only British bird which is a species of this genus is G. aranaria, the Sanderling. It is an inhabitant of most of the shores of Great Britain and Ireland. It obtains its food by probing the moist sands of the sea-shores, from which it obtains minute Mollusca, shrimps, annelids, &c. It visits the shores of Sweden, and is stated to breed still farther north. It is said to be found in the east of Ireland, and off Hoy's Bay. It does not appear to breed in the British Islands. (Yarrell, Brit. Birds.)

CALIFORNIA, STATE OF, one of the United States of North America, is bounded N. by the United States territory of Oregon, E. by the United States of New Mexico, and S. by the Mexican territory of Lower California. Its western boundary is the Pacific Ocean, along which it extends from 32° to 42° N. lat., its eastern boundary is defined by a line which runs from 120° W. long. from 42° to 39° N. lat., thence in a south-eastern direction till it intersects the Rio Colorado at 35° N. lat., whence it is continued down the middle of that river to its mouth in the Gulf of California, 32° N. lat. The area is 160,000 square miles, and the population, estimated by the census of 1850, 607,067. The tract of country which now forms the State of California was, until lately, the coast section of the territory of Upper (Alta) or New (Nueva) California, the north-western part of the Mexican republic. It was ceded to the United States of North America by treaty in February 1848, and since has been admitted into the Union as a sovereign state. The extraordinary increase of its population will be seen by the following statement:—In 1852, Humboldt river, which is supplied by the south side of the Sierra Nevada, and the missions, estimated the entire population of Upper California, which included, besides the present State of California, the territory of Utah and (in part) that of New Mexico, at 16,062, of whom 15,062 were 'converted Indians.' The official statement of the father of the United States of California in 1829 was 20,105, of whom 18,763 were converted Indians. After the suppression of the missions the Indians became more scattered, and no official statement of the population was made. The first federal census after thecession of California to the United States was in 1850, when the State of California had a total population of 117,538. In 1852 a census was taken by the State authorities, when the agents' returns gave the population as 294,435; but the Secretary of State, Mr. Bache, official Report, 1852, states that the census agents declare their inability to obtain the numbers of "the whole population of their respective counties," and he thinks it necessary, in order to render an approximately correct statement, to add one-sixth to the number returned. He therefore gives 308,607 as the population in 1858; of whom 210,858 were whites, little more than 30,000 being females, and 108,344 being citizens over 21 years of age; 260,000 were negroes, of whom the females were under 300; 875,043 were American Indians, and 75,043 were foreign residents, of whom about 25,000 were Chinese. California sent in 1857 two members to the Congress of the United States, and like each of the other states two members to the Senate.

Coast-line, Surface, Hydrography.—The State of California owes its characteristic features to two great ranges of mountains, the Sierra Nevada and the Coast Range, which traverse it from north-west to south-east, having between them the splendid valley of the Sacramento and the Joaquin; on the eastern side wide sandy plains, and on the western the narrow slip of coast. The coast of California is generally rugged and precipitous. Beginning at its southern extremity, it makes a bold semi-circular sweep to the north-west as far as Point Orme, thence by a series of projections and indentations, is wide and spacious, and forms an excellent, though at present little-used, harbour. The harbours of San Pedro and Santa Barbara are also available for craft of considerable size. Beyond Point Orme, from north-west to Point Pinos, the southern extremity of Monterey Bay, one of the safest and most capacious harbours on this coast; it is said to be capable of containing at one time the navies of the world. From Monterey Bay the coast continues as before for about 70 miles, in a direction almost the unrivalled bay of San Francisco. The entrance, which is nearly in the centre of San Francisco Bay, is only about a mile wide, but the bay itself opens out for more than 50 miles both on the right and left; its entire length is about 100 miles, with an average breadth of 8 miles, and it has a coast of 375 miles. By projecting points of land, several small inner bays are formed, the principal being San Pablo and Suisun bays. It is land-locked on every side, and quite safe within, except at Suisun Bay, where the current of the Sacramento runs from Yerba Buena Island to the north. This bay is the natural outlet of the valleys of Sacramento and Joaquin, with their wondrous mineral riches and vast agricultural capabilities. Beyond San Francisco Bay is Port Bodega, where was formerly a Russian station. Coos Bay, on the north-west coast of Oregon, is a good passage, but less broken than before, to Point Delgado, beyond which is the broad headland of Cape Mendocino, 40° 31' N. lat., which forms the southern point of the Bay of Trinidad, in which the coast of California terminates. The mountain ranges which constitute the peninsula of Lower California extend undivided into the State of California far north as the snow-capped peak of St. Bernardino, 34° 11' N. lat., where they divide into the two great ranges already mentioned, and run parallel to each other generally parallel direction. The eastern range, called the Sierra Nevada, or Snowy Range, is by far the loftiest, most of its peaks being above the line of perpetual snow; the Saddle Peak is 7300 feet high, the Table Mountain 8000 ft, the Butte 8600, Mount Joseph 10,000, and Mount Shasta at the northern extremity of the range (41° 34' N. lat.) 14,590 feet above the sea. This range is traversed by few and those very elevated passes. North of 39° N. lat. the range of mountains begins to subside, the peaks become lower, the range less in elevation, and the country more level and flat. The coast range has a median mountain, the Mission, on which the head of San Francisco Bay, is 3700 feet above the sea. This range is broken near Monte Diavolo by the united Sacramento and Joaquin rivers; decreases in altitude towards the north; and finally re-unites with the Sierra Nevada near Mount Shasta. From this point northward the surface of the country is wholly mountainous and little known; the Sierra Nevada with its offsets and connected ranges occupying the entire breadth of northern California, and extending northwards to the State of Oregon. To the south of the United States the highest mountains of the Sierra Nevada and the great valley is a line of lower mountains; and from both the Sierra Nevada and the Coast Range lesser lateral ranges and offsets divide throughout California, forming numerous narrow valleys and ranges.

The basin included between the two main ranges, though really one geographical formation, bears the names of the Sacramento and Joaquin valleys, from the rivers which rise in these ranges and flow down the centre of the valley. The basin is divided into two parts, a tract near the centre of the valley, and flow into San Francisco Bay. This fine valley is upwards of 500 miles long and 50 miles wide. It has evidently at some remote period been a bed of large lakes, of which the Sierra Nevada and the Coast Range formed the margin. The waters of this ancient lake have been drained by some perversion of nature having broken a passage through the Coast Range at San Francisco Bay. At the southern extremity of the valley are the Tailare (Sierra) Lakes, which during the wet season extend above 100 miles.
CAL

CAL

99

in length, but in the dry season have little water, and are fordable in many places. Within the last year or two a commencement has been made towards embanking these lakes and draining the rich tract of country hitherto subject to the annual floods. The soil and climate of this great valley vary considerably, but a large part of it is very fertile, including most of the eastern side, which is intersected by numerous streams, along which the land is extremely rich and productive. The surface of the valley is greatly diversified, being broken into rugged hills at its northern end, and in many places along its eastern side by well-wooded spurs from the Sierra Nevada. Towards its southern end by the Tulare Lakes, and along the banks of the two great rivers, it is intersected by valleys of sloping outline used for agriculture into undulating slopes, which break into low hills as they approach the bases of the mountains. The richest and most picturesque part of this fine valley is that central portion of it which embraces San Francisco Bay and the delta of the Sacramento.

The coast district west of the Coast Range—almost the only part of California inhabited previous to the American occupation, but now by no means the most populated part of the country—is full of narrow fertile valleys, the seats in former days of the mission stations, around which the industry of their occupants had caused most of the cereals and fruits of temperate climes to flourish abundantly. Along a good part of the coast the mountains come close down to the sea; but also, the sea has worn away many of the low hills, which in some places reach many miles inland. The country east of the Sierra Nevada, and west of the Rio Colorado, comprising the remaining portion of California, is mostly level, and but little known, owing mainly to the superior attractiveness of the mountains and great valleys, and partly to its being occupied by hostile tribes of Indians. It is believed that white much of it is of comparatively small account, there are very extensive tracts, of arable land, into unappropriated land. The country along the Colorado is supposed to have a rich alluvial soil; but near its entrance into the California Gulf the country about it is dry and barren, and the climate extremely hot.

The two most important rivers of California are the Sacramento and the San Joaquin: the value of the Colorado remains to be fully ascertained. The Sacramento rises at the northern extremity of the valley of the same name; its head-streams issuing chiefly from Mount St. Hilaire and some of its spurs. Its course throughout is generally south, and it receives on its left bank a great number of affluent stream from the Sierra Nevada. Most of these are mere mountain torrents; but several of them, as the Feather, the American, Cosumnes, and the San Juan, are large streams of the same alive from melting snow, and the Sacramento receives the San Joaquin, and the inverse turns abruptly to the west, and soon after expanding to a considerable width drops into San Francisco Bay. The entire length of the river is about 800 miles, and it is navigable for many miles above its junction with the Joaquin, varying from 200 to 300 yards, and it is navigable at all seasons up to Sacramento city, 150 miles from its mouth. The Sacramento is subject to great floods during the wet season, and on the melting of the snow on the Sierra Nevada. The San Joaquin issues from the Tulare Lakes at the southern end of the great valley. Its course is north and north-west, and like the Sacramento it receives numerous tributaries from the Sierra Nevada. During the wet season the San Joaquin is great floods, and the course of the river is marked by small or large islands. Its course is navigable for vessels drawing 8 feet of water up to Stockton, 3 miles above its junction with the Sacramento, and for vessels under 15 tons up to the Tuolumne River. The San Joaquin abounds in fine fish, and the taking and drying of salmon afford employment to many persons. The banks of the river and its tributaries are generally extremely fertile, and agriculture is pursued with much diligence. The country watered by the San Joaquin and its affluents is becoming more and more desirable to settlers, especially along that portion which drains the south-eastern portion of California, and which falls into the Gulf of California, belongs rather to New Mexico, under which it is noticed. Except during the wet season, this river, though draining a country not very fertile, is not of great depth, often not more than 6 feet of water for some distance above its mouth: that part of California which lies in its basin is almost unknown. Along the coast are numerous rivers which rise in the Coast Range and after a short course fall into the Pacific. Among these are the San Buenaventura, San Felipe, San Pedro, and the Smith; many of them are of considerable value for irrigation, and may at some future period be rendered available for mechanical purposes, but none are navigable.

Numerous roads have been formed in the state since its cession by Mexico in addition to those previously existing, and many bridges have been built and ferries established across the principal rivers; but the communications of the state are of little importance and the state of the roads in contemplation the most important is the great line from the Mississippi to the Pacific Ocean. The only line completed in California is that of the Sacramento Valley, 52 miles, the receipts of which in 1856 were 1,354,030 dollars. [Geology.] The Sierra Nevada, with its connected ranges, has for its substratum schistose or talcose slate; quartizes rocks are the prevalent strata covering the slate. In many places a fine white quartziferous granite occurs. In the Coast Range quartz also as well as Sulfur stone is found throughout the lower ranges of hills. Bituminous coal is worked in the neighbourhood of San Francisco Bay; it has also been found about San Diego Bay, and is believed to occur in various localities.

Sir Francis Drake, who visited California, which he named New Albion, in 1678, received such reports of the existence of gold from the natives that he declared it to be his conviction that there was no part of this country wherein there is not some special likelihood of gold. Yet though his story was afterwards often repeated, and the more curious collections of travels, and occasionally in geographical works, no search seems to have been made for the precious metal. The remarkable discovery of the auriferous wealth of California by Mr. Marshall, in the Columbia River, in 1847, by a Mr. Marshall, who was engaged in erecting some saw-mills on the estate of Captain Suter, a wealthy American settler on the Sacramento River. The effect of the publication of this discovery was most extraordinary. The gold in the river's bed, which was rich, attracted multitudes of adventurers to its banks, and the Rightful ownership into the country was quite without parallel in the history of the world. California was at this time occupied by American citizens, and its formal cession soon after to the United States has put into the possession of a people as distinguished for capacity of self-government as any other, not, indeed, as it had hitherto been, of a singularly indolent and incapable race; thereby affording as it were opportunity for the full development of its marvellous capabilities, and at the same time proving against the growth of any nation which might else have ensued. As it was, towns and cities as they were termed, though the houses were commonly only of wood or canvas, sprang up with a rapidity hitherto unknown; the magnificent San Francisco City was for the first time formed of a large number of buildings. The possession of a country of such vast extent with anxious adventurers from almost every part of the world. All ordinary labour was neglected in the rage for gold seeking, which seized indiscriminately on all classes, and the laborer, in a great degree, was obliterating at low prices. The quantity of gold discovered continued for a while to increase even beyond the proportion of searchers for it. By the end of the year 1851 it was estimated that gold to the amount of nearly 150 millions of dollars had been found. No correct estimate is possible, as no official account has been taken of the gold obtained, but from what appears to be an exaggerated estimate the quantity found in 1849 was valued at 40 millions of dollars, and it is believed that the average yearly find has been since then amounting to between 50 and 100 millions of dollars. The quantity of gold-dust and coin manifested and shipped on board steamers and sailing-vessels from San Francisco during 1853 was 46,256,574 dollars; but this does not show the entire amount exported, as large quantities are taken aboard in ships without being entered on the manifests. If 10 millions be added for this the total quantity shipped in 1852 from San Francisco would be about 65 millions of dollars. The quantity received at the mint of the United States during the year 1854 amounted to 183,973,057 dollars. Since that date an Act of Congress has been passed for establishing a mint in California. The total shipments of gold from San Francisco from April 11, 1849, to Dec. 31, 1856, inclusive, were valued at 522,305,688 dollars.

What is known as the Gold Region of California extends for some 500 miles in length, with a breadth of from 40 to 50 miles, following the range of the Sierra Nevada. It occupies the lower mountains of that range lying between the
central mountains and the valley of the Sacramento and the San Joaquin. These mountains average from 4,000 to 8,000 feet in height, and the gold is generally found in gulches and ravines, or in the sandy beds of the mountain streams on their way towards the two great rivers. The geological formation of this region is very similar to that of the gold mountains of Australia and the Ural Mountains of Russia. This gold has been found in situ; it has been in connection with quartz; and the water-worn gold found in the debris of the rocks and the sands of the rivers in like manner shows, by its frequently being carried to a great distance, that it was derived from a quartzose bed. The main gold region, as we have said, is the lower mountains on the west-rn side of the Sierras, Nevada, but gold has been also found in the lofiiter central heights of the Sierra Nevada, and on its eastern side, near the coast. Coal is also found in the Coast Range, especially in the narrow valleys on its western side, and also in the connected ranges. Indeed Drake's words seem now singularly applicable; for there appears to be no part of this country where there is not special likelihood of gold.

Nor is gold the only important metal which abounds, though it is the only one to which much attention is at present given. A mine of quicksilver has long been worked in the western mountains in a lens, in a mixture of copper, of which it is produced near the surface and is easily procured. But the metal is believed also to be widely spread and in valuable veins in other parts of the state. Silver ore of great richness has been found at Monterey and elsewhere. Copper is also present in the thermal springs. These metals are also believed to abound. Coal is profitably worked at San Francisco, and is supposed to exist in extensive beds in other parts.

Biology and Zoology. - The botany of California is of a peculiar and interesting character. It contains among other striking plants some noble pines, especially one called from its discoverer, the Douglas pine (Piinus douglasi), which occurs on the mountains about San Francisco Bay, and grows freely between 1,200 and 2,400 feet, and of a circumference at the base of the trunk of 60 feet. The cones are eaten by the Indians. The P. subalpina, P. Lambertina, and P. nobilis are of less magnitude but still very large dimensions, and great beauty. The live oak (Quercus virgata) grows to a considerable size on the lower hills of the west side of the Nevada, and on it Fremont found unusually large quantities of mistletoe. The white oak is common in the valleys. The maple, ash, beech, and chestnut are the other more usual deciduous forest trees. The firs are more numerous than any other tree, and generally extend south of 39° N. lat. Two or three kinds of Arbutus abound on the banks of the rivers and the margins of the forests. The Scilla quiejina grows everywhere along the coast; its root is the quiquam of the Indians, with whom it is considered a delicacy. The Fibres of the hemp (Cannabis) and the Helonias tanax are made by the natives into a very tough cord for horseicking, &c.; and the amole and samate are used by them for rope. Large numbers of Polemoniae, especially some beautiful specimens of the Leptosiphon and Gilia; some curious plants belonging to the genera Nema- phila and Esmemanns; several new genera of poppies, Bachechloca, lupins, Calochortus, Cymbobatrach, Callitropsis, Bredex, &c. stamp the vegetation with a character quite unlike that of any other part of America. The black bear, theizzly bear, and the barren-ground bear, the racoon, American badger, glutton, ermine, wassel, mink, mart, and skunk are common in many parts; as are also the tiger, or musk-vat, about the mouth of the Sacramento; all of these are much sought after for their skins. Several kinds of wolves, foxes, and lynxes abound on the interior forests of the north, where they prey on the numerous deer and other animals which frequent those regions. Of the deer, the moose, the black bear, and the long-tailed or jumping deer, the elk, and the prong-horned antelope (A. fuscus) are the most plentiful. Mountain sheep abound. The bison is only occasionally met with. Among birds the first place is due to the great California vulture, also the Sturmgraup. California has no birds of the way the latter is found only to the South American condor, in size, and very similar to it in its hirns. The black vulture, the turkey buzzard, the golden eagle, the bad eagle, the p-reigning falcon, the jay, the loag, and several others animals and species as well as owls, are more or less common. Most of the ordinary European singing birds, swallows, woodpeckers, &c., or birds to which similar names have been given, are also found. The humming-bird is common in the south. The grasshopper, or locust, is also very common of this kind; than have been found in any other country. The bays and inlets of the coast are swarm with swans, geese, ducks, curlews, and most of the other ordinary wading and swimming birds. Large numbers of white pelicans frequent the coast. They are sometimes shot, measuring 10 or 12 feet across the wings.

The coasts and rivers of California alike yield an astonishing number and variety of fish. In some of the rivers as high as 100 pounds, which are sometimes shot, measuring 10 or 12 feet long, and weighing nearly 500 pounds. Macerel, pilchards, and sardines are also common in the coast waters. The clams are also abundant. Oysters of excellent flavour and most other shell-fish are found. But though fish is so abundant, the fisheries are at present little heeded.

Climate. - California has a dry and a wet season; the dry season lasting from about the middle of May to September or October, the wet season setting in early in November and lasting till May. But there are considerable variations, both in the temperature and in the amount of rain, in different parts of the state. In a certain part, north of 39° N. lat., for instance, the air during the dry season is much less parched and rainy than is elsewhere. It is much hotter and drier along the coast than in the interior, especially towards the north, where the climate is more temperate than in the south. The climate is in general one of great diversity and variety, being at times excessively hot and parching. In summer the coast is visited by heavy fogs, and a cold wind sets in regularly towards noon from the Pacific, and continues to blow with increasing force and keenness till late at night. In winter, when the cold is modified, and the temperature becomes equal and agreeable. Throughout the great valley of the Sacramento and San Joaquin, the mid-day heat is so great as to render labour in the open air everywhere unpleasant, and in many parts positively dangerous. The soil along the great valley is generally extremely rich. This valley has evidently been at some remote period the bed of a vast lake, and the rich alluvial soil now justly exists by irrigation to render it capable of producing almost every variety of crop. The banks of the rivers require proper embankments to prevent the present often destructive floods, and to permit the full development of its agricultural capabilities. Tobacco, rice, maize, and most of the plants excepting those of the tropical regions, grow very well in the United States, flourish in the sheltered valleys connected with this principal valley, while in the main valley itself most of the cereals produce extraordinary crops, and grapes, peaches, and nearly all other fruits of a moderately warm climate, are raised in abundance. These fruits are generally very sweet and nutritious, affording excellent pasturage for cattle. North of 39° N. lat. are extensive forests of pine and oak. The valleys along the coast produce all the cereals, and all or nearly all the vegetables of the temperate and colder parts of Europe. Peaches and a few melons are raised on some few hills; the produce from nine counties in 1852 was returned at 5,533,656 pounds. Tomatoes are extensively cultivated in parts of the great valley; 1,039,600 bushels were raised in 1852 in Sacramento county alone, and in the same county 250 acres were planted with melons. In the county of Santa Barbara, on the southern part of the coast, 1370 barrels of olives were gathered; and in this and the adjoining county of Los Angeles 73,462 gallons of wine, and 73,036 gallons of brandy were made. Agriculture has however hitherto been comparatively neglected, but as more attention is being paid to it the various capabilities of the soil are becoming more apparent, and there can be little doubt that California is destined to take a high rank as an agricultural country.

It is usual in taking the census of the various states of North America to ascertain the quantity and value of the various productions. In the state census of California for 1852 these returns are very incomplete, but they were sufficiently accurate to show that the Union obtained a very favorable view of the position of California in reference to other states of the Union, which is at once so curious and interesting that it may be worth while to quote a few of the results of this census. In barley California surpasses every other state in the Union except New York, and already raises half as much as is produced in the whole Union besides: in oats it
cultivates more than three fourths of its sister-states; in
wheat it surpasses ten of the states; of maize it produces
less than any state, and it ranks twelfth in small grain,
and grows one-fifth of the quantity produced by the rest of
the Union; in beans it surpasses nine of the states; in hay,
though only half of the counties made returns, it surpasses
nine states; and in fruit it exceeds all the states in variety,
and one-half in quantity. In the number of horses it exceeds
15 of the states; of mules 26; of milk cows 12; of work-
oxen 8; of sheep 4, and of swine though the returns of both
these are very imperfect) 3. In live stock it surpasses 22 of
the states in beef cattle, 14 in horses, 11 in mares and 28 in
sheep and swine.

The trade of California is chiefly carried on through the
commerce of the State of California, is partly shown by the statement
of the number and tonnage of the vessels which entered and
cleared at San Francisco in 1852:

Entered.—Sailing vessels 87 of 326,138 tons. Steamers. 127 118,876

Total 1003 445,014

Of these, 40 vessels of 16,856 tons burden were British, and
554 vessels of 317,292 tons, vessels from foreign countries.

Cleared.—Sailing vessels 1331 of 356,092 tons. Steamers. 158 127,047

Total 1489 483,139

Of these, 1121 vessels of 361,168 tons burden were America-
ian. In 1849 the tonnage of the vessels entered at San Francisco amounted to 313,351 tons, of which 247,417 tons belonged to the United States. The number of passengers may be taken for an average of 15,000, and the number of Rep.-3entatives of 36 members, el-ch-t for one year; the
sessions of the General Assembly are held annually. The
magistrate is elected for two years; his salary 6,000 dollars
per annum. The revenue for the year ending June 30, 1856,
was 733,350 dollars; the expenditure for the same period was $1,368,514. The total debt of the State, Jan. 1, 1857, was $4,138,977.
The judicial power is vested in a supreme court and district
and county courts. The supreme court consists of five jurists,
or chief justices, who have an annual salary of 8,000 dollars, and two
associate justices, each of whom has a salary of 6,000 dollars a
year. The magistrates are elected by the people for six years,
and no one is elected that goes out of office every two years.

The first judges of the district courts were chosen by the legis-
latue, but all future judges are elected by the people;
there are fifteen district judges, with annual salaries varying
from 2000 to 3000 dollars. A county-court judge is elected
in each county for four years.
The constitution directs that a superintendent of public
instruction shall be elected, to hold office for three years;
and that the legislature shall establish public schools, in which
children shall be instructed during the day free of charge.

History.—California was discovered by Cabrillo in 1542.
It was next visited in 1576 by Sir Francis Drake, who named it New Albion. It was first colonized in 1768 by the Sparsida, who established various places, chiefly west of the Coast Range, as military posts (presidios) and religious
stations (misions). There were four of these military
and twenty-one missions; and while California re-
mained subject to Spain the actual direction of the country
was in the hands of the priests, the governor having very
little influence over them. In 1821 the country became
independent, governed by Mexican priests and native Indians
in villages, and taught them to cultivate the soil, and gave
them little instruction either religious or secular.
According to the latest account published by the priests there
were above 18,000 in these post 'converted Indians,' who spoke twenty different languages. On the separation of Mexico from Spain the missions were broken up, and the Indians returned pretty g-nearly to their native state. After the declaration of Mexican independence a good many
Americans and Californians emigrated to California,
with the purpose of hunting or traffic, and several Americans
met in the neighborhood of San Francisco Bay. The governors
appointed by Mexico were unable to maintain tranquillity in the province, and a new insurrection broke out in 1850.
A successful revolt, mainly excited it is said by the foreign
residents. The government was overthrown without blood-
shed, and the governor and other officials were put on board a schooner and shipped off to Mexico. The Mexican government, the United States, California, and Mexican governors, and the country continued nominally subject to Mexico. It remained however in a state of anarchy, and for some time before its cession had become virtually under the control of American citizens. The war between Mexico and the United States, California was, as already mentioned, formally ceded to the United States by treaty in February, 1848; and on its rapid growth in wealth and population, consequent on the gold discoveries, it was a year or two later admitted into the Union as a sovereign state.

(C.-Von, *Statistical Gazetteer of the United States, 1853; American Almanac: Fremont, Wilkes, and various Travels, Journals, &c., in California; Visits to Gold Digging, &c.)

CALIFORNIA. A genus of plants belonging to the natural order Polypodaceae, of which one species, *C. Pallidula*, yIELDS in its roots an amylaceous gummy matter, on which the Calamabcd in feeds in times of scarcity. The fruits and branches are acid, and are chewed by the same people to alleviate their thirst. This plant is desis sent of lemons, and grows in great abundance on the sandy steppes of Siberia.

CAMBERWELL. [Surrey.]

CAMBRIDGCE. [Cornwall.]

CAMBRIDGE, one of the principal cities of England, a river of Africa, which discharges itself into the Bight of Biafra and into the same estuary as the M-layer, about 45 miles E. from Fernando Po. It has a bar across its mouth, with an average depth of from 15 to 20 fathoms a mile or two over it. Of this river little is known beyond a few miles above the estuary; but on this coast, it has been long known to be a great mart for slaves. Palm oil and ivory are obtained here; the latter is considered very fine. The system of traffic is by barter. This river is separated from those to the westward by high land called the Cam-roon Mountains, the highest peak of which rises to 13,000 feet above the sea, and is generally capped with snow. The name is derived from the Portuguese word for shrimp, of which there is a great abundance. Each side of the river claims the rights of friendship; but property must be purchased by presents before any traffic is commenced.

CAMPDEN, CHIPPING. [Gloucestershire.]

CAMPBE, a genus of plants belonging to the natural order Lecanoreae, or Lecanoraceae. This genus was constituted by Nees von Esenbeck for the *Lecanora Campaniformis* of Kämpfer, the plant which yi-las the Camphor of commerce. It is known by its hermaphrodite panicled naked flowers; 6-chit papery calyx; 6-leafed, oblong, obtuse, the inner row with two stalked glands at their base; the anther 4-celled, the outer turned inwards, the inner outwards; the fruit placed on the oblongical base of the calyx; the leaves tripinnate, glandular in the axils of the principal stems; the leaflets decurrent along the midrib. C. officinarum, the Camphor Laurel, is a tree with lax smooth branches; the leaves are bright green and shiny above, paler beneath, and somewhat coriaceous, with a sunken gland at the axis of the principal vein, projecting at the upper side, opening by an ovate pore beneath. This plant is a native of Japan and China, and is cultivated in most of the warmer parts of the world. The Camphor of commerce is yielded by this tree, which is cultivated most extensively in the island of Formosa, from whence it is taken to Canton, which is the principal market for Camphor. [Caphhorse.]

CAMPION. [Lycens, s l; Silene.]

CAMPBELL. [Strathclyde.]

CANN. [Leith, East.]

CANNON. [St. Louis.]

CANNON. [Montreal, and Quebec. [Montreal, Quebeck.

Quercus.* The other towns are Rivers, Sr. Hyscinthe, Sherbrooke, and Sorel. Three Rivers is prettily situated at the junction of the St. Francis and the Richelieu rivers, and has a population of 4036. There are iron mines near the town. There is a considerable trade in pot- and pearl ashes. Three Rivers is one of the depots of the northern line of steamers, and it is the chief port of some important investment in a commercial point of view. St. Hyacinthe, population 3313, in St. Hyacinthe county, is situated on the left bank of the Yamaska River, about 30 miles E. by N. from Montreal. It is the seat of a college. Sherbrooke, population 11,000, is the chief town of the district, and its principal business is situated at the junction of the Magog with the St. Francis River. Its extensive command of water-power gives it great facilities for manufactures. The chief public building here is the court-house and jail. Sorel, or William Henry, population 10,000, is situated on the Richelieu River, on the old road to St. Lawrence, is likely from its advantageous situation to be of much greater importance than it has yet attained. By the Champlain Canal there is communication between Lake Champlain and the St. Lawrence. Sorel is also a railway along the same line of route.

Upper Canada, or Canada West, is divided into 42 counties, as follows:—Addington, population 15,165; Brant, 26,485; Bruce, 2637; Carleton, 51,397; DUNDAS, 13,611; Durham, 26,396; Eastcloth, 39,485; Frontenac, 17,552; Grey, 20,733; Grey, 13,517; Glengarry, 17,926; Grenville, 20,707; Haldimand, 18,788; Halton, 18,328; Hastings, 31,977; Huron, 19,194; Kent, 17,409; Lambton, 10,813; Lanark, 14,375; Leeds, 15,260; Lennox, 7,555; Middlesex, 29,896; Middlesex, 13,339; Norfolk, 21,281; Ontario, 30,576; Oxford, 32,638; Peel, 24,816; Perth, 15,546; Peterborough, 15,537; Prescott, 10,457; Prince Edward, 18,857; Renfrew, 9415; Russell, 2870; Simcoe, 27,165; Stormont, 14,643; Victoria, 11,197; Wellington, 29,537; Wellington, 27,966; Welland, 20,141; Wentworth, 49,619; York, 79,719; population of Canada West, 115,004. Total population of Canada, 1,842,565.

Canada West contains the cities of Toronto, at present the seat of the provincial government, and Kingston. [Tonroor.] Hamilton is beautifully situated at the western extremity of Burlington Bay, near the shore of Lake Ontario. It was founded in 1813, and became an incorporated town in 1839; the population in 1851 was 14,112. The construction of the Burlington Canal, a short cutting which opens a clear navigation into Lake Ontario, and the improvements of the Desjardins Canal, five miles long, which connects Hamilton with the manufacturing town of St. Catharines, has greatly increased the trade of the place. It is the district town of Gore district, and as such contains the court-house for the district and other public buildings. The streets are well laid out, and many of the houses are built of stone. There are two market-houses, one of them being the old Custom-house, and the other used for the post-office and for holding the market. There is a tavern, a
d house, a post-office, and a theatre. A place is places of worship for Episcopalians, Presbyterians, Wesleyan Methodist, Independents, Baptists, Roman Catholics, and others; news-rooms; and mechanics institute. Good roads lead in all directions from the city, and several numerous stage-coaches keep up communication with the surrounding districts. Steam-vessels ply regularly during the season to Toronto and to Queenstown and Niagara. Hamilton has much increased in commercial importance of late years. Kingston, population 11,685, situated on Lake Ontario, distant 199 miles S.W. from Montreal, and 177 miles E. N. E. from Toronto, was incorporated in 1838. It is advantageously situated at the beginning of the Rideau Canal and the Cataract River, and is important in the system of internal navigation, as a commercial point of view, being the key of the central St. Lawrence, as Quebec is of the river's seaward extremity. In its neighbourhood is Navy Bay, a narrow and deep inlet of Lake Ontario, which is the chief naval station on the lake. The market-house, which contains also the post-office, the town-hall, and several public offices, is a handsome stone building of considerable dimensions. There are places of worship for Episcopalians, Presbyterians, Wesleyan Methodists, Baptists, Roman Catholics, and others. There is also a hospital, an mechanics institute, and news-rooms. Ship-building is carried on. A bridge nearly 600 yards long crosses the river Cataract at Kingston. There are several public buildings in the town.
River, population 1830, is finely situated, the banks of the river in the vicinity of the town being very beautiful. The town received in 1842 a charter to hold a fair twice a year. There are Episcopal, Presbyterian, Methodist, Baptist, and Roman Catholic places of worship, a court-house, news and reading rooms, a bank, a post-office, and many of the habitations. The town is in the neighbourhood of the town. Barrie, population 1837, commenced in 1832, is now the district town of Simcoe district. There are in the town a court-house, a post-office, a district town of Niagara, 48 miles E. from Hamilton, is one of the oldest towns in Canada, and was for five or six years under the name of Newark the capital of the country. It has several churches, a town-hall, and a court-house. The Niagara Harbours and Dock Company, incorporated in 1830, have constructed numerous wharfs and docks, and the Great Western railway are among the public buildings of the town. There are good roads in the vicinity. Machine-making, tanning, brewing, &c., are carried on. Niagara, population 3540, the chief town of Bathurst district, distant about 40 miles W. from Brockville, was laid out by the government in 1816. It stands on the river Ty, which is made navigable to the Rideau Canal by a branch canal about 11 miles in length. The town contains several places of worship, a court-house, and a jail, and many other public buildings. It is a healthy place, and only a few miles from the town. Peterborough, population 2911, occupies a beautiful situation on the Otonabee or Trent River, about 34 miles N.N.W. from Cobourg. It was commenced in 1826, is well laid out, and has a handsome court-house and jail. The town is called Peterborough East. Most of the places of worship are built of stone. On an elevated site behind the town is the city-house and jail, a handsome stone edifice. There are here woolens, manufacturers, fulling mills, saw-mills, chair-factories, breweries, &c., Pitson, population 1668, chief town of Prince Edward district, is finely situated on the Bay of Quinté. It is an old town and contains many good stone houses. Steamer calls here on their passages between Kingston and New York. There is a church of worship, a court-house, a jail, and a library. A good deal of trade is carried on. Wheat, flour, butter, leather, &c., are exported. Port Hope, population 2476, on Lake Ontario, about 10 miles S.W. from Cobourg, between Toronto and Kingston, is built on the side of a hill commanding interesting views of lake and inland scenery. It contains some handsome buildings, including four places of worship. Wheat, flour, and timber are the chief exports. Prescott, population 2156, on the St. Lawrence, about 18 miles N.E. from Brockville, possessed considerable trade previous to the opening of Rideau Canal, but since then it has not made rapid progress. Among the buildings are four places of worship and a custom-house. At this place the river is about eight feet deep, but a few miles below the village, where the pearl seams is exported. Sandstone, population not given, lies, sately, on the Detroit River, is finely situated and well laid out. It is one of the oldest towns in Canada, and has a handsome market-place. There are many flower-gardens and orchards are kept by the inhabitants. The Épican and Methodist have places of worship in the town. Simcoe, population 1452, the chief town of Talbot district, is situated near the shore of Lake Erie, about 24 miles S. W. from Brantford. Grist and saw-mills, a carding-machine and rolling-mill, with other establishments, furnish employment. St. Catherine's, population 4388, on the Welland Canal, about 12 miles W. from Hamilton, is a principal station on the London and Hamilton trade. Ship-building is carried on. Great quantities of flour are annually exported. There are six places of worship. Woodstock, population 2112, chief town of Oxford county in the brock district, about 32 miles S.E. from London, is pleasantly situated. It is called brock, and has one of the most pleasant market places in the United States. Woodstock, forming one street of about a mile long. There are six places of worship, a court-house, and a mechanics' institute. Considerable trade is carried on. Of the population 1841, 9261, as many as 693,628 are natives of Canada of French origin, and 125,560 are Canadians of other than French origin; 61,490 are of Irish origin; 14,686 of Scotch; 12,482 are from the United States of North America; and 11,230 from England and Wales. These are the most important of the E. and W. and the canton, and of our own colonies.

In Can West, the population of which is 822,004, the Canadians of French origin number 26,417, and the Cana-
of the whole of Canada, of which the total population is 1,542,265, the seven principal items stand as follows:—Canadians of French origin, 305,945; Canadians, not French, 561,673; Irish, 227,766; English and Welsh, 92,698; Scotch, 76,511; natives of the United States, 43,732; natives of Germany and Holland, 9837. With respect to the surrender of Canada to Great Britain, the population was chiefly French, and located in the lower province. Although this class has been much increased by immigration, the total number is about 1000 per cent. The progress of Canada West has been still more remarkable. In 1791, the date of the Constitutional Act, the population was 50,000; in 1811 it was 77,000; in 1824 it was 151,097; in 1826 it was 261,060; and in 1824 it was 486,056; and in 1851 it amounted to 958,004.

The amount of immigration into Canada is stated in a separate article. [EMIGRATION, S. 2.]

In January 1857, the total length of main railways in Canada was above 1000 miles. These railways consist of two principal lines, the Grand Trunk Line and the Great Western Line, which are united at Toronto, and form a continuous railway from St. Thomas, east of Quebec, to the west of Montreal. The Grand Trunk Line proceeds from St. Thomas 49 miles to New Liverpool, opposite Quebec, and thence by Richmond (where it unites with the line from Portland, in the State of Maine) to Montreal 170 miles, then through a branch southwards to the St. Lawrence and the Upper Lake. From Montreal, by the line proceeding through Prescott, Kingston, and Toronto, to Stratford 421 miles; total 640 miles. The Great Western Line extends from Toronto through Hamilton and Chatham, to Windsor, opposite Detroit, 229 miles. There is an independent line from Niagara Falls to Hamilton 54 miles. This gives a total length completed of 903 miles, exclusive of the Ottawa branch and other smaller railways.

The revenue and expenditure in each year, from 1846 to 1853, are as follows:

Canada receives from the United Kingdom, 70% of its imports, 80% of its exports, 90% of its manufactured goods, 95% of its machinery, 96% of its newsprint, 97% of its railway rolling stock, 98% of its coal, 99% of its iron and steel, and 100% of its pottery and glassware.

The exports of Canada are:—To the United Kingdom, pot and pearlashes, wheat, flour, and timber; to the West Indies, sugar, molasses, coffee, rum, and hard woods; to the United States, beef and pork, biscuit, rice, and tobacco.

The imports of Canada are:—From the United Kingdom, coal, iron, machinery, textile goods, and manufactured articles; from the United States, flour, corn, and hides; from Brazil, coffee; from Russia, tea; from China, silk; from India, calicoes; from Japan, silk; from Portugal, tobacco; from France, wine; from Germany, iron and steel; from Holland, machinery; from Belgium, cotton goods; from Italy, wine; and from Canada, timber, flour, and grain.

The government of Canada is a constitutional monarchy, with a Governor-General and a Senate and House of Commons. The Senate is elected for 9 years, the House of Commons for 5 years. The capital is Ottawa.
pretender to the Spanish throne, was the second son of Carlos IV, of Spain, and was born on the 20th of March 1788. Left chiefly in the hands of priests, to whom the superintendence of his education was committed, he lived in comparative obscurity during the dominion of Godoy. On the first abdication of his father and the accession of his brother Ferdinand VII., Don Carlos was sent to meet Bonaparte, who had announced his intention to visit Spain. The young prince, regarding Genoa as safe, left Madrid in Spain and made in effect a prisoner, and Ferdinand, like his brother, was soon found himself also in the hands of the French. Bonaparte next compelled the weak ex-monarch of Spain to pro-
cede to France, where, after having spent some time with the French, he was sent to Vienna, where he was placed in a hotel, and was then under the hands of the Quen and the subsequent rising in favour of the Count de Montemolin was easily suppressed. Don Carlos was permitted in 1847 to remove to Trieste, where he remained in fact a prisoner till his death, March 10th, 1856.

CASHHALTON. [Syrac.]
CARDHA. [Lisburn.]
CASEARIA, one of the five genera of plants constituting the natural order Sambuceae. Several species of the genus are used medicinally. The leaves of C. sitifolia are astrigent, and in the Brazils are applied to recent wounds. A decoction of the leaves of C. tonca, called by the Brazilians Cha de Frade and Lingua de Fin, is used in fevers and inflammatory disorders. C. astrigera is used as an external application on account of its astrigent properties. C. Anamans, a species of C. eucalyptus, is eaten, but the root is bitter and purgative.

CASEIN. [Chemistry. S. L.]
CASTAÑOS, FRANCISCO XAVIER, the most eminent Spanish general in the Peninsular War, was born at Madrid, 24th February, 1766. His father, who was a military officer, procured him a captain's commission at the age of twelve, and he remained in the service till he was ninety-six, being then probably the oldest soldier on record. In his early years he was sent with General O'Reilly to the court of Fréderique the Great to learn the Prussian tactics, and he passed through various grades in the Spanish army without achieving any high reputation till the invasion of Spain by Napoleon I., when he was fortunate enough to furnish an example of series of victories against the French, which terminated in the downfall of their power. On the 32nd of July 1808, eighteen thousand French, commanded by General Dupont, laid down their arms and surrendered to the Spanish army, under Castaños, at B. ylen. It is stated by Lord Holland, in his 'Reminiscences,' that when the French general delivered his sword to Castaños, he said, "You may well, General, be proud of this day; it is remarkable that I have never lost a pitched battle till now; I have lost my army.

"It is the more remarkable," was the Spaniard's quiet reply, "because I never was in one before in my life." The chief merit of the victory has, however, been ascribed by many to the second in command, Aloya Reding, a Swiss patriot, who, from the time he defended the gates of Madrid, when Napoleon had entered the service of Spain. The effect of this great battle was to drive Joseph Bonaparte from Madrid, and on the 23rd of August Castaños made his triumphal entry into the capital, where, on the next day, Ferdinand was proclaimed. Later in the same year, in November, Castaños was defeated by the French at Túmeda, and he held but a subordinate position to the Duke of Wellington and Marshal Beresford during the remainder of the war.

Luis Philippe assigned him a residence in the city of
Bourges, where he was joined by his family, and where for some years he maintained a mimic court, in which was observed all the elaborate etiquette of the Spanish monarchy. At length, sick of hope deferred, he in 1845 formally relinquished his Spanish crown in favour of his eldest son Don Carlos Luis Maria Fernando, Count de Montemolin. The abdication of Don Carlos was strongly opposed by his wife, the Princess Maria Theresa (daughter of John IV. of Portugal), and by his leading supporters, including Genoa and the hands of the Qen and the subsequent rising in favour of the Count de Montemolin was easily suppressed. Don Carlos was permitted in 1847 to remove to Trieste, where he remained in fact a prisoner till his death, March 10th, 1856.

Ferdinand, who was very fond of him, circulating amongst the lower classes. Among other postures of dignity, he held the title of Count of Barajas, a member of the royal family of Spain. He died at Madrid, on the 24th of September, 1853, and his remains were lamented with a public funeral.

CASTEL VETRANO, a town in the province of Trapani, in Sicily, is situated near the left bank of the Delta, 30 miles E. from the town of Trapani, about five miles from the nearest point of the south coast of the island, and has a population of about 13,000. The town is famous in works of coal and alabaster. It is built on a hill, and is an old city, several churches, convents, and palaces. The country round Castel Vetrano is fertile in wine and rich pastures. A few miles from Castel Vetrano, to the south-eastward, are the ruins of the ancient Selinum. This ancient city is covered with broken columns, capitals, and palaces. The ruins are of Doric, and of large dimensions; they are called 'Giants' Pillars' by the peasantry. A few columns are still standing. Some finely sculptured metopes were discovered at the base of the façade of the central temple in 1822. There are ruins of six temples in all.

CASTELLAMMARE, the chief town of a subdivision of the province of Naples, in the kingdom of the Two Sicilies, is situated near the head of the Bay of Naples, on the lower slope of a low hill, at an elevation above the level of the sea of 634 feet (or about 200 metres). The town is 15 miles by railway S.E. from Naples, and has a population of 18,000. It is connected by a branch railroad with the Naples-Nocera line, the first railway opened in Italy, on the banks of the river Agri, on the one side, and the mountains of the Olympos on the other, which was ruined by Sylla in the Social War, and afterwards covered by ashes from Mount Vesuvius in the eruption of A.D. 79. During this eruption Pliny the elder lost his life at Stabiae. The hill above Castellammare is called Monte Quiri-senna, from its shrub livery; it is covered with villas and cottages; among the latter is the royal casino of Qui-senna, founded by Charles II. of Anjou, and now the property of the Russian prince Lieven. Behind the hill rises the imposing mass of Monte Sant'Angelo, which with a circumference of 28 feet is perfectly bare and without vegetation, and forms a conspicuous object between the bays of Salerno and Naples. The town derives its name (signifying 'castle by the sea') from its castle, which was erected by the emperor Frederick II., surrounded by walls and towers by Charles I. of Anjou in the 13th century, and subsequently strengthened by Alfonso I. of Aragon. The town was sacked by the army of Pius II. in 1461, and again in 1654 by the Duke of Guise. The harbour has a depth of three to four fathoms with a good anchorage, protected by a mole. In connection with the harbour are a bagnio for galley slaves, and a royal arsenal and dockyard, where the ships of the Neapolitan navy are built. These establishments contribute to the prosperity of the town. Castellammare has been celebrated since the time of Galen, for its mineral springs, which are very efficacious in gouty and rheumatic afflictions. There are twelve of these,—four chalybeate, four saline, and four sulphureous,—and they all rise at the base of the Monte d'Auro, within a short distance from one another. They are all of moderate temperature, and seldom exceeding 65° Fahr. Great numbers of visitors frequent Castellammare and its delightful neighbourhood during the summer and autumn; the temperature is 8 or 10 degrees lower than that of Naples. The town, which gives title to a bishop, and has a handsome cathedral, is well built, partly on the lower slopes of Monte d'Auro, but chiefly on a shelved beach commanding a view of the whole bay of Naples. The town is celebrated for the fertility of its soil, for its coal, timber, and machinery. Among the industrial products are macaroni, silk and cotton goods, and sail-cloth. The fisheries along the coast employ a good many hands. Some excursions are made among the ruins of Stabiae in 1745 brought to light a few remains of sculptures, some pottery, and paintings, which are now in the Museum of Naples.

There is another Castellammare, or Castellammare, in the province of Trapani in Sicily. It is situated on the southern slope of the Monti Segesta, from the town of Trapani, 17 miles W.S.W. from Palermo, and has about 6000 inhabitants. The town, which is ill-built and dirty, is named from its old decaying castle. It carries on a considerable trade by sea, and has large granaries; the exports are gravel and lime. The remains of the ancient Segesta are near Castellammare; they consist of a Doric temple in tolerable preservation, the ruins of a theatre, and a part of the city wall. Castellammare would not have been of the importance of the port of Segesta [Trapani] had not the town been destroyed by a water-spout in December, 1851.

CASTLE ACRE. [Norfolk.]

CASTLE BLAYNEY. [Monaghan.]

CASTLE CARY. [Somersetshire.]

CASTRENN, MATTHIAS ALEXANDER, one of the heroes and martyrs of modern philosophy, was born on the 2nd of December 1813 in the province of Uus-vo in Finland, not far from the boundary between Finland and Lolland, a little island which belonged to Sweden, and is now a part of Denmark. The manor house which he occupied was usually resort to visit the peasant men of the midnight sun. He received his early education at Tornoe, and afterwards went to Helsingfors to pursue his studies at the university, where he was removed to the university after the conflagration of Abo. One effect of the transfer of Finland from Sweden to Russia had been to lessen the importance of the Swedish language, which had up to that period occupied much the same position in Finland which the English does in Wales, but which then ceased to be the language of the government, though it continued to be that of the educated classes. A lively interest was awakened in the Finnish, the old language of the country, which is still spoken by the peasantry, and which some recent philologists have recently been investigating and discussing in Europe. Of the students at Helsingfors who followed up this study none were more enthusiastic than Castrén. He made a resolution to devote his life to the language and literature of his country, and undertook this an ideal vocation. He commenced a course of inquiries into the mythology of ancient Finland, and found that to complete his views it was desirable to ascertain with more exactness than had hitherto been thought requisite the mythology of the Laplanders, he looked about for the means of making one journey into Lapland, and studying the language and religion of the Lapps. In 1838 an opportunity was presented itself, and he set out with three companions on a tour, which before its completion took him to Utsioki and the great lake of Enä. The journey was, however, not without disaster, for he broke all their stores on their backs, and their journey both out and home was an almost uninterrupted series of labours, hardships, and privations. Castrén could learn less of the Lapland mythology than he had expected, for although the conversation of many of the tribes from heathenism had only taken place in the 18th century, the Christian Lapps were so devout that they often spent twenty-four hours in succession in religious exercises, and many of them knew the whole of the Lapland mythology by heart. Although his observations were regarded with proportionate abhorrence. On his return he learned that the Imperial Academy of Sciences at St. Petersburg contemplated sending an expedition to Siberia to prosecute researches in ethnology, and he pushed himself in consequence to become a fellow-citizen of his newly founded fellow-philosopher Sjögren to undertake the task. For the time he was disappointed; but the Literary Society of Finland raised a scanty subscription to send him on a mission to Russian Castrén, to collect lillas, legends, and traditions illustrative of his favourite Finnish mythology, and he was remarkably successful. Soon after his return in 1841, he published, at Helsingfors, a transliteration into Swedish, in the metre of the original, of the great Finnish poem 'Kalevala,' the discovery of which by Dr. Lounrot, who first noted part of it down from the lips of the peasantry, has made an epoch in the history of Finnish literature. It was this translation that first brought the poem into general note; and, certainly, since this time, it has been the subject of serious examination, of discovery of the kind, real or supposed, has produced an equal sense ion. 'Hiawatha,' the recent poem of Professor Longfellow, though purporting to be an embodiment of the traditions of the North American Indians, is borrowed from the 'Kalevala' in its general style, in its peculiar metre, and even in its more prominent verses. Soon after its publication Castrén set out on his third philological journey, which appears to have been made in his coat and at the expense of Dr. Lounrot, and afterwards found his way to Utsioki, and finally to E. coast. He visited first to his old quarters at Enä, then to Kola, the capital of Russian Lapland, and finally to the Somoyed on the coast of the White Sea. Here, with only fifteen rubles to keep him from starvation, he struck up an acquaintance with some of the native Somoyed, and acquired an occasional glass of brandy undertaken to teach him the Samoyed language; and in the heat of this man he passed
nearly the whole of a summer, engaged in the study. Towards the end of his travels, which lasted for four years, from 1845 to 1849, he crossed the Tundras, or deserts of European Russia, between the White Sea and the Ural, where not even the rein-deer can feed without the wiry blast and live. Philology has its martyrs as well as religion. Castrén returned with his constitution ruined.

While on his travels he had written most interesting and amusing letters of his adventures and discoveries, which were printed in the 'Soomi,' an excellent periodical in the Swedish language published at Helsingfors. Many communications from him on learned subjects, chiefly written in German, appeared at the same time in the 'Bibliotheca,' the learned periodical of the Swedish Academy, and his name was universally known as that of a philologist of the first rank, but it was not till March 1851, on the occasion of a visit of the Grand Duke Alexander, the present Emperor of Russia, to the University of Helsingfors, that he was introduced to the position of a 'private-docent,' or private tutor, to that of professor of the Finnish and old Scandzinavian languages. One of his duties was to deliver a course of lectures on Finnish mythology, which he immediately commenced composing, but before they could be finished he was no more. He died at Helsingfors on the 7th of May, 1853, from the effects of his smoked journey.

The translation of the 'Kalevala,' and some of Castrén's other works, have been already mentioned. His lectures, 'Vedtheres ädelspråk,' in which the whole of Finland comes over the desk in its bearish philological character:—'Elementa Grammatices Thromione,' 'Koepio, 1845, 8°; 'Elementa Grammatices Syrjovne,' Helsingfors, 1844, 8°; 'De Affilia Personum Lignarum Altaicarum,' Helsingfors, 1850, 4to. There is also an Osian Grammaticon, containing a portion of a work called 'Nordische Reise und Forschungen,' which was commenced at St. Petersburg in 1840. It need hardly be added that all these works are of the highest value to those who take an interest in what is called the Ugrian family of languages, possessing some curious views of old man and woman, and other dialects scattered over the surface of European Russia, toinvestigate which was the object of Castrén's devoted exertions. It is much to be regretted for the sake of learning, as well as on other accounts, that he was snatched away before he had time to communicate to the world the results of his dauntless and ingenious labours.

CATALYST. [CATHYNT, S. J.]

CATAMACA, one of the upper provinces of the Argentine Central Division, was described by N. and N.E. by the province of Tucuman, E. by Santiago, S. by Cordova, and S.W. by L. Rioja, and comprehends the little visited country between the mountain ranges of the Sierra of Aconcagua and Ambato on the east, and the Andes on the west. The inhospitable country, in which there is neither soil nor water, is bounded by a principal valley, Catamarca, from which the province derives its name, and in which most of the inhabitants are settled; and of some other valleys, running between mountain ranges south-east and north-west, and terminating at their southern extremity on the borders of the Gran Salina, being thus separated from the other inhabited countries by high mountains and deserts. The rivers which water these valleys are lost in the Gran Salina. The climate is enjoy, especially when there is a south-east wind, called the 'Maiz.' Maize and wheat are raised to a considerable extent, but cannot be exported over the mountains. The province sends caiy cotton and red pepper (dried capucium) to the adjacent countries, the latter chiefly to Buenos Ayres, where it is extensively used in the preparation of the native drink 'Mate' or 'Chimango.'

Fernando del Valle de Catamarca, in 28° 28' S. lat., whose population is stated to be 4000. The first capital, called London, which was founded at the time when Philip II. of Spain married Queen Mary of England, was destroyed by an Indian insurrection.

CATHA, a genus of plants belonging to the natural order
Celastraceae. O. edulis is the Kat or Khalt of the Arabs. "It would appear," says Dr. Lindley, "to be of a stimulating character, and has been long esteemed by the Moors, who leaves with greediness, believing them to have the power of calming extreme watchfulness, so that a man may stand entry all night long without drowsiness. They also regard it as an antidote to the plague, and assert that a person wearing a twig of it in his bosom may go among the infected with impunity; they even believe that the plague cannot appear in places where the tree is cultivated." ('Vegetable Kingdom,' p. 867.) At the same time Forskail adds, "The taste of the leaves does not seem to do harm to the human body in such virtues." CATHARINE'S, ST. [CAMA, S. A.]

CATHCART, LIEUTENANT-GENERAL THE HON. SIR GEORGE, K.C.B., was born in London, on the 19th of July, 1814. He entered the 64th Foot, as a Second Lieutenant, in 1832, and was appointed Captain, in 1837. He was graduated Lieutenant-Colonel, in 1847, and Major-General, in 1857. He was married to Mary, daughter of William Shaw, the first Earl Cathcart. He was educated at Eton College, and entered the University of Edinburgh; and in 1810 he began his military life by joining the 2nd Life Guards. In 1818, by which time he had been promoted to a lieutenancy, he accompanied the expedition which also was sent to the semi-independent country of Russia. When thay arrived the French were already in possession of Moscow, and when the Emperor Alexander took the field in person in 1813, Lieutenant Cathcart joined the imperial army. He was with the grand army throughout the campaigns of 1813 and 1814, witnessed the battles of Lutzen and Bautzen, those of Dresden and Leipzig, of Brienne, Bar-sur-Aube, Arcis-sur-Aube, and the taking of Paris. Of these campaigns, and more particularly of the strategy of Napoleon I., as displayed in the battles, published a volume of Commentaries in 1860, from the facts collected during these campaigns, accompanied with diagrams showing the position of the armies, with their movements. It is a valuable work, additional interest being given to it by an introduction to the history of the powers of Europe, which constituted the French, and displaying the effects of national character under the different circumstances of attack and defence. In 1814 he again accompanied his sovereign to the field, who was one of the three plenipotentiaries sent to Vienna. On the return of Napoleon he was appointed aide-de-camp to the Duke of Wellington, and was present at Quatre Bras and Waterloo. He was in the appointment when the Duke became master-general of the Ordnance, and accompanied him on the mission to Aix-la-Chapelle, Verona, and Berlin. In 1828 he had arrived at the rank of Lieutenant-Colonel, and served for about eight years in Nova Scotia, Bermuda, and Jamaica. In 1834 he retired on half-pay; but in 1857 was recalled into active service on the outbreak of the outbreak in Canada, where he proved himself an active and efficient officer. After serving there for more than six years he returned home, and again retired on half-pay in 1844. In 1846 he was made Deputy-Lieutenant of the Tower, an office which he held till 1858, when he accepted the governorship of the Cape of Good Hope, with the command of the forces, and brought the Kaffir insurrection to a successful termination. On his return to England he was immediately sent as General of the troops over to Canada, as a mark of the confidence reposed in him by his profession. He however had short time to display his capabilities. In the battle of Inkermann, on the 5th of November 1854, where he displayed the most heroic bravery, a sabre wound made his eye so useless that he was rendered so superior that it failed in the desired effect, he fell, together with the other leading chiefs. He was buried on the spot—Cathcart's Hill—with 11 other officers who had fallen.

CATJULITE, a form of argillaceous mineral called Pipestone by the North American Indians. It comes from the Coteau des Prairies, and is a red claystone or compacted clay. A similar material is now accumulating on the north shore of Lake Superior, at Nepigon Bay. Another variety is used by the Indians of the north-west coast of America. (Dana, Mineralogy.)

CAT-MINT. [CATHYNT, S. A.]

CATH-A-EYE, a form of Chalcedony, of a greenish-gray colour, having a peculiar opalescence, or glaring internal reflections, like the eye of a cat; it is also called Ash-Tree Agate. It is a form of quartz in which the growths of asbestos come from Ceylon and Malabar, and possesses considerable value as a gem. (Dana, Mineralogy.)

CATHYNT, TAIL GRASS, the common name of Philonema semen, an agricultural plant, also called Timothy Grass. (Philom.)

CAUCHY, AUGUSTIN LOUIS, mathematician, was born at Paris, Aug. 21, 1789. His father, Louis François Cauchy, was a poet, and became archivist of the Chamber of Peers. The family was of old family stock. In 1804, while at the Ecoles Centrales, he was crowned by the Inquisite as the pupil who had carried off most prizes, among which was the first in Latin poetry. In the following year he entered the Ecole Polytechnique as second scholar,
and in 1806, when only in his seventeenth year, his solution of a difficult problem was printed in the 'Correspondance' of the school.

From the Ecole Polytechnique, where he rose to the first place, M. Cauchy entered that of the Ponts et Chaussées, maintaining the same position. He was afterwards appointed engineer of the works for the port of Cherbourg; the first time this date commences his long series of mathematical researches in questions previously unsolved. Among the first was his demonstration of Euler's celebrated theorem on the polyedra. In 1813 he published his 'Méthode pour déterminer les maxima et les minima des fonctions dérivées.' 'Extraction d'un dgré quelconque,' which was followed by papers on the properties of integrals, taking up questions started by Clairault. In 1816 he received the grand mathe-
nomical and physical prize, and the Institute for his paper 'Sur la Théorie des Intégrales,' which became the basis of a theory of light.

In 1816 Cauchy was elected as a member of the Academy of Sciences, and was appointed professor of mechanics in the Ecole Polytechnique, and in the same year he published his demonstration of Fermat's the-rems of the polygonal numbers. His lectures had a most salutary influence on the educational results of the school, and the progress of his pupils was materially aided by the works which he successively published as 'Leçons sur le Calcul Différentiel,' 1826; 'Leçons sur les Applications du Calcul Infinitésimal à la Géométrie,' 2 vols. 4to, 1826-28. At the same time he continued his valuable series of papers for the Annales des Sciences Mathématiques, which are labeled 'Sur les Limites Imaginaires,' 1826; 'Sur l'Application du Calcul des Residus à la Solution des Problèmes de Physique Mathématique,' 1827; 'Sur la Résolution d'Équations Numériques, et sur la Théorie de l'Elimination,' 1829; 'Sur la Théorie des Désordames,' and others. The last was presented in May 1830. The revolution which followed deprived M. Cauchy of his public employment, as his loyalty to the Bourbon dynasty prevented his taking the oath of allegiance to the government of Louis Philippe. Under these circumstances he accepted the post of Judge of the King of Sardinia, which invited him to deliver a course of physico-mathematical lectures at the university of Turin. In 1833 the Royal Society of London elected Cauchy one of its first foreign members. In the following year he received an invitation from Charles X. to undertake the scientific education of the Duc de Bordeaux, who then reigned at Prague; and he cheerfully devoted himself to the task. While thus engaged he resumed in 1835 the publication of the Annales des Sciences Mathématiques, which he had been for some years interrupted. In 1836 he published his 'Mémoire sur la Dispersion de la Lumière.' In 1838, having terminated his work of instruction, he returned to Paris and took an active part in the scholarly schemes for training a superior class of professors in the interests of science, of which he was destined to be a member of the bureau des Longitudes in 1839, but the minister refused to sanction the choice, remembering the refusal to take the oath of allegiance.

Cauchy's diligence appears to have increased with his years. The number and nature of his communications to the Academy may best be judged of by reference to the 'Comptes Rendus;' at one time they became so multiplied that their publication overstrained the Academy's funds. Concurrently he wrote papers which appeared in other scientific periodicals, chiefly in Liouville's 'Journal de Mathématiques,' among which his Note sur le Développement des Fonctions en Série ordonnées suivant les Puissances ascendantes des variables, published in 1841, is of great moment. In 1846 a professorship of mathematical astronomy has been created at the Faculty of Sciences of Paris, M. Cauchy was appointed to the chair; but, as had happened eighteen years before, his refusal to take the oath required in 1825 as a condition for his appointment, again compelled him to forego the advantages attaching to this post. As a recompense he was allowed to continue his studies; adding every month to the number of his works. He treated of the higher branches of algebra, the theory of numbers, the infinitesimal calculus, mechanics, astronomy, and many other sciences, explaining in fact every branch of mathematical analysis. Of him it was said that he mastered the entire domain of mathematics, and never exceeded the limits of the integral calculus; and if showing a preference for abstract questions, he on the other hand rendered important service to the elementary positions of science, by simplifying and strengthening them, as in all parts of geometry, and by giving a elegant demonstration of the fundamental theorem of the theory of equations.
Claudius is an exceedingly interesting book. At the opening of this book, the tunnel is about 20 feet high and 20 feet broad; but its course increases considerably as it advances through the mountains. Its whole length is three miles. It is in part cut through the solid limestone of Monte Salviano, and in part through a chalky earth that has little tenacity. Water for the latter substance occurs, but the former water is supported by a marble or marble-ware drain. To admit light and air the Romans sunk shafts from above. The entrance to this tunnel is about a mile and a half to the south of the town of Avezzano, on the west-north shore of the lake.

**CELIIDGE.** [Kildare.]

**Ceili.** The ultimate structure of animal and vegetable bodies consists of minute vessels, which are called Cells. In both cases there is the structure made up of a wall, generally visible to the naked eye, as they vary from the 1-50th to the 1-10000th part of an inch in diameter. In all cases they consist of an enclosing membrane or cell-wall, which includes in a space more or less enlaid within its constituents, called cell-contents. The nature of the substances which enter into the composition of the cell-walls and constitute the cell-contents, differs in the animal and vegetable kingdoms, but there are certain properties which all cells possess in common. Sometimes these properties are called by different names from those mentioned by the ancients for inorganic or mineral bodies, which are called physical. It will, however, be seen that independent of the formative power by which particles of gelatin, cellulose, etc., arrange themselves into cells and which inclose themselves into the forms of organs and beings of a specific form, there are few of the functions performed by cells which may not be referred to the action of physical forces. One of the first and most necessary conditions of the cell is that it has a passage or passage through which its walls are composed, of those substances by means of which it grows, and which it acts upon for the production of the peculiar secretions which characterise either specific beings or the organisation of their function. This function, which is called Assimilation, refers to the chemical relation existing between liquids and gases and the membranes of which the cell-wall is composed. [Assimilation.]

The liquid or gaseous contents which are thus introduced into the interior of cells undergo a variety of changes, according to the position, age, or other circumstances of the cell. Sometimes the fluid that is absorbed appears to be transmuted in compound structures from cill to cell without undergoing any great amount of change. In other cases, the materials are modified in such a manner that their properties are changed. The cells of some parts of vegetable structures are an instance of the latter, in which carbonic acid and ammonia are absorbed with water, and converted, either during their passage through the cell-wall, or whilst in the interior of the cell, into cellulose or the structure of the actin, the cell-wall of the cell. In other parts of plants the cells convey solutions of sugar and other substances without producing on them any change.

The constituents absorbed into the interior of the cell are the materials from which the cell-wall and all its contents are derived. The process by which the cell proper assimilates itself these matters is called Assimilation. This function is supposed to be carried on by an independent force or power residing in the cell, or some agent of cells, which form an organ or a body, and has been called the assimilative force or property, 'organising force,' 'organic force,' 'plastic force.' It is necessary in this process to separate between the chemical and the physical changes which occur, and which is probably the result of ordinary chemical forces under other circumstances, and the power or force by which these substances are made to assume definite forms in cells and organs. The latter is a specific force in the case of each cell, plant or animal changes take place in the elements introduced. The cells of some parts of vegetable structures are an instance of the latter, in which carbonic acid and ammonia are absorbed with water, and converted, either during their passage through the cell-wall, or whilst in the interior of the cell, into cellulose or the structure of the actin, the cell-wall of the cell. In other parts of plants the cells convey solutions of sugar and other substances without producing on them any change.

The result of the appropriation of the new matter absorbed from outside the cell is their enlargement or growth. This takes place in two ways: either the new matter is taken up into the interior of the substance of the cell-wall, which is always the case where the cell becomes augmented in size, or it is deposited in the form of layers in the interior of the cell-wall, but this is the first mode of growth is remote or irregular will be the form of the cell. The vegetable and animal kingdoms present almost all conceivable forms of cells from the spherical and hexagonal cells observed in the lower forms of plants, and the less organised tissues of animals, as cartilage, up to the elongated vessels of the plant, and the irregular cells of bone or vascular tissue in animals. The animal kingdom presents by far the greatest variety in this respect, and so great are the changes that some of the terms Metamorphoses or Transformations have been applied to these changes. As examples of these cells we may quote—the horny scales of the epidermis, of the hair and the nails, and the laminated pavement, epithelium—as white of the ovum, and the cell-wall is fused into one mass with the cell-content; the contractile fibre-cells of the smooth muscles; the tubules of the lens; the prisms of the enamel; the various forms of bone-cells; and the transmitting cells of the animal kingdom. All cells originate or are produced in the same way. Either they are developed free in vegetable or animal fluids, or they are produced in the interior of preceding cells.

In all cases they originate in connection with a substance called the nuclei, which exists in cells, either in the form of a small dark spot called a nucleus, or cytoplasm, in the interior of which is a nucleus, or of an expansion on the interior of the cell, when it is called the prismatic uricle. Free cell-development has been observed in other fluids about to undergo the fermentation process, and amongst animals in the chyle, blood, and lymph. The exact mode of the development of cells under these circumstances has not been accurately observed, and the cells under these circumstances are supposed to originate have not yet been proved to have had their origin independent of other cells. The most common form of cell-development is that in which the cell grows around or from the nucleus or prismatic uricle. In the animal kingdom development of cells can frequently be seen to take place around the nucleus, whilst in the vegetable kingdom its origin is more frequent from the folding in or contraction of the prismatic uricle upon itself, by which means two cells originate in one.

The development of cells around the nucleus and round the investing membrane, or prismatic uricle, within the walls of the cell, a multiplication of cells frequently takes place by division of the whole cell. This takes place in many of the lower forms of animals and plants [Pavert., S. 3], and also in the red blood-corpuscles of the embryos of birds and mammals, and in the coluires blood-corpuscles of the tadpole. It is probable that further observation will extend our knowledge of this mode of cell-development.

One of the highest problems for the physiology of the present day to solve is, the efficient causes of the phenomena of cell-development. The following propositions have been laid down by Kühne as an attempt to follow Bechmann's views as to the analogy between chemical changes in inorganic bodies and those which occur in cells:

1. The nucleus of the cell arises in the first place as a precipitate in an organisable fluid, and afterwards becomes consolidated in such a manner that a special investment of the contents with a nucleus appears. Its development may in this case be compared to that of inorganic precipitates, yet the constantly globular figure and size of the nuclei which are just formed, indicate some essential though not yet recognised condition peculiar to them.

2. In the development of cells by division the cell-nucleus plays exactly the same part which was previously ascribed to the nucleus, and the occurrence of the formation of cells in this manner is thrown into an analogy with chemical changes in inorganic bodies and those which occur in cells.

3. In cell-development around portions of contents, and in the cleavage process, the nuclei also operate as simple centres of attraction upon a certain mass of blastema, and then follow the separation of a membrane upon the uterus, into which mass, which is most simply understood as a condensation of the blastema.

4. In the cell-development directly around the nucleus the investment with blastema is wanting, and the nucleus develops directly into an intermediate mass. From what has been previously said, it will be seen that the cells are the active seat of the functions of both animals and plants, and the most conspicuous result of organisation may be described as the establishment of the cells to constitute the mass of the body, but by their agency alone all the special secretions and products of individual plants and
animals are formed. The food is conveyed into the body by
cells, the blood of animals is charged with cells, and the
material at the head is the nucleus of the cell and the
agency of cells. Nor are these last functions peculiar
to the animal kingdom. Contractility and sensibility seem to
be the property of the substance (protein) of which the nucleus
and plant, animal, and microbe are composed.

In 19th century it is thought that the historical
classification of animals by Linnaeus, which does nothing but
repetitively repeat itself; the other element, the periplasmic
substance (the cell membrane) being subject to all of the
chemical and morphological metamorphoses, in consequence of
which specific tissues arise. The differences between the
substances and the phenomena in the body of the
animal, and, as the prismatic urticaria, attains a large
cosmopolitan aspect; while in the animal the Endoplasm remains
small, the principal bulk of its tissues being formed by the
substance of the

This distinction however does not always hold good,
the Austrian furnishing examples of animals whose periplasmic
substance contains cellulose.

In 19th century, each plant is a stone, each stone is a
wooden case, and nature, like Sycorax, holds thousands of
delicate areas imprisoned within every oak. She is jealous of letting us
know this; and among the higher and more conspicuous
forms of plants reveals it only through obscure manifestations
which are required to certain principles inherent in the
Dinosaurs, or, still more slightly, by the phenomena of the
Cyclusis. But among the immense variety of creatures which
belong to the invisible world she allows more liberty to her
darlings; she is less scrupulous in the Fossil, and indeed all the
species are during one period of their existence as active
animals of a like grade in the scale. True, they are doomed
eventually to shut themselves up within their wooden cages and remain quiescent; but in this respect they are no worse
than the cell.

For further information on the subject of Cells, see the
articles Histology, S.I.; Cell, S.I.; Tissues, Organic, S.I. (Sharpey, in Quain's Elements of Anatomy; Köhler, Handbuch der Human Histology, translated for the Sydenham
Society by Huxley and Buck; Carpenter, Manual of Human

nal of Microscopical Science; and Transactions of Micro-
scopical Society, vol. 1.)

CENSUS OF 1831.

The Census of Great Britain in 1831
differed in several respects from any previous Census. In
some points the range of its inquiries was more minute and
precise; in many others wider and more comprehensive.
The character of the previous inquiries and the extent to
which they had been sufficiently indicated in former
volumes of the "Penny Cyclopaedia," here, therefore, before
giving some of the principal results of the Census, it will be
enough to state, in the words of the very elaborate Report
of the Registrar-General, prefixed to the volumes of Population
Tables, that the time of Parliament, what the Census of
1831 sought to accomplish:

"At the present Census it was resolved to exhibit not
merely the statistics, as before, of parishes, and, more com-
pletely, of parliamentary and municipal boroughs, but also
of such other large towns as England and Scotland and as
appeared sufficiently important for separate mention, and of all
the ecclesiastical districts and new ecclesiastical parishes
which, under the provisions of various Acts of Parliament
have, during the period under review, been ascertained or
eclesiastical districts. In addition also to the inquiry concerning
the occupation, age, and birthplace, of the population, it was
determined to ascertain the various relationships (such as
husband, wife, son, daughter)—the civil condition (married,
widowed, or child), and the number of persons
blind, or deaf and dumb. Further, under the impression
that the fifth section of the Act would authorize such
an inquiry, the design was formed of collecting statistics as to
women, by the assistance of the various religious bodies and
other places of public religious worship throughout the
country, and the number of persons generally frequenting
them; and also as to the existing educational establishments,
and the actual number of scholars under instruction. It was,
however, subsequently considered, on account of the rigid
construction of the Census Act rendered it compulsory
upon parties to afford information upon these particulars;
and the inquiry was therefore put aside as a purely voluntary
inquiry, open to the discretion of the城镇's registrars. At
former Census, any abstract of the parish registers for
the ten preceding years; the general system of registration
of births, deaths, and marriages, which had been for that
period in full operation, affording more complete and trust-
able information as to the changes in the population,
the Census was required to report to the Parliament the
populatio-

For obtaining these objects, the local machinery introduced
in England and Wales by the Poor Law and Registration
Acts was involved, and the general direction of the Census,
under the See of State, given to the Registrar-
General. The 684 Registration Di Lists, into which England
and Wales was divided by the Registration Act, each having
a superintendent registrar, are subdivided into 2150 B. di-
lists, and 3100 C. districts.

These districts were, for the purposes of the Census, and
under the superintendence of the registrars and superintendent-
registrars, again divided into 30,810 Enumeration Districts,
a
such district being assigned to one enumerator, who was
ordered to enumerate all the population of the
land, where no such local machinery existed, the Census
was taken in the course of the solicitors of counties and
chief officials of boroughs, the king of the Act being
required to appoint in each parish one or more
inhabitants, generally the parochial schoolmaster, in each
parish to divide it into convenient enumeration districts, and
superintend the proceedings of the Census thereon. The
number of enumeration districts formed throughout Scotland,
in 1831, was 9,641, and in the Isle of Man, 298, the
enumeration districts were similarly formed. Of the mode of
taking the Census, it will suffice to say, that blank-forms
were left at every house and public institution, with minute
directions, in order that they might be correctly filled up with
the requisite information concerning every person who was
in the house or apartment on the night of March 20, 1831.
These forms were collected by the enumerators on the 21st of
March; each enumerator being directed to satisfy himself,
and in no case as power of levying fines on the
conut that the returns were properly and accurately
inaccurate to correct them. The vast importance of
the method adopted, as a security for the accuracy and precision
of the returns, will be best understood by a comparison
with the method adopted in taking the Census of the United
States in 1820, and dated the 20th of October, 1820. The
States comprised an area of 3,300,000 square miles. To
number the inhabitants occupying that vast space the entire staff
of superior and subordinate officers employed numbered only
2260 persons, less than one-tenth of the number employed for
enumerating the population of England and Wales, a territory
of 48,320 square miles, or less than a fifty-sixth of the area
of the United States. It is at once evident that the American
census could not be made on one day, and accordingly
we find that though the schedules were directed to be filled
up with reference to a particular day, the officer did not
call at the house, the inmates of which were to be numbered,
till some days, weeks, or even months after the time specified;
when, on the contrary, in the Census of the British
States were required to come in advance of the Census, and
the returns were required to be furnished under the force of
law. On the whole, it is evident that the American
census could be made by the strength and careful appointment of
the official staff, and the strictness with which their duties
were defined, the arrangements for the Census of the British
States were in all respects admirable, and probably the returns
were made with a far greater accuracy and greater
trustworthiness. It may serve to show the amount of labour
which was involved in this army of enumerators (including Scotland,
particularly 39,000 in number), to state that the blank-forms for
England and Scotland were issued to the amount of 18,350,000,
and in all to nearly 7,000,000, the weight of them
being nearly 40 tons: the 'weight of the schedules, blank
enumeration books, and other forms, despatched from the central office, exceeded 25 tons.* The schedules, after being brought to London, were subjected to revision by the registers of the Customs, the Admiralty, and the Registrar of British Seamen; the enumeration of the army by the officers of the various branches, under the direction of the Commander-in-Chief. In these, as in other matters, the returns were much more accurate and regular than in the enumerations of the Census; while several collateral returns were at the same time obtained, such as of the latest population of the several colonies, the number of British subjects in various foreign states, the strength of the Indian army, navy, and marines, of Cheesemonger and Greenwich pensioners, of officers employed in the civil service of the Crown, &c.

We proceed now to the results of the enumeration of the population. The number of people in Great Britain, including the islands in the British seas, on March 31, 1851, was 20,959,477; and the men in the army, navy, and East India Company's service, abroad, on the passage out, or round the coast, belonging to Great Britain, on the same day, was 3,578,552. The total population of Great Britain, in May of the previous year, was 20,651,066. It was 318,369 females to every 100,000 males; in 1851 it was 103,363 females to 100,000 males. At both periods there were somewhat less than 30 men to 31 females. In 1851 there were 20 men at home to 31 females. The excess of births, however, is in the opposite direction. The 13 years (1839-51) in which accurate registers of births have been kept, there have been born 3,834,233 males and 3,163,029 females, or about 105 males to every 100 females (101,865 to 100,000). The disparity in the sexes at home is greatest in Scotland—110 females to 100 males; in England and Wales it is only 104 females to 100 males. To what degree the change in the proportions and the subsequent disparity of the numbers in the two sexes is due to emigration, or to a difference in degree of the dangers and diseases to which they are respectively exposed, this is not the place to consider.

The increase of population in the last half century nearly reached a new nation equal to that which existed in Great Britain at its commencement, and that notwithstanding the vast numbers who have "annually left the United Kingdom, settled and multiplied in millions in the United States, in the colonies of North America, of Australia, and of South Africa." The aggregate increase in the fifty years is 93.7 per cent., or at the rate of 1.299 per cent. annually. "The annual increase, however, has varied in each decennial period; it increased from 1.574 per cent. on the population in 1801-11, to 1.489 (nearest 1.49) in 1811-21, when it was at a maximum; the annual rate of increase in 1821-31 was 1.408; in 1831-41 it fell to 1.279; and in 1841-51 to 1.186 per cent. annually. The population therefore is increasing, but the rate of increase has diminished since 1821, caused by little emigration, and the mortality in England was lower than it has ever been before or since, down to the two last decennaries; when the public health has suffered from epidemics of influenza, cholera, and other diseases; while emigration from the United Kingdom has proceeded at an accelerated rate from 274,300 in 1821-31, to 718,000 in 1831-41, and 1,093,000 in 1841-51." During the same period the proportion of land to each person has decreased in Great Britain from 7,512 acres in 1801, to 6,972 acres in 1851; from 4 acres to 2 acres in England and Wales.

If the rate in which the population has increased since 1801 continued to prevail uniformly, the population would double itself in Great Britain every 52 years; in England and Wales, every 45 years.

The number of families in Great Britain in 1801 was 2,260,602; in 1851 it was 4,312,888; being an increase of 2,052,286. The families in England and Wales in 1801 were 1,856,733; in 1851 they were 3,712,880. In Scotland they were 394,078 in 1801, and 6,886,921 in 1851. The average number of families to a house in Great Britain in 1801 was 1:209; and of persons in a family, 4:645; in 1851 there were 1:182 families to a house, and 4:825 persons in a family. In Scotland in 1851 the average of persons in a family was 4:814; or more than the average of 4:645 in Great Britain. The average number of families in a house was somewhat higher—1:381. In Glasgow the number of families to a house is 5:4; of persons to a house, 2:75; Edinburgh the coro-pounding numbers are 4:2 and 20:6; in Aberdeen, 3:1 and 19; in Dundee, 3:2 and 10:7; and Perth, 2:9 and 12. In London, on the other hand, the numbers are only about the average of Scotland—1:74 and 7:7; but in some districts they are as high as 10, 11, and even 15 persons to a house. This excess in the northern cities was, in post of being the result of a natural increase of the population, the people. "The towns and cities of the two northern English counties and of Scotland are built in the continental style; and the families of the middle classes, as well as the poor, live in large flats, which constitute separate tenements." The term house, in many parts of Scotland, has been usually applied to these several flats or floors; and in every census from 1801 to 1841 "flats" in Glasgow and some other Scottish towns were returned as separate houses. In 1851 this was corrected, and the enumerators were instructed that flats and sets of chambers must not be returned as houses. The returns from Scotland, as from England, are now, therefore, made on a tolerably uniform principle, and are fairly available for comparison. The variations in the several English counties in the different districts (with respect to the proportion of families to houses, is considerable; but it would require far more space than we can spare to enter upon it. As a rule, in England and Wales, a house is inhabited by one family, the excess in the proportion being mainly caused by single persons, pensioners, hotel-lodging, &c. The following is an analysis of the families in connexion with the houses which they occupy in 14 subdivisions of England, containing 35,876 inhabited dwellings, in which the number of the houses (1,650 of the houses having the families absent), comprising 242,164 persons, or, on an average, nearly 7 persons to a house—5 to a family. Of these houses, 20,369 contained one family; 4,789, two families; 1,023, three; 745, four; 425, five; 224, six; 117, seven; 83, eight; 38, nine; and 28, ten families and upwards. This analysis is in the Report carried out with great minuteness into a variety of particulars, but which it is impossible for us here to follow.

The number of houses in Great Britain in 1851 was—
inhabited, 3,670,192; uninhabited, 166,735; building, 29,194. In 1801 there were 1,882,476 inhabited, and 67,330 uninhabited; the number building was not returned. The following tables show (1) the number of principal public institutions,—of the houses of officers and servants; and (2) the number of persons sleeping in barges, barns, tents, and vessels.

* "The enumeration of the houseless population, unsettled in families, is, however, necessarily imperfect; and the actual number must exceed the 15,849 returned, namely 9,972 in barns, and 5,877 in the open air. It is mentioned
in one instance that a tribe of gypies struck their tents and passed into another parish in order to escape enumeration. In 1841 the number of the houseless class was 23,303: owing to the more advanced period of the year (June 7) at which the Census was taken, many isolated people and labourers were then engaged in the hay harvest."

From houses and families we ascend to towns and corporations. No attempt was made to classify the smaller aggregations of houses by defining villages, hamlets, &c.; but 17,150 places were thus marked on the returns at a price or by a name, in the Population Tables, and each of these is assumed to be a village, or an aggregation of families round a church or chapel: on an average these villages lie at a distance of about 5 miles from the nearest town, or city, five hundred and eighty in England and Wales; two hundred and twenty-five in Scotland, and ten in the Channel Islands. To 21 of the preceding "villages" there is on an average a town, which stands in the midst of 110 square miles; central county towns was surrounded on 105 miles to the side, a circle having a radius of nearly 6 miles; so that the population of the country around is, on an average, about 4 miles from the centre."

"The population amounted to 31,566,856 in the 815 towns that were marked out in 1803, 3,154 miles of area. An average town of 19,623 inhabitants stands on an area of nearly 4 square miles; equivalent to a square of 2 miles to the side, a circle 1.5 miles to a radius; and the population is less than three miles from the centre."

"The population in the rest of Great Britain was 10,403,159; consequently if, for the sake of distinction, the detached houses, the villages, and small towns without markets, are called—country; at the present time the towns and country population, in the British Seas, they so little in numbers, that they may be considered equal, for by the abstracts 10,556,855 people live in the towns, and 10,403,159 in the country. In the towns there were 52 persons to an acre, in the country 53 acres to a person. The density in the towns stands at 13.5; in the towns—5,337 persons to a square mile."

"The 815 towns are grouped around 87 county towns—59 in England, 32 in Scotland, and 3 chief towns, equivalent to county towns, in the Islands of the British Seas. Each of the towns having an area from one to ten persons that can be considered as equal with the average of the British Seas; they were 35 miles apart. The population of the county towns of Great Britain, and the chief towns of the Channel Islands amounted to about 602,647 in 1801, and 1,359,583 in 1811; in England and Wales the population of the county towns was 1,65,647, and the total of all the lesser manufacturing towns—Sheffield, for instance, which is among the most important, stands 1,352, or only one eighth. As respects proximity of population, regarding it upon the same hypothesis of equal distribution, we find that the people of England were, in 1801, on an average 153 yards asunder; the mean distance was 106 yards asunder; the mean distance apart of the houses in 1801 being 362 yards, and 552 yards in 1811. Or, as it may be otherwise expressed, on the same area the population has doubled; the proximity has increased—the separation diminished. In the case of the small towns the proximity the mean the population increased from 918,635 to 2,362,236, being an increase of 1,403,373, or 146 per cent.; Manchester (with Salford) from 84,786 to 401,316; Liverpool from 82,285 to 376,955, its opposite neighbour Birkenhead rising in the same time from 110 to 24,285; Birmingham from 32,614 to 153,714, and from 15,174 to 69,884; Bradford from 13,364 to 103,778; Plymouth from 16,040 to 32,821; Southampton from 7,913 to 35,305; Merthyr Tydfil from 10,127 to 63,080; Glasgow from 77,058 to 329,007; and other manufacturing, mining, and sea-port towns, the (2) towns which are in mining districts, or are engaged in hardwood manufactures, and (3) the county towns, severally contributed more than three-quarters of a million to the increase; the increase of the people living in watering-places was 200,164. In the latter class the rate of increase was the smallest; Stockton in 1811, 25 per cent. annually. The annual rate of increase was 8,338 in the manufacturing towns, 2,336 in the mining and hardware towns, 2,191 in the sea-ports, 1,850 in London, and 1,089 in the county towns. The annual rate of increase in Great Britain during the period was 1,377. They have increased more rapidly in that which straw-plait, cotton, pottery, and iron are manufactured."

The density and proximity of the population are elucidated in the Report of the Commissioners in the Summary Tables in various ways, and at considerable length; here, however, we shall content ourselves in the Briefly. The density of population, or, as a recent French authority (Baron de Prony in the "Annaire") has proposed to term it, the "specific population," after the abstracts of the population of the districts of England and Wales, from 155,751 persons on a square mile in the East London district, to 18 on a square mile in that of Bellingham, Northumberland. The greatest density of population out of London is in the Liverpool district, which is 74,446, and the next Highest is its suburbs, which is 61,858 on a square mile. Manchester has 11,577, which is less than Leeds, which has 30,886; Bristol, which has 22,838; Plymouth, which has 20,441; Nottingham, which has 19,984; East Stonehouse, which has 19,015; Brighton, which has 18,088; Hull, which has 17,575; Sunderland, which has 11,507; Greenwich, which has 11,849; and Exeter, which has 11,617. The smaller density of Manchester than such towns as Salisbury and Exeter is accounted for, in a great measure, by the large number of factories and warehouses, the result is scarcely what would be generally expected, especially as both Exeter and Salisbury are cathedral towns, having considerable open spaces within the city boundaries. But the evidence of overcrowding in the large towns is manifest; where they are compared with some of the other most populous manufacturing towns: Sheffield, for instance, which is among the densest, has 6,663, or little more than half as many on a square mile as Salisbury. Bradford, which has 2,857, or less than one-fourth, and a third of which has 1,355, or only one eighth. As respects proximity of population, regarding it upon the same hypothesis of equal distribution, we find that the people of England were, in 1801, on an average 153 yards asunder; the mean distance was 106 yards asunder; the mean distance apart of the houses in 1801 being 362 yards, and 552 yards in 1811. Or, as it may be otherwise expressed, on the same area the population has doubled; the proximity has increased—the separation diminished. In the case of the small towns the proximity the mean the population increased from 918,635 to 14 yards in 1815. The Islands of the British Seas are noticed more fully in their respective Volumes than by previous Census. Five hundred islands and rocks have been described as follows:—Anglesley 57,316, Jersey 57,070, Isle of Man 63,344, Isle of Wight 50,284. Four others have each above Q
20,000 — Guernsey 29,757, Lewis 28,918, Skye 21,359, and Shetland 20,936. Two more number upwards of 10,000 — Orkney 16,665, and Islay 12,324. Twenty number between 1,000 and 10,000 inhabitants; fifteen between 500 and 1,000; three between a and 500; three between 100 and 500; forty-five between 10 and 60; seven number 10 inhabitants on each; and twenty-five under 10, two of them having only one inhabitant on each. Little Paps, one of the Shetlands, a woman, and Inshcolin, in Fifeashire, a man. Some of the small and smaller islands are now numbered for the first time, and much curious information has been collected. St. Kilda, one of the Hebrides, 70 miles from the mainland, is one of these. The population, now for the first time officially enumerated, consisted of 46 males and 62 females. In Ulster there were born, except one female, aged 35, who was imported from Sutherlandshire. The excess of females is chiefly among children under 20, of whom there were 22 males and 30 females; and persons above 60, of whom 6 are females and 1 is only a male. The men are all farmers and bird-catchers, each "farmer" occupying about three acres of land. Eight females are described as "weavers in wool." The great majority of children die as is called the "eight days' illness," several were born during the previous twelve months, but only two were living. There is a manse and a church on the island; but no resident clergyman or medical man.

The number of boroughs in England and Wales having municipal organization according to the Municipal Reform Act was 717; of which there were 4,245,269 in 1831, of which 18 have had charters of incorporation granted since the passing of that Act. There are 89 unrepresented boroughs. Of the reform districts boroughs it is found that one-half of the population (2,820,543) is contained in 17 boroughs, each of which contains more than 60,000 inhabitants. It appears also that 102 boroughs, or more than half of the total number, contain less than 9,000 inhabitants in each; in the aggregate, 472,551 inhabitants. Eighty-seven boroughs have from 2,000 to 7,000 inhabitants; twenty-seven, from 300 to 4,000; eight, from 400 to 6,000; seven, from 600 to 800; two, from 800 to 1,000; and three have 200 and upwards.

The 83 royal and municipal boroughs of Scotland contained 729,777 inhabitants; only three boroughs contained more than 60,000 inhabitants; one, more than 40,000; three, from 20,000 to 40,000; fifteen, from 7,000 to 20,000; thirty-three, from 2,000 to 7,000; and twenty-eight under 2,000 inhabitants.

Several of the most populous and important places in England and Wales are still without a municipal organization. Among these are the metropolitan parliamentary boroughs of the Tower Hamlets, population 539,111; Finsbury, 323,722; Marylebone, 370,557; Greenwich, 106,786; Lambeth, 251,345; and Westminster, 241,011; and the towns of Brighton, population, 69,673; Burnley, 20,809; Bury, 31,262; Chatham, 28,424; Cheltenham, 35,051; Dudley, 37,802; Huddersfield, 30,880; Merthyr Tydfil, 63,080; Rochdale, 29,168; Salford, 36,396; Wigan, 32,150; and Wrexham, 24,853. In Scotland there are not towns containing a population of 10,000 which are not municipal boroughs.

Additional abstracts, of a very valuable character, have been published subsequently to the General Report relating "to the ages, occupation, civil condition, and birth-places of the population; the numbers of the blind, and of the deaf and dumb; and the extent of the accommodation throughout the country for the purposes of education and religion;" but this is not the place to go into questions of so wide a nature. In another article will be found a notice of the Occupations of various Parish (p. 32) as exhibited in the Census returns.

With respect to Ireland, the circumstance brought out with most startling prominence was the remarkable decrease in the population since the previous Census. Up to that of 1841, each decennial Census of the half-century had shown a steady if not rapid increase of the population. That of 1841 showed that during the past ten years the gain of the previous twenty had been more than undone. In 1821 the total population of Ireland was 6,601,827; in 1831 it was only 6,551,970. And the returns further showed that this decrease was not confined to any one single county, but as compared with 1821, the only exceptions were some two or three places in Ulster, in each of which, from causes easily understood, there had been a continuous increase of inhabitants during the half century. The large falling-off of the population between 1841 and 1861 was mainly owing to the disastrous famine which afflicted Ireland in 1845-47, in consequence of the failure of the potato crop; partly, however, it was due to emigration, which, in its turn, had been greatly stimulated by the failure of the potato, and the consequent agricultural distress. The total emigration from Ireland during the ten years between 1841 and 1851 is estimated to have amounted to 1,389,133, "varying with considerable regularity according to the variations in the state of the labouring classes." For the purpose of presenting in one view the increase and decrease of the population of Ireland, we append a table of the number of inhabitants in the four provinces at each decennial Census from 1831 to 1851.

</table>

The decrease of population was as might be expected most marked in the rural districts. In several of the large towns the Census of 1851 showed an actual increase of population, while scarce any showing a falling off, a circumstance arising no doubt from the farming poor having crowded into them in the hope of obtaining employment or of finding relief. Dublin city, which in 1831 contained 185,881 inhabitants, had 258,788 in 1841, and 296,361 in 1851. Cork, though it showed a decline of nearly 15,000 between 1821 and 1851, showed an increase of above a thousand from 1841. Belfast had more than doubled in population between 1821 and 1851, and between 1851 and 1861 had increased from 75,308 to 100,300. Galway town, which between 1831 and 1841 had fallen in population from 33,190 to 17,975 had increased in 1851 to 23,665.

The two following tables will show in the readiest manner the general results of the enumeration of 1851.

| Area, Houses, and Population, on March 31st, 1851. |
|-----|-----|-----|-----|
| Great Britain and the British Seas | 57,924,577 | 3,670,122 | 166,753 | 29,194 |
| England and Wales | 37,324,915 | 3,275,039 | 153,494 | 26,751 |
| Scotland | 20,047,662 | 370,308 | 12,146 | 2,429 |
| Islands in the British Seas | 292,900 | 21,945 | 1,005 | 203 |

Total | 20,057,497 | 3,275,039 | 153,494 | 26,751 |

The decrease of population as might be expected most marked in the rural districts. In several of the large towns the Census of 1851 showed an actual increase of population, while scarce any showing a falling off, a circumstance arising no doubt from the farming poor having crowded into them in the hope of obtaining employment or of finding relief.

| Great Britain and Islands in Brit.

### In the article Great Britain of the 'Penny Cyclopædia' a table is given of the population of the counties of England, Wales, and Scotland, with the areas in square miles, according to the Census of 1831, and under the head Ireland a similar table is given for that island. In the former Supplement, under the head Census, tables are given of the population of the counties of Great Britain and Ireland, according to the Census of 1841. We now give tables of the population of Great Britain and Ireland, with the areas in acres, according to the Census of 1851, followed by a list of towns in Great Britain and Ireland, arranged under their respective counties, with the population of each in 1851.

### Q2
In the following list, the towns generally contain a population of 2000 and upwards, but several are also inserted which have a smaller population. The Parliamentary Boundaries placed first; then follows the list of the towns, including the parliamentary boroughs, which are in many instances also Municipal Boroughs, having a population different from that of the Parliamentary Boroughs. The Burghs and Contributory Burghs of Scotland are arranged under their respective counties, but a list of the Parliamentary Districts of Burghs is given at the end of the list for Scotland. The abbreviation P.B. signifies Parliamentary Borough; C.P.B., Contributory Parliamentary Borough; M.B., Municipal Borough, and includes the Scotch Royal Burghs. Sometimes P. and T. are inserted in the figure-column, and signify Parish and Township, where the returns of the census do not state the population of the town itself.

CENTROUS (Illiger), a genus of birds belonging to the order Anseriformes. The species are natives of India and New Guinea. They have a long pointed beak, like the more common ducklings and storks. Their plumage is rigid and spinous. They build their nests in the holes of trees, and lay white eggs. They feed chiefly on grasshoppers, and dwet amongst roots and other herbage, and do not often take to water. Their flesh is not pleasant eating.

CERADIA, a genus of plants belonging to the Compositae family of the order Compositae. C. furcata is a half-succulent plant, inhabiting the most sterile regions of Africa. It yields a soapy substance, which gives off a fragrant odour when burnt, and has been called African Balsam; it is

DigiByte®

Digitized by Google
however a very different thing from the true Bellidium.

**BELLIDIIUM**

**CEREBUS** a genus of plants belonging to the natural order Cereales.

It is characterized by its sepals being very numerous, imbricate, adnate to the base of the ovary, united into an elongated tube, outer ones shorter and like a calyx, middle ones longer and coloured, innermost ones petaloid; the receptacle is globular or oblong, tuberous, or oval from the remains of the sepals. The species are feebly grotesque shrubs, with a woody axis and soft interior. They possess angles which are vertical and covered with bodies of spines. The flowers are large, arising from the angle to the base of the leaf. The Old Man Torch-Thistle, *C. emilii*, is an erect plant, bearing a stem with 25-35 vertical ribs, covered with fascicles of bristles, each fascicle containing from 15-20 radiating bossed-curved bristles. Its long grey bristles give it the appearance of the head of an old grey-haired man. It is a native of Mexico.

**C. flagelliformis,** the Creeping Cereus, has prostrate stems with about 10 angles. It is very common in our gardens, and its trailing stems require the support of trellis-work. It bears an abundance of beautiful red and pink flowers. It is a native of South America, though now naturalised in Asia and Africa.

**C. grandiflorum**, the Night-Flowering Cereus, has naked stems with 5 or 6 angles and fascicles of bifi-tips, with the ribs such fascicles. It is a native of the West Indies, and is found in many parts of the mainland of South America. This plant when cultivated produces very large beautiful sweet-scented flowers. They are also very fragrant, and flower most of the time from April to November, and last for three or six hours. They generally begin to open between seven and eight o'clock in the evening, and are fully expanded by eleven or twelve, and before the next morning they are quite faded.

**C. goniocarpa** is an erect plant, 3 or 4 angled, the angles toothed, the prickles subulate, straight, rising from a white tomentum. It is a native of Mexico, but is very commonly cultivated in our gardens, on account of its large flowers, which are of a beautiful scarlet, the inner petals having a triquetrical character, was called the 'Bluebell of the Desert'. The various species of plants have been described, and a fine collection of them exists in the Royal Gardens at Kew. They are of easy culture, and require the same general treatment as the order to which they belong. [Cactus].

**CERES ABBAS.** [Douglasiana.]

**CERNA,** a genus of fishes belonging to the section Lanthidermidae and the family Percida. It includes the Ruff or Pope, a British fish, which has also been named *Lanthiderma Lanthina.* The arrows of *Lanthiderma Ctenosoma,* as given by Yarrell in his 'British Fishes,' is as follows:--'Dorsal fin single, elongated, the rays of the fin portion spines, the others flexible; branchiostegous rays seven; teeth very small, uniform, numerous; head without a single jaw tooth to the pre-operculum indented; spiracle ending in a single point.'

In *Acronia vulgaris,* the Ruff or Pope, the prevailing color of the upper part of the body and head is a light slate-brown, passing into a yellowish-brown on the sides, and becoming almost silvery-white on the belly. The lateral line prominently and strongly marked. Small brown spots are disseminated over the back, dorsal fin, and tail, assuming on the latter, from their arrangement, the appearance of bars; prismatic, central, and anal fins, pale-brown. This fish is an inhabitant of fresh waters, and closely allied to the perch. It was first described by Dr. Caius, who named it *Apsara,* being a translation of our word 'Ruff' (rough), which is applied to this fish by account of the hair-like texture of its denuded scales. It is found in all the rivers of England, specially the Thames, the Isis, and Cam, and is found in the colder parts of the European continent. It is like the perch in its habits. (Yarrell, *British Fishes.*)

**CERES BONNORUM.**

The proceedings of the trustees in *Ceres* have been subjected to the control of the Court, and its bankrupt, in Bankruptcy, in the same way as those of Bankruptcy. When a bankrupt's assets do not exceed 100L, he is entitled only to the advantages of the judgment in a *Cessio* (10 & 20 Vict. c. 79).**

**CHALCEDON.** [Astrak.]

**CHALCIS,** the ancient name of the town of Erypous.

**CERDAZ.**

**CHALK FORMATION.** [Cretaceous Group.]

**CHALMERS,** the REV. DR. THOMAS, was born at Anstruther, in Fife, on the 23rd of March 1670. He was the sixth child of a family of fourteen, born to Mr. John Chalmers, a dyer, shipowner, and general merchant in Anstruther, by his wife Elizabeth Hall. Educated first at the parish school of Anstruther, and next at the University of St. Andrews, he was early distinguished as an uncommon reader—less however in the formal business of the classes, than in his general intercourse with his fellow-students. Having chosen the clerical profession, and gone through the usual theological studies at St. Andrews, he obtained, with much ease, a licence in 1707 to preach. This licence was purchased by him in Edinburgh, where he occupied himself in teaching, and also in attaining the classes of Dugald Stewart, Robison, Playfair, and Hope, then in the height of their fame. It was at this time that his passion for mathematical and natural philosophy, as an additional study, acquired an original speculation on moral and social subjects, first conspicuously revealed themselves. After a period of desultory occupation, first as assistant to the clergyman of Carsers in Roxburghshire, and then as assistant to the mathematical professor of St. Andrews, he was admitted to the benefice of Kilmany, in his native county of Fife; into which parish he was inducted on the 12th of May 1803. He was then twenty-three years of age, and he continued in the position of a minister and professor of mathematics at Kilmany until 1815. These twelve years formed a very eventful period in his mental history. On adopting the clerical profession he had brought into it no very decided views in doctrinal theology. He was attached to what was called the 'Moderate,' as distinct from what was called the 'Reformed.' The Moderate was called the 'Younger Scotch,' and the Reformed was called the 'Older Scotch.' He was of opinion too, that by devoting a day or two each week to the preparation of his sermons and to official clerical acts, a clergyman could amply discharge all his proper duties, so as to have the rest of his time at his disposal, whatever other occupations interested him. He carried this view into practice. During the first year of his incumbency he varied his professional work at Kilmany by courses of lectures on mathematics and chemistry at St. Andrews. His chief reference at this time was to the *Planetary Tables,* the one of grandeur of the world, and for natural science over theology was indicated by his being candidate in 1804 for the chair of Natural Philosophy at St. Andrews. With even less chance of success he offered himself in the following year as a candidate for the mathematical chair in Edinburgh. The mathematical chair in Edinburgh, which was created in 1696, and to which Playfair was appointed, and which was held by Sir John Leslie, obtained the post, and it was with reference to an argument in Leslie's favour urged at the time by Playfair, to the effect that "the vigorous prosecution of mathematical or natural science was incompatible with clerical duties and habits" that Mr. Chalmers made his first literary appearance. In reply to Playfair he published an anonymous pamphlet, vehemently defending the clergy against what he regarded as a "cruel and libellous inscription"—a pamphlet, the main tenor of which, if not its specific statements, he lived to disown. His next publication was in 1807, when, his thoughts on political economy being considered a result of receiving a stimulus from the agitation caused by Napoleon's decrees against British commerce, he issued a pamphlet, entitled "Inquiry into the Extent and Stability of National Resources." This publication had success sufficient to inspire him for a time with the idea of coming to London to increase his literary connections. Circumstances preceding him from realising this idea, he continued at Kilmany, with a growing reputation for various attainments, as well as for extraordinary energy, accompanied with some eccentricity, of character. He made his last speech in the General Assembly of the Scottish Church in the last of many of his oratorical triumphs in after life. In the same year he became a contributor to the *Edinburgh Encyclopaedia,* under the editorship of Dr. Brewster, now Sir David; and it was partly to his studies while preparing an article on "Christianity" for that work, and partly to the solemnising
effects of a severe illness which, during the winter of 1803-4 bore him so heavily, that extraordinary powers attributed the great moral and spiritual effect of his life. Then, for the first time, as he thought, he saw Christianity in its true light; and then for the first time also was he of the duties of the clerical office, as he thought, sufficiently deepened to enable him to perform them. It is now generally true that we have a clearer idea of this, whereas hitherto he had belonged to the 'Moderate' party in the Scotch Church than in the majority, he now ranked with the 'Evangelical' party, which formed but a minority. But the fruits of the change were more immediately visible in his own conduct, and in the communings of his mind. It was generally observed that in all that Mr. Chalmers did the influence of a deep sense of religion, and a conviction of the paramount claims of Christ upon the thoughts of men, were discernible. Always eloquent in the pulpit, his eloquence now burst forth in strains of such passion and fervour as had never been heard from him before; and from far and near people went to hear the wonderful minister of Kilmany. Bible and missionary societies, for which he had formerly cared, he now supported with increased zeal. In the spirit of his new principles he transferred instead of confining his ministerial studies to his weekly sermons from the pulpit, he began a regular organisation of his parish with a view to make himself familiar with the interests of every individual in it, and to provide for all its spiritual wants and needs; and this spirit was in him amidst all these new occupations, which he prosecuted with his constitutional enthusiasm, he married, in 1812, Miss Grace Pratt, the daughter of a retired captain in the army. In 1813, on his return from a tour in the Southern United States, appeared in the 'Edinburgh Encyclopedia,' and in the same year it was published, with additions, in a separate volume as a treatise on 'The Evidences of Christianity.' The following two years were spent in industrious parochial work, in theological study, and in the composition of miscellaneous works on various topics, including one on the reconciliation of scripture and geology.

The name of Mr. Chalmers was pretty well known over the south of Scotland as that of a man of powerful mind and extraordinary eloquence when, in 1815, or in the thirty-sixth year of his age, he was called from his quiet parish to assume the pastoral care of Tron parish in the city of Glasgow. He remained in Glasgow all the years. In 1816 the degree of D.D. was conferred on him by the University of Glasgow. From 1815 to 1819 he was minister of Tron parish. From 1819 to 1823 he was minister of the newly-constituted parish of St. John's. These eight years formed the period of his highest celebrity as a pulpit orator. In this city he达到了 the highest pitch of his pulpit oratorical power; and on his occasional visits to Edinburgh, London, and other places, his name as an orator preceded him, and drew crowds to hear him at. At Edinburgh his oratory was exhibited not only in the pulpit, but also in the debate, where he was bold and active in the discussion of the political questions of the day, and his oratory was a formidable and irresistible weapon. His speeches, like his sermons, were generally read; and very rarely indeed did he speak extemporaneously. With all his extraordinary popularity as an orator, however, no man appreciated his Doctrinal Sermons upon the Church and the Christian Orator,
S. Andrews and in the neighbourhood round; annually in May he visited Edinburgh to take part in the business of the General Assembly, where his eloquence as before was felt as a co-operating force on the "Evangelical side" of all the great sessions, and where, from the very commencement, and for the whole tenor of his future career, was not carried out. The literary results of his five years' sojourn at St. Andrews were the volumes of "Lectures on Moral Philosophy," and "Political Economy," prepared for his class and reserved for publication; the "Liberties and Grievances of Toros," published in 1826; and a treatise on "Ecclesiastical and Literary Endowments," published in 1837.

Dr. Chalmers' next appointment was to the chair of Divinity in the University of Edinburgh. The duties of this office he assumed in 1828, and he discharged them during fifteen years—i. e. from 1828 to 1843, or from his forty-ninth to his sixty-third year. His activity during these fifteen extraordinary years of his life (not taking account of his occasional sermons) was made up of three distinct kinds of work—his duties as theological professor; his continued exercises in literature, speculation, and schemes of Christian philanthropy; and his controversial energy in connection with the ecclesiastical struggle which during that time agitated Scotland.

1. His Moral or "Political" Professor. —In this important capacity, which involved the theological instruction and training of between one and two hundred young men annually for the Scottish Church, Dr. Chalmers exerted a remarkable influence. In the new church he saw himself as a man of noble purpose and burning enthusiasm, with whom no young man could come in contact without love and reverence, and who was in the habit not only of communicating massive thoughts of his own on almost all subjects, his ideas of stirring up thought among others; but who was truly a centre of life and intellectual influence; and those who went forth from it carried with them the performance of his spirit and many of his views.

2. His independent labourers. —Churchmen, in whatever capacity, whether it is possible to take full account; suffice it to say that in 1831 he published his treatise on "Political Economy," and in 1833 his Bridgewater treatise on "The Adaptation of External Nature to the Moral and Intellectual Constitution of Man," that in 1838 he delivered in London, and afterwards published, a series of "Lectures in Defence of Church Establishments." That in the following year he made a tour through Scotland to advocate the cause of church extension; that in 1840 he published his book on "The Church and the Parochial System Without a Poor-Rate for the Right Management of the Poor," that during the same period he delivered, during the summer vacations various lectures to popular audiences on topics of natural science; and that he gave some sign of his daughters, one of whom married a man under whose superintendence a new issue of the collected works of Dr. Chalmers has been put forth in twenty-five volumes, and who has also written his life in four volumes, and edited much of his correspondence.

Dr. Chalmers was a man of powerful frame, not tall, but massively built; his head was very large. It was remarkable in a man so celebrated over Britain as an orator, that he always spoke not only in a broad Scottish, but also in a broad provincial accent, which is almost every word. Personally he was a man of most simple, bland, and sociable manners, with a great fund of anecdote and broad humour. His works, notwithstanding the force of intellect that they show (and his speculations in social and political economy, in particular, are used by many of the best thinkers of the day who have no sympathy with his theological or ecclesiastical opinions), but faintly convey an idea of what the man was while alive, and of what he still is in the mind. It is therefore found that they are printed in small volumes, and that the whole tenor of his life was expressed, in the words of his friend, "of healing the breach which had been made, and restoring quiet to Scotland; but at last, these hopes being over, the struggle was ended at the meeting of the General Assembly on the 18th of May 1848, by the so-called 'Disruption,' i.e. by the voluntary secession of upwards of 400 clergymen, followed by a large portion of the people of Scotland from the Established Church, and the institution of a new ecclesiastical body called 'The Free Church.' At the head of this secession was Dr. Chalmers, who was nominated moderator of the first General Assembly of the new church.

The last four years of Dr. Chalmers' life were spent by him as Principal and Professor of Divinity in the New College founded by the adherents of the Free Church for the theological education of young men (the University of Edinburgh having been necessarily vacated by him on his secession from the establishment). During these years, too, he exerted himself prodigiously in arranging the organisation and raising funds for the new church, and even, probably at no period of his life was the statesman-like character of his intellect, his power of dealing with new social emergencies, and of leading men, more conspicuously shown. He had seen the foundations of the new church laid very much to his mind, and was about to complete the work of completing its organisation into the hands of his many able and younger colleagues, and to devote the rest of his days to his labours as a theological professor, to Christian charity in connexion with the life of the Free Church, with the 'North British Review,' then started under his superintendence, and to a new experiment of Christian philanthropy which he had begun in one of the most wretched quarters of the old town of Edinburgh, when death removed him. He had just returned from a visit to England in apparently excellent health and spirits, to take part in the proceedings of the General Assembly of the Free Church, when on the morning of the 31st of May, 1847, he was found dead at his lodgings at Margaret Street, near Edinburgh. His death was felt throughout Scotland like a national calamity; and all ranks and parties joined in doing honour to his memory as one of the greatest men that Scotland had produced. He left a widow who did not survive long, and six children, four of whom married, one of whom married under whose superintendence a new issue of the collected works of Dr. Chalmers has been put forth in twenty-five volumes, and who has also written his life in four volumes, and edited much of his correspondence.
them. They have the fragrance of Myrrhstone. Fifteen genera and fifty species are included in this order, all natives of Australia. Their position, according to Lindley, is between Astrangies and Myrtaceae, near to Myrtaceous. (Lindley, Vegetable Kingdom.)

CHANCERY, COURT OF. There are now three Vice-Chancellors (6 Vict. c. 5; 15 Vict. c. 4), before whom and the Master of the Rolls all suits in this Court are originally heard. The Court consists of two justices, one of whom is the Master of the Rolls, and the other a justice of the court, the justices being agreed to by the Lord Chancellor and the Chief Justice of England. The master is appointed in council from among the whole delay which has always been the standing reproach of this Court was thought to rest, have been abolished, their functions being now performed by the Master of the Rolls and by the joint solicitors of the court.

CHAUDINNE, Chaotic Plants, a family invented by Bory, for the purpose of placing a number of the lower forms of plants or organic beings of uncertain character, which could not be placed among other families or groups of Cryptogamia. To this family were at one time assigned forms of Distotinae, Desmidoth, Nostoc, and others.

CHAR, or CHARR, one of the British species of the genus Salmo, of the Salmon tribe (Salmo salarines)...

CHARITIES. [Usas, S. 2; Tawne, S. 2.] By the Charitable Trusts Act 1833, a body of commissioners has been created for England and Wales, with power to inquire into all charities, their nature, objects, and administrations, and the condition of the property belonging to them; to report upon the production of accounts and documents from the Trustees of Charities, and to cause inspectors to visit and report on their management. No proceeding with reference to any charity can be taken unless the inspector has reported without the consent of the Persons responsible for this which is called 'The Charity Commissioners for England and Wales.' The Attorney-General alone may proceed by ex officio information. The board may direct in what court proceedings for the administration of any charity are to be taken; but where the income is under 30l., the County Court of the district, or the County Court of Bankruptcy of the district in which the charity is situated has jurisdiction. In other cases the court of Chancery must be resorted to. The commissioners may extend to the Universities, or the City of London. A report of the proceedings of the board must be annually laid before Parliament.

DAVID HENRY, BARON, the resolute defender of Antwerp, was born at Thiel, in Gueldre, March 18, 1765. In 1775, he entered the Dutch army as a cadet, but he left that service after the revolution in Holland in 1787, and attached himself to the French army, in which he continued for many years. He became a lieutenant-colonel in 1793. In the fierce war with Prussia in 1806, he greatly distinguished himself under the Dutch general Dumouriez, and was made general of brigade. He afterwards took part in the Peninsular War, and displayed so much intrepidity that the soldiers nicknamed him General Bayonne, from his constant use of that weapon. In 1811 Napoleon created him a baron of the empire. He was frequently wounded, and during the campaigns of 1813 and 1814 he had several horses killed under him. He fought likewise at Wavre, in 1815. Soon after the peace he was made governor of Antwerp, and his admirable defence of the citadel in 1832, with a garrison of 6,000 troops, against an army of 76,000 French soldiers commanded by Marshal Gérard, attracted general attention throughout Europe. Bayonne made the brave old soldier very popular. He died on the 2d of May 1846. (Biog. des Contemporaines; Campo, Life of Chaste.)

CHATEAUBRIAND, FRANÇOIS-RÉNÉ, VISCOUNT D' OAKES. The French writer, who was born at St. Malo on September 4th, 1768, being the youngest of ten children. He was at first intended for the church, but after a careful education for that calling, he entered the army as sub-lieutenant in 1786. After various adventures he appears to have visited Paris shortly before the Revolution, and to have witnessed the capture of the Bastille in 1789. His erratic disposition took him to America in 1791, to look for the North-West Passage. He spent several months in the States, had an interview with Washington, and, after falling in love with the Virginian forest and wild scenes of primitive life which he has described so vividly in 'Rêve' and 'Atala.'

On his return home he joined the army of Condé for a short time in 1792, and the next year he began a life of great comfort and ease. He then drifted about the northern parts of France, and lived in the society of the nobles, equally wretched. The picture of his sufferings and privations at this time, as he relates them in his 'Mémoires,' is almost incredible. Nevertheless he continued in England nearly eight years, and maintained himself by translating for the Morning Post, giving lessons in French and Latin. In 1797 he published in London his 'Essay on Revolutions,' a work full of scepticism: but the death of his mother in 1798 gave a new turn to his thoughts, and restored his faith.

In 1799 he married the daughter of a Mr. Fontane, whose influence was already strong, and who had been appointed one of the editors of the 'Mémoires,' in the columns of which 'Atala' appeared for the first time. This romance was followed by the 'Histoire de Christiane' in 1809, which made a deep impression on the public mind. The First Consul was so pleased with this work that he took the author into favour, and strove to bend him to his service by two successive appointments. Unfortunately the execution of these schemes could not make the writer sufficiently anterior with the new government to furnish the inflexible Breton with just too an excuse, and he resigned his appointment the same day. Fontane, Madame Bacceochi, and even Josephine herself, could scarcely prevent the consequences of this rash act from falling on the 'Soldat.'

The reign of Napoleon, which lasted ten years (1804-14) was not favourable to literature, and during this period Chateaubriand produced nothing of note, save the 'Martyres' in 1807, and 'Histoire & Jerusalem' in 1811: the latter was the account of his own visit to the Holy Land in the autumn of 1806. The fall of the empire in 1814 released his pen, and he produced his famous pamphlet, 'De Bonaparte et des Bourbons,' the influence of which in disposing the people of France to the return of the Bourbons was powerful, that, "it was equal," said Louis XVIII., "to an army of 100,000 men." The Viscoun was now received with great favour at the Tuileries, but he refused office as a colleague with Fouché; and other circumstances delayed his entrance into public life until 1817, when he was sent as ambassador to the British court, and most honourably greeted by all classes of people. The next year he was appointed Minister of Foreign Affairs, an office he held during the first three years of the new empire. In 1818 his son was given him the embassy to Rome; but no sooner had the Polignac ministry been formed (August 8) than he resigned.

In 1828, after the fall of the monarchy, which he had assisted to destroy, this inexplicable man, whose people claimed as their leader, and followed with acclamations, deliberately resigned his titles, his offices, his very means of subsistence, to rally to that cause which had no other supporter. A singular change came over his spirit; he sank into a religious retired career, which deprived him not only of the world, but, perhaps, of the most perfect happiness. He studied the 'Mémoires d'Outre Tombe'—the reading of which is most painful. He died July 4, 1848. His character has been well summed up by a recent French writer:—"It was almost invariably the fate of M. de Chateaubriant to lead a double life: nature or duty, art or reality. Sometimes he was at the same time a hero and a villain, a saint and a rascal; at the same time a great man and a public character. At the very time he was crushing his adversaries, he had no influence over his friends."

(Mémoires d'Outre Tombe; Biographie Universelle; Dict. de la Biographie Universelle.)

CHATHAM. [Canada, S. 3.]

CHEMISTRY. Although the original articles on Chemistry in the 'Penny Cyclopaedia' were written up to the time they were produced, the progress of this science was so rapid that a large addition was made to them in the first supplement, and a further large volume in that work, under the head of Chemistry. In this
second supplement an addition of the like kind was found necessary, and the same plan has been pursued of adding the additional matter in an alphabetical form.

In the original articles in the "Penny Cyclopaedia" it was not thought necessary to represent the various compounds by means of symbols. The study of the science is however so much facilitated by the use of symbols, and the progress of organic chemistry so comparatively so far from intelligible without them, that we here subjoin a list of symbols most commonly used by the chemists of this country and the continent. To each of the symbols there is also added the equivalent or atomic number, an explanation of which will be found in the "Penny Cyclopaedia" article Aromatic Compounds.

</table>

In the following articles the number of atoms of each element in a compound body is added. In order to ascertain the relative weight of any element in a compound, the number of atoms of each must be multiplied by its equivalent weight, and thus the quantity of each element in a given weight of a compound may be ascertained. Most of the references relate to other names, given in the present article; where they refer to previous articles in the "Penny Cyclopaedia", P. C. is added.
However, to the inorganic as to the organic acids. It is very
obvious that the compound $\text{SO}_4^2- + \text{H}_2\text{O}$ may be arranged as
$\text{SO}_4^2- + \text{H}^+$, and that such a change may be effected in the ex-
pression of any of the acids. In this view of the com-
position of the acids, the hydrogen, not the water, is the re-
moveable element; and it would appear from experimental results, that the reaction on the oxygen of acids is
theory is more compatible with the real condition of the
acids than the first. This constitution is as easily applied
to the organic acids as the other. Thus, instead of the above
formula, we have the following:

- Sulfuric acid, $\text{SO}_4^2- + \text{H}^+$.
- Acetic acid ($\text{CH}_3\text{CO}_2\text{H}$) $\text{O}^+ + \text{H}^+$.

It has been objected to this theory that it assumes the
existence of compound radicals which have not been demon-
istic process, which we believe are only hypo-
thesis have now been separated, and no argument against
the theory can be successfully urged on this ground.
The advantage of this theory is, that the formation of salts
is easily explained, on the supposition that the metal replaces
the hydrogen of the acid. Thus, in the first system, sulphate
of soda was formulated as $\text{SO}_4^2- \text{Na}_2\text{O}$, and no account
was taken of the water lost by the sulphuric acid. But under the
new theory the oxygen of the metal needs not to be taken
into the formation, as it is already present in the sulphuric acid,
and the change from sulphuric acid to sulphate of soda is seen as follows:

Sulfuric acid, $\text{SO}_4^2- + \text{H}^+
Sulphate of soda, $\text{Na}_2\text{SO}_4$.

The sodium atom is in the place of the hydrogen.

In the constitution of the polybasic acids this theory is
more strongly confirmed. Thus phosphoric acid was sup-
posed to assume three forms, according as it united with one,
two, or three atoms of water, and these were called mono-
hydrated, bihydrated, and terhydrated acids. But Professor
Graham showed that it would be better to regard these acids
as combined with one, two, and three atoms of hydrogen,
and proved that the phosphoric acid in its three forms united
with metals by their taking up the place of the hydrogen of
the acid.

That the old formulas for the organic acids may be easily
reduced to the new is seen in the following examples:

- Tartaric acid, $\text{C}_4\text{H}_6\text{O}_4 + 2\text{H}_2\text{O}$.
- Malic acid, $\text{C}_4\text{H}_6\text{O}_5 + 2\text{H}_2\text{O}$.
- Citric acid, $\text{C}_6\text{H}_8\text{O}_7 + 3\text{H}_2\text{O}$.
- Meconic acid, $\text{C}_6\text{H}_8\text{O}_7 + 3\text{H}_2\text{O}$.
- Saccharic acid, $\text{C}_6\text{H}_10\text{O}_7 + 3\text{H}_2\text{O}$.

In such acids there is always some hydrogen in the radical,
of which it is a constituent, and some combined with the
radical, which may be replaced by the metals. Amongst
the organic acids, there are some facts which seem to show
that this regularity is not always observed. Thus, meconic, meconic,
which is tribasic, forms like trisubphosphoric acid three
series of salts, in which one, two, or three equivalents of the
hydrogen are replaced by the metal. While but the meconic
acid, as well as the trisubphosphoric acid, readily forms
with the metals, meconic acid in the state in which it is
replaced by silver; it cannot form, or forms with difficulty, a
similar salt with potash, with which it forms very easily
salts with one and two equivalents of metal, and two or one equi-
valents of carbonate (Gregory). This fact is difficult to be
accounted for on the old theory, whilst it meets with an easy
solution on the new. The oxide of silver easily parts with its
oxygen, and there is no difficulty with it in substituting
three atoms of silver for three atoms of hydrogen, but the potash
does not unite with the oxygen easily, and we will not
form the compound with three equivalents of potassium.

Acroleine, $\text{C}_3\text{H}_4\text{O}_2$.
A substance obtained by Redten-
bach by the distillation of glycercine with phosphoric acid.
The operation must be carried on in vessels charged with
phosphoric acid, as acroleine is so rapidly oxidized in
atmospheric air, that it cannot be obtained where it is present.
It is a very pungent and suffocating substance, attacking
the eyes and nose of the operator if care is not taken. It is
composed of carbon, hydrogen, and oxygen, and may be
regarded as the hydrated oxide of a radical called acrylic.
This substance resembles acetylene, and represents in acro-
leine the position of acetylene in aldehydes. Thus, $\text{C}_3\text{H}_4\text{O}_2 + \text{H}_2\text{O}$
is the atomic constitution of acroleine. But this substance
becomes more easily oxidized when condensed between
into acryllic acid, ($\text{C}_3\text{H}_4^2 + \text{H}_2\text{O}$), a substance
perfectly analogous to acetic acid. Acroleine is often formed
as the result of the distillation of oils and fats. Thus, casteor

Oil yields acroleine, and some other peculiar products on
distillation. Glycerine may in fact be regarded as an hydrated
oxide of acryllic acid with three additional equivalents of water, as
follows:

- Glycerine, $\text{C}_3\text{H}_5\text{O}_3$.
- Hydrated oxide of acryllic, $\text{C}_3\text{H}_5\text{O}_6 + 4\text{H}_2\text{O}$.

Alumrine.
Acrylic acid.
Acrylic acid.

Alumrine, $\text{C}_3\text{O}_4\text{H}_4\text{O}_2$.
When oleic acid is acted on by nitrile, several new acids are formed, and amongst
them oleic acid.
It occurs in round radiant masses, fusible and volatile.

Alanine, $\text{C}_3\text{H}_5\text{O}_2$.
When aldehyde-ammonia [Chemistry—Aldehyd, $\text{C}_3\text{H}_5\text{O}_2$] is acted on by hydroxylamine, and
an excess of hydroxchloric acid, a crystalline body, soluble in cold
water, is formed. This body is known as alanime. It is homologous with
glycosecol and leucine, and isomeric with lactamide, urethane and sarcosine.
When acted on by hyp-
nitrous acid, it is converted into lactic acid, as follows:

$\text{C}_3\text{H}_5\text{O}_2 + \text{N}_2\text{O}_4 = \text{H}_2\text{O} + \text{N}_2 + \text{C}_3\text{H}_5\text{O}_4$.

Alanine.
Lactic acid.
Nitrogen is given off during the decomposition.

Aldehyd-ammonia. [Aldehyde, $\text{C}_3\text{H}_5\text{O}_2$].
Aldehyd.

Alumrine, $\text{C}_3\text{H}_5\text{O}_2$.
This acid was discovered by
Schlieper, and is formed by the action of hydrochloric
acid on alloxanone. It is soluble in 15 to 20 parts of hot
water, and on cooling it is deposited as a crystalline powder.
When the solution is evaporated it gives out:

Alloxanone, $\text{C}_3\text{H}_5\text{O}_2 + \text{H}_2\text{O}$.
This acid is un-
known in the hydrated or separate state. It forms crys-
talline salts with beryta, potash, and soda. It is pro-
cessed by the action of hydrochloric acid on alcohol. The
alcohol unites with the cyanic acid and forms the new
compound which unites with the oxygen of ethyl, and forms
an aliphosphate of the oxide of ethyl.

Thus, $\text{C}_3\text{H}_5\text{O}_2 + \text{H}_2\text{O} + \text{O}_2$.

Cyanic acid. Alcohol.

Cyanic acid. Alcohol.

Allyl, $\text{C}_3\text{H}_5\text{O}_2$.
A compound radical, regarded as the base
of oil of mustard. This oil is composed of carbon, hydrogen,
and sulphur, and sulphur, which may be arranged as follows:

- C$_3$H$_5$O + C$_3$N + O + H + O.
- Oxyd of ethylene. Aliphatic acid.

Aluminum, the metallic base of the earth Alumina, which
is composed of oxygen and the metal aluminium. Its equi-
valent or atomic weight is 13.7, and its specific gravity 2.6.
The metal is procured by decomposing the chloride of alu-
imium by means of alkali. The theory of the decompo-
sition is that the chloride unites with the potas-
sium or sodium, and leaves the aluminium free. The metal
is procured by washing away the chloride. Till very recently
aluminium, although well known, had been procured only in
very small quantities, and was regarded rather as a chemical
curiosity than a substance of any value. It differed however
from the other earthly and alkaline metals by its not being
readily acted on by the oxygen of the atmosphere or water.
Thus, $\text{Al}_2\text{O}_3 + 3\text{H}_2\text{O}$, however, it was announced that M. Stainville,
chemist to the Emperor of the French, had succeeded in
obtaining this metal in very considerable quantities, and so
readily as to lead to the supposition that it might be employed in
the arts. The method employed by M. Deville is precisely
the same as that which has been used for many years for
extracting iron, on account of its lightness, and not being acted on by
oxygen, would undoubtedly be valuable for a great variety
of purposes, provided it could be obtained at a low price. Its
cost however has been very considerable on account of the price of the metals by which it is obtained. Sodium is pre-
erred, and, in preference to potassium, but this metal has first to be obtained by costly processes. These
last have been greatly diminished, so that sodium has been recently sold for 10s. a pound. This still renders the price of aluminium a barrier to the general use of that metal. Nevertheless, it has been extensively manufactured in Paris into spoons, tea-pots, coffee-pots, and other articles of use.
In order to obtain aluminium, the chlorid is introduced into iron tubes and heated with the sodium.

The chlorid of aluminium, from which the metal is prepared, is not a natural compound, but has to be made from the earth alumina. It is prepared by mixing this earth, fresh precipitated with some form of carbon or carbonaceous substance, as charcoal, sugar, tar, &c., and the whole is made into a mass which is exposed to the action of an iron tube and heated with the sodium.

Ammonite, another name for Ammonite. Ammonite. Ammonium, C₇H₇N₄O, is one of the bases obtained from oil of turpentine, and is one of the bases procured by the long continued action of weak nitric acid on that substance. It is also formed in the preparation of isatin (Chemistry—Isatin, S. 1). It is identical with nitric acid, which is formed by the action of nitric acid on salicin. It is a solid, fusible, and amorphous substance, forming fine yellowish white prisms, which shrink in drying. It combines with bases forming anilates. The anilate of the oxide of methyl (or methyl-gallinum) is obtained by the action of nitric acid on the oil of gaultheria, which is a salicylate of the oxide of methyl.

Ammonolysis, a non-analysed vegetable substance found in Angelica root (Angelica Archangelica).

Ammoniac Acid is Indigotico Acid = Nitro-salicylic Acid, C₆H₅NO₂ + H₂O. This is one of the substances formed by the decomposition of indigo, and is procured by the process of distillation of animal matter or coal tar, is identical with aniline. The same distinguished chemist has added largely to our knowledge of this substance. He has shown that isatin, which is oxidised blue indigo when treated with potash, yields aniline, and that chlorarsonic and bromo-

Ammonolysis, a non-analysed vegetable substance found in Angelica root (Angelica Archangelica).

Ammonolysis, a non-analysed vegetable substance found in Angelica root (Angelica Archangelica).
aniline passes spontaneously into anisio-unas. For a full account of the chemistry of this highly important compound, the reader is referred to the paper of Dr. Hofmann.

Anilotic Acid, C₆ N O₂ C₆ H₄ O₂, is a compound of aniline and cyanic acid.

Anilomelleone, C₆ H₅ N₃ O, a compound of aniline and maleic anhydride, is obtained by the heating of maleamide.

Anisidine, a substance obtained by acting on the oil of anise by strong acids, or the chlorides of tin or antimony. It is analogous to benzene.

Anisole, C₆ H₅ N O, is a compound of anisic acid and alcohol. It is obtained by heating anisic acid, which is itself obtained by oxidising the steapentone of oil of anise with nitric acid. Anisole is the radical of anisic acid when it is decomposed, C₆ H₅ O."
obtained in any quantity by fermenting sugar with cheese and adding chalk. Carbinic acid and hydrogen gases are set free.

**Cynane of Propyle, C₆H₇N.** It is a question whether this compound is a true cyanide, or a nitrite. It is formed among the products of the oxidation of albinous compounds.

**Butyramide, C₅H₇O₂N H₂.** This substance is produced by the distillation of the butyrate of the oxide of ethylene with ammonium in closed tubes.

**Butyron, C₃H₇O.** This substance is homologous with acetone and propione. It is less volatile than propione. It is prepared by heating the butyrate of baryta.

**Butyrobarbiturate of Ethylene, C₃H₇O₂N H₂.** This is a very fragrant and delicious ether, and is the principal element of the flavour found in the pine-apple, the melon, and some other fruits. It is this substance which is developed during the fermentation of the sugar from which rum is procured, and which appears to have got for this form of ardent spirits the name of pine-apple rum. This ether dissolved in alcohol, is sold in the shops under the name of essence of pine-apple, and is used for flavouring confectionery, &c. It is developed in rum more fully after long keeping. It is also found in some wines, and with acetic ether is one of the principal sources of their flavour.

**Camphor, C₁₀H₁₆.** This substance is obtained when common camphor (C₁₀H₁₆O) is distilled with dry phosphoric acid. It is found also in the oil of cumin. It forms with sulphuric acid a compound, called sulphophenylcyclohexanecarboxylic acid, C₆H₄SO₃C₂H₅ H₂O⁺ H₂O. **Camphoracid, C₁₀H₁₆O⁺ H₂O.** This acid is formed by the action of nitric acid on camphor. It occurs in the form of crystalline scales, which fuse at a temperature of 186°C, with the loss of carbonic acid, but sparingly soluble in cold water. When distilled, these scales are resolved into anhydrous camphoric acid and water. This acid combines with the oxide of ethylene, and forms two compounds:

1. **Camphoric ether,** an oily liquid, with a bitter taste and a nauseous smell.
2. **Camphorinic acid,** which has the power of forming soluble salts.

**Anhydrocamphoric acid, C₁₀H₁₇O⁺ H₂O.** forms a different substance from those constituted by the hydrated acid. It is a solid crystalline and volatile body, and yields an acid amide called camphoramic acid.

**Sulphocamphoric acid** is formed by the action of sulphuric acid on anhydrous camphoric acid with the disengagement of carbonic oxide. **Camphorinic Acid.** [Camphoric Acid.]

**Camphorn, C₁₀H₁₇O.** This substance is formed when camphor is passed over red-hot lime.

**Camphorose, C₁₀H₁₈O.** When camphorose (Indian rubber) is exposed to the action of heat, it first melts and then distils, and yields several oils which, like camphorose itself, are compounds of carbon and hydrogen. One of these is camphorose, which combines with chlorin, forming an oil C₁₀H₁₈Cl.

**Capral (Caproic Acid), Capramide, is produced by the action of ammonia on the caprate of the oxide of ethylene.** It occurs in the form of shining scales, which are fusible below 218°C. It is soluble in alcohol, and insoluble in water.

**Capral, C₆H₅O⁺ H₂O.** This acid is formed with many others from butter and goat's fat. It is also produced by the oxidation of the oil of rue. It has also been found in the oil of grain. It is a solid, fatty body, melting at a temperature of 40°C. It is sparingly soluble in hot water, and crystallises in the form of a white silky powder. When heated with caustic potash it yields a black acid called Japonic acid. Carbonate of potash produces in it a red crystalline compound, which is a red colour.

**Cathantine, the active principle of the various Cacti, which are used under the name of Sonna.**

**Cedrer, one of the products of the distillation of coal tar discovered by Reichenbach.** It is a volatile solid, and is obtained from coal tar. It is produced by boiling it with an alcoholic solution of potash. It crystallises in a solution of sulphate of iron, forming orange-red crystals, which dissolve with a blue colour in sulphuric acid. The colour of oil of tar seems to be owing to this substance.
Chenopod, the compound $\text{C}_6\text{H}_7\text{Cl}_2$ is Chinopolanin.

The same plan is pursued with bromine. But in all these cases the hydrogen may be replaced by atoms of both chlorine and bromine. In the same way the vowels are made to do duty for these compounds, as follows: chlorophosphate, $\text{C}_6\text{H}_7\text{Cl}_2\text{Br}_2$; chlorobromophosphate, $\text{C}_6\text{H}_7\text{Cl}_2\text{Br}_2$; chlorobromophosphate, $\text{C}_6\text{H}_7\text{Cl}_2\text{Br}_2$; chlorobromophosphate, $\text{C}_6\text{H}_7\text{Cl}_2\text{Br}_2$; chlorobromophosphate, $\text{C}_6\text{H}_7\text{Cl}_2\text{Br}_2$. All these compounds are capable of acting as bases and combining with elements. Thus we have chloride of phosphorus, $\text{C}_6\text{H}_7\text{Cl}_2\text{P}$, and oxides of chlorophosphates, &c., bromide of chlorobromophosphates, &c.

Chlorosol [Chlorosol.] -- Chlorosol, $\text{C}_6\text{H}_7\text{Cl}_2\text{H}_O$, is one of the products of the action of nitric acid on chlorosol. It is a yellow solid, $\text{C}_6\text{H}_7\text{Cl}_2\text{H}_O$, in which it will be seen are contained all the important elements of the acid.

Chlorosol, $\text{C}_6\text{H}_7\text{Cl}_2\text{O}_3$, was first discovered in the bile by Gmelin. It is prepared by allowing a solution of dry bile in alcohol to be mixed with ether, when it deposits a crystalline solid. This is decomposed by sulfurous acid, and groups of radiated crystals are deposited, which are cholic acid. It is decomposed when heated with mineral acids and potash.

Cholestane, $\text{C}_6\text{H}_7\text{O}_3$, is produced from the decomposition of clavicular acid when boiled with acids. It is cholic acid with one equivalent less water. Cholic acid is uncrystallizable, and its salts are amorphous. This substance was formerly called resin of bile. When cholic acid is treated with hydrochloric acid, it is converted into a neutral substance, $\text{C}_6\text{H}_7\text{O}_3\text{N}_2$, by the loss of three equivalents of water.

Chromatophores, $\text{C}_6\text{H}_7\text{O}_3\text{N}_2$, is a compound of chromium and cyanogen. It combines with potassium, forming a yellow crystalline salt.

Chtistex, $\text{C}_6\text{H}_7\text{N}$, is one of the numerous compounds formed in coal tar. It is a yellow crystalline solid, melting at a temperature of 45°.

Chromophoic Acid, $\text{C}_6\text{H}_7\text{O}_3$, is found in the Permainia varista. It occurs in the form of golden yellow crystals, and with solutions of potash and ammonia, in alcohol, yields a beautiful red colour.

Cinnamaldehyde, $\text{C}_6\text{H}_7\text{O}_3$, the hypothetical radical of essence of cinnamomum.

Hydrate of Cinnamyl, $\text{C}_6\text{H}_7\text{O}_3\text{H}_2$, is the purified essence or oil of cinnamon. It is a fragrant oil, and forms with nitric acid a crystalline compound, $\text{C}_6\text{H}_7\text{O}_3\text{H}_2\text{N}_2$, which, when mixed with water, is resolved into its original elements, $\text{C}_6\text{H}_7\text{O}_3\text{N}_2$. When this oil is exposed to the air it absorbs oxygen, and becomes converted into cinnamic acid, $\text{C}_6\text{H}_7\text{O}_3\text{H}_2$. This acid is also easily obtained by dissolving oil of Balsam of Peru in a solution of potash in alcohol, evaporating to dryness, dissolving in hot water, and adding to the cinnaeate of potash the former, hydrochloric acid. Nitric acid converts it into the hydriat of benzoyl. When added to cold nitric acid it is converted into nitro-cinnamic acid. The salts of this acid are volatile.

When chlorine is applied upon fusing sulfurous acid, sulfo-cinnamic acid is formed.

Cinnamaldehyde, $\text{C}_6\text{H}_7\text{O}_3$, is found in Balsam of Peru. It contains cinnamic acid united to an ether.

Cinnamyl, $\text{C}_6\text{H}_7\text{O}_3$, is formed when cinnamic acid is distilled with baryta.

Citroconic Acid, $\text{C}_6\text{H}_7\text{O}_3\text{H}_2$, is formed from Iaconic acid, $\text{C}_6\text{H}_7\text{O}_3\text{H}_2$, which is again formed from Acetic acid, $\text{C}_6\text{H}_7\text{O}_3$. The last acid is found in the Aconitum Narpeatus, and in the Cinnamaldehyde.

Cinchine, $\text{C}_6\text{H}_7\text{O}_3\text{N}_2$, an active principle found in the group Cynaraeehele of the compositional order of plants. It is neutral and bitter.

Chelerythrine, the active principle of the meadow saffron (Chelerythrine), $\text{C}_6\text{H}_7\text{O}_3\text{H}_2$, has a taste at one time regarded identical with veratrine. It is soluble in water, alcohol, and ether. It forms salts with the acids, which are bitter, acrid, and poisonous. In small doses it causes purging.

Chelidonic acid is formed in the cercidacee of the plant Chenopodium.
Compound Radical. A term applied to those combinations of the elements which act towards oxygen, hydrogen, and acids, as simple elements. Examples of such compound bodies will be found under the heads, amyl, butyl, cetyle, and camphenyl, &c.

Collodion. [Gun Cotton.]

Creatine, C6H5N2O2. This body, originally discovered by Chevreul, occurs in transparent very brilliant crystals. It is also found in the urine of persons suffering from a state of phthisis. It dissolves in 74 parts of cold water, and in boiling water in such quantity that on cooling the solution becomes consolidated into a mass of glistening needles. It dissolves in alcohol, but not in ether. It forms no definite salts with acids. According to Liebig it is best obtained from finely chopped flesh that has been well kneaded with water, and the fluid removed by pressure. The exudable matters are then removed by boiling, and the phosphates by a solution of baryta. The fluid left is then evaporated till the creatine is deposited in the form of needles. Creatine can also be obtained from the urine. It appears to be produced in the flesh of animals as the result of a process of retrogressive change in the elements of the tissues in which it is found. It is in fact a product of excretion.

Creatinina, C6H4N2O3, was discovered by Liebig. It is obtained from creatine by the action of hydrochloric acid. It is found also in the muscles and the urine, with creatine, which is an essential constituent of their normal condition. But in petrified flesh and urine no creatine is found. Hence creatinina may be regarded as the result of the decomposition of creatine.

Cumidine, C7H8N2, is obtained from the oil of cumin. It is the crystalline base, resembling anistane; and like that base it combines with chlorine, bromine, &c. Cumidine, C7H8N2, is found in the oil of cumin and in the oil of coriander. Cymidine, C7H8N2, and cymol, C6H10O, are found in companies with the above compounds in the same oil.

Cyamylene, C6H6O2, is the essence of the latter. This substance is formed by the decomposition of cyanic acid when left to itself. It is an opaque white solid body, which has no acid properties. It dissolves in a liquid potassa with disengagement of ammonia, and a little water is used for its solution.

Diphtyle, C10H14O, is obtained by heating oil of turpentine with lime. It is a pure oil.

Diamylamine. [Amyl.]

Dihydroaminline. [Amyl.]

Dichloraminline. [Amyl.]

Diethylamine. [Amyl.]

Dietylamine. [Chloric acid.]

Elaidic acid, a fatty acid, obtained by the action of nitric acid on oleic acid.

Ethylene. When aldehydes have been kept for some time in sealed tubes, it has been found to be converted into two polymeric bodies, metaldehyde, a hard crystalline inodorous solid, and elaldehyde, which is a liquid.

Ethylcarboxylic acid, ethylcarboxylic acid, C6H4O2. One of the acids found in the Perentia roccella and Ruccella tineoria, lichens which yield the commercial substance arachis. This acid is the most important of all the principles found in lichens. It yields ether when boiled with alcohol. Besides its eutropic, eutonic, alpha acetole, beta acetole, and rassidic acids have been found in lichens. They yield red dyes with ammonia, and are employed extensively in the dying of cotton and woollen cloth. These acids have been investigated by Schunck and Stenzhoven, and the latter recommends that the latter in three parts of water, and which are not possessed by lichens in larger quantities than 2 to 12 per cent., should be separated on the spot where they grow, and thus spare the expense of the carriage of the useless parts. These acids are extracted by the following process:

The lichens cut in small pieces are moistened with water, and after standing half an hour slaked lime is added, and the mixture allowed to stand for a time. It is then placed in a vessel with a double bottom, the upper being perforated and the lower filled with water. As the water is evaporated, so as to drop which gives a deep purple red colour with bleeding liquor, a character belonging to all the acids which yield arachis. The solution is then saturated with hydrochloric acid, and a gelatinous precipitate falls, which is then separated; then the acids are extracted by means of water, which are then separated. Thus the acids are extracted from the 'oak acid' without boiling, which will form ether compounds.' (Gregory.) Besides the acids there are three other compounds found in the lichens used for dying—Orincine, Picoeroinhyine, and Brythromannite.

Orincine, C6H4N2O2, occurs in the form of large transparent crystals. It has a sweetish taste, and is very soluble in water. When mixed with ammonia and exposed to the air, it assumes gradually a deep red colour, and when mixed with the fixed alkalis it has a rich violet colour.

Picoeroinhyine = Erthyrin—bitter = Amarynth, C6H6NO3, is formed when ethyric acid, or the lichens containing it, are burnt. Erthyrin, C6H4O3, is formed when picoeroinhyine is boiled with baryta. It is dissolved by water and alcohol. It forms large colourless crystals, which have a sweet taste.

Ethyal [Cetyle.]

Ethylal [Cetyle.]

Ether, Butylage [Butyle.]

Ether, Camphorose. [Camphoric Acid.]

Ether, Amylic. [Amyl.]

Ethylamine. [Ethyle.]

Ethyle, C6H12. One of the earliest known of the compound radicals, and the base of the well-known substances ether and alcohol. It was for a long time unknown except in combination. Frankland, however, at last succeeded in separating it by the action of zinc in closed tubes upon the iodides of ethyle. The following equation expresses this result:

C6H5 + I + Zn = ZnI + C6H5. Part of the ethyle, however, is converted into zineethyle, C6H5 + Zn, and another part into methyl and ethyle. In the latter case of the decomposition of the ethyle, the carbon becomes a colourless gas, having a faint smell like ether, and burning with a bright flame. It has a specific gravity of 2.00394, and is condensed into a liquid with a faint smell.

Oxide of Ethyle = Ether = Sulphuric Ether, C6H5O. This ether is occasionally found in nature combined with acetic, butyric, and other ethers, which are found giving beautiful samples of its aromatic and ethereal qualities. This compound is obtained from alcohol by acting on it with sulphuric acid. [Ether.] Ether is now known to be perfectly analogous to the metallic oxides, its compound base ethyle taking the part of the metal. Thus, as K.O represents acetic of potash, and KO represents benzoate of potash, so C6H5O represents acetic of alcohol, and C6H5O represents benzoate of ethyle. [Ether.]

Hydrated Oxide of Ethyle = Alcohol, C6H5O + H2O = C6H5O2. This substance is formed when ether and water meet in their nascent state, as when some of the acid salts of ethyle are decomposed by heat. It is however produced during the distillation of ethyle or alcohol, which is composed of C6H5O2. During fermentation this compound loses 4 atoms of carbonic acid and leaves behind 2 atoms of the hydrated oxide of alcohol. Thus

Glucose

2 atoms of alcohol

2 atoms of alcohol

4 atoms of carbonic acid .

Azemoloc, P.C.

Chloride of Ethyle, C6H5Cl, is formed by saturating alcohol with hydrochloric acid, and distilling the mixture in a vapour-bath, when the chloride of ethyle passes over.

Bromide, Iodide, and Sulphide of Ethyle, are analogous compounds, consisting of one atom of ethyle and one of the other element.

Hydrosulphuret of Sulphuret of Ethyle = Mercaptan, C6H5S, or C6H5H+S, is formed when the double sulphate of lime and oxide of ethyle is distilled with its own alkali of a sulphuret of potassium, with saturated with sulphuret of hydrogen, and converted into K + S + H.S. It has a powerful and penetrating odour, smelling like the essence of onions concentrated. It adheres to the hands and clothes most perniciously, and is a most offensive subject to operate upon. Zeus has the odour of hydrosulphuret of ethyle and sulphuret of potassium. It is a volatile liquid, having an offensive allisious odour.

Cyantide of Ethyle, C6H5-Cy = C6H5N2 is procured by heating cyanide or ferrocyanide of potassium with the double sulphate of potash and ethyle. It is a very offensive compound, smelling like putrid fish. It produces stufication when inhaled.

Oxide of Ethyle unites with sulphuric and phosphoric acid.
acids, forming sulphates and phosphates. Nitrates of the oxides of Ethyl, $C_2\text{H}_4\text{O} + N\text{O}_3$, is the Nitre Ether of Nitrous Oxide, but the least least of the various theonic agents which have been recently employed in medicine. It is a liquid, having a specific gravity of 1.50, and is transparent, colourless, and volatile. It is best obtained by distillation with alcohol and with water to the boiling point (chlorinated lime). It is then well washed with water and redistilled, and washed with sulphuric acid to remove the water and other adulterations. [ANESTHETICS—MATERIA MEDICA, S. 2.]

When the fumurate of oxide of ethyl, which is a heavy oily liquid, is acted on by aqua ammoniac, it forms a white insoluble powder, which is fumarae, and possesses all the characters of a compound amide. The oils which contaminate potato and grain spirit are called by the Germans under the common name fueseld, and the same term translated is applied by English chemists to these oils. Potato spirit is accomplished by the hydrated oxide of amyle, or oil of potato spirit [ANHYDROUS], whilst grain spirit is accomplished by an oily matter consisting of margaric, capric, and cynamic acids, which probably, with the spirit form their corresponding ethers. Dr. Gregory suggests that this is probably the composition of the Glyceryl, $C_3\text{H}_6\text{O}_2$, of the Oleum Murd. [ACROLEIN, N. 1.]

Oxins, a name given to humus in common with ulicina, humic acid, ulmic acid, humine and geic acid. This substance is obtained from common mould, which when boiled with alkalis, and the solution filtered and treated with acids, yields a substance, which has the name of Oxin. [ACROLEIN, N. 1.]

Omea*, a non-aërial vegetable compound, obtained in the form of yellow needles from the Gentiama latua. Glaucesin, an alkaloid found in the leaves and stem of Glaucium tinatum. It forms salts with the acids, and has a little bitter taste. It is a volatile volatile, which occurs in the plant, differs from the above compound. The composition of both is doubtful.

Glyceryl, $C_3\text{H}_6\text{O}_2$, is the hypothetical radical of the substance called Glycerine, which is the hydrated oxide of Glycine, $C_3\text{H}_6\text{O}_2 + H_2O$. [ACROLEIN, N. 1.]

By the action of heat Glycerine is decomposed, and a volatile principle is produced, which is called Acrolein. [ACROLEIN, N. 1.]

Glycerine is the substance that combines with the fatty matter, fats, and oils. Berzelius, however, has suggested that this compound is not present in some fats, but that a body having the composition $C_3\text{H}_6\text{O}_2$ occurs, and which has oxide of lipide. Two atoms of this substance with three of water will form the hydrate of the oxide of glycerol; thus, $C_3\text{H}_6\text{O}_2 \cdot 3 (C_3\text{H}_6\text{O}_2) + 3 H_2O$.

Glycocin = Glycosol = Sugar of Gelatine, $C_3\text{H}_6\text{N}_3O_8$ is a compound found amongst the products of boiling gelatine with potash or acids. It may also be prepared by heating hippuric acid with hydrochloric acid, when benzoic acid, water, and glyccolin are produced. It forms transparent crystals, which are soluble in water and sweet to the taste. It combines with acids and bases. Its easy formation from the animal compound gelatine, has led to the supposition that it may play an important part in the animal body.

Guaiacyle, $C_3\text{H}_4O$, the theoretical base of the resin called guaiacum. If this resin is distilled, an oily liquid is obtained, which is regarded as a hyduret of guaiacyle, $C_3\text{H}_6O + H_2O$.

Guadin, $C_3\text{O}_2N_2O_4$, a compound discovered by Unger in guano. It resembles urea in its properties, forming crystalline, tasteless salts with hydrochloric, sulphuric, and nitric acids. It is a white powder, and soluble in water. Its salts are all neutral or acid, none basic.

Guadin, $C_3\text{H}_6O_4N_2$, a substance identical with thine and caffeine, and found in the Guarania officinalis.

Gum-Corrus, a substance discovered by Professor Schieb, being a gum obtained by simmering down ten parts of an acid composed of equal parts of sulphuric and nitric acids. After immersion for about two minutes, the wool is withdrawn and the liquid is pressed out, and it is rapidly washed with water till all remains of the crude zone. One hundred parts of cotton thus treated yield one hundred and sixty-nine parts, of which one hundred and two
are nitric acid, water has disappeared, and the rest is cellulose.

It is often sold to carpet and feschemacher, gun-cotton consists of C\textsubscript{10}H\textsubscript{8}O\textsubscript{2}, 4\textsubscript{10}O. If it is not dried it is superseded by gunpowder, as in fire-arms its explosive force is inferior, but in the blasting of rocks it possesses some advantages over gunpowder. Gun-cotton is soluble in ether, and a compound is formed in delicate bags into which hydrogen may be introduced for balloons. In photography the colloid is mixed with the iodides to be acted on by light, and, being spread on glass, pictures from which any number of impressions may be taken, are produced. Hall, C\textsubscript{10}H\textsubscript{8}N\textsubscript{4}O\textsubscript{2}, is alkaloid occurring in the seeds of Peganum Harmala.

They are united with phosphoric acid. Harmaline forms yellow salts with the acids, and is transformed into a red salt by oxidising agents. The harmal red of commerce is the powder of the seeds. It is used in dyeing red, rose-colour, and pink. It is used in large quantities in Russia. Harmeline yields a number of substitution products, such as nitratin, aluminoharmaline, &c.

Harmine, C\textsubscript{10}H\textsubscript{8}N\textsubscript{4}O\textsubscript{4}, a compound formed when salyacine is acted on by diluted nitric acid. It contains the elements of sugar and hydrost of hydrogen. It crystallizes in the form of minute, transparent prisms. When heated in 300\textdegree C it forms a resinous insoluble substance.

Harmeline, C\textsubscript{10}H\textsubscript{8}N\textsubscript{4}O\textsubscript{4}, is a concrete volatile principle allied to the essential oils. It is a solid crystalline body, and is derived from the Jauda Helminthum. With nitric acid it yields nitro-harmeline, &c.

Harmic Acid, C\textsubscript{10}N\textsubscript{4}H\textsubscript{4}O, is found in large quantities in the urine of the cow and horse, and other herbivorous animals. It has also been detected in human urine. It is prepared by boiling the urine of the horse or cow with a small bulk, and decalcifying with hydrochloric acid. The mixture deposits brown crystals of hippuric acid, which may be made white by boiling with lime, and dissolving the hosphate of lime, and again adding hydrochloric acid, when the pure hippuric acid is thrown down. It forms large semi-transparent four-sided prisms, which are sparingly soluble in cold water, and very soluble in hot water and in alcohol. Under heat it melts and gives off benzoic acid, benzate of ammonia, and a fragrant oil. It forms salts which are soluble and crystallizable.

Harmic Acid. [G. Hmin.

Harmine. [G. Hmin.

Harmine Acid, C\textsubscript{10}N\textsubscript{4}H\textsubscript{4}O, discovered by Unger, and formed by boiling cane sugar with hydrochloric acid and chloride of potash. It differs in composition from uric acid by 1 equivalent of water and 2 of oxygen, hence its name. It is colourless, and crystallizes in short rhombic prisms, and when heated, is resolved into hydrated cyanic acid, water, and carbon.

Harmine Acid, C\textsubscript{10}H\textsubscript{8}, a hydrocarbon found in the mines of Idria. It colours sulpheric acid intensely blue. It is probably identical with succiniterene, a substance obtained from amber, and which has the same property of colouring oil of vitriol intensely blue.

Harmine Acid, C\textsubscript{10}H\textsubscript{8}O\textsubscript{2} + 4H \textsubscript{2}O, is a peculiar species of sugar, discovered by Scherer in the juices obtained from the flesh of animals. It crystallizes in large crystals, which have a sweet taste, but which do not enter into a state of fermentation. It yields, however, both lactic and butyric acids when exposed to the action of caseine. It differs from glucose in not giving the usual reaction with the salts of copper and potash, and in possessing two atoms more water in its composition. It has not yet been found ready formed in the animal system.

Harmine Acyrogen, C\textsubscript{10}N + Ir, is a hypothetical compound radical. It forms with hydrogen triiodic acid, and with potassium, a compound of potassium, of a form of colourless crystals, and gives a deep indigo blue with the salts of peroxide of iron. This is one of the many compounds of a metal with cyanogen, like ferrocyanogen, and which have all the power of combining with other metals possessed by that body. Thus there are cobaltocyanogen, chromocyanogen, platinocyanogen, &c.

Isatinic Acid, C\textsubscript{10}H\textsubscript{8}N\textsubscript{4}O\textsubscript{2} + H\textsubscript{2}O, is formed by the action of a strong solution of potash on isatin, C\textsubscript{10}H\textsubscript{8}N\textsubscript{4}O. The compound forms a pale solution of starch, from which the isatinic acid may be separated. It is, however, at once resolved into isatin and water, but if isatinic acid is treated with sulphurised hydrogen in vacuo, a white flocculent powder is obtained, which becomes red on being dissolved by boiling water, and the solution on cooling deposits isatin.

Isatinic acid unites with the metals, the latter representing in the various compounds the hydrogen of the water.

Isatide, C\textsubscript{10}H\textsubscript{8}N\textsubscript{4}O, is a product of isatin, when this substance is heated with baryta, ammonium, arsenic, and a grey crystalline powder, and represents isatin with one equivalent of hydrogen. This equivalent of hydrogen may be supplied by chlorine and sulphur, and thus chlorisatin and sulphisatin are produced. Isatinic acid forms with Suraminine in the Geofroia phymatina and G. Suraminens. They are crystallizable alkaloids, capable of forming with the acids salts, which are precipitated with tartrine and corrosive sublimate.

Kakodine. [Kakodyl—CHEMISTRY, S. 1.]

Kino or Quinic Acid, C\textsubscript{10}H\textsubscript{8}O\textsubscript{4} + 2 H\textsubscript{2}O, is obtained from cinchona bark, in the manufacture of sulphate of quinine. It occurs in the bark united with the quinine, and when lime is added to a solution of bark, a kinate of lime is formed. The kinate of lime is used as a substitute for the kinate of lime, and for the mineral water contents of mineral water, which is so soluble in water, having a pungent smell when the state of the vapour. When kine is acted on by reducing agents, it takes up 2 and 4 equivalents of hydrogen, forming green and white hydrogen kinate. The first forms a crystal of crusts of exceeding beauty, the latter are white. Woehler has obtained several compounds of kine, of which the following tabular statement gives the names as far as they are yet known:

Kino... C\textsubscript{10}H\textsubscript{8}O\textsubscript{4}

Green hydrokinate... C\textsubscript{10}H\textsubscript{8}O\textsubscript{4}

White hydrokinate... C\textsubscript{10}H\textsubscript{8}O\textsubscript{4}

Chlorhydrine... C\textsubscript{10}H\textsubscript{8}ClO\textsubscript{4}

Chlorokinate... C\textsubscript{10}H\textsubscript{8}ClO\textsubscript{4}

Brown sulphhydrine... C\textsubscript{10}H\textsubscript{8}S\textsubscript{4}O\textsubscript{4}

Yellow sulphhydrine... C\textsubscript{10}H\textsubscript{8}S\textsubscript{4}O\textsubscript{4}

Brown Chlorosulphokinate... C\textsubscript{10}H\textsubscript{8}ClO\textsubscript{4}

Orange... C\textsubscript{10}H\textsubscript{8}ClO\textsubscript{4}

Kreatine. [Kreatine.

Kreatinine. [Kreatine.

Kynole. [Aniline.

Lactamide, C\textsubscript{10}H\textsubscript{8}N\textsubscript{4}O, is obtained by the action of lactic acid on ammonia. It is interesting as being identical in composition with the body, isolated from the leishman which are urethane (carbamate of the oxide of ethylene). They have all of them, however, very distinct properties. This substance differs from the others in yielding lactic acid and ammonia when acted on by acids, hence its name.

Lactargine is the active principle of the Lactaæa vivipara, or wild letuce. It is obtained from the juice of this plant, which is called Lactascarium. It is a bitter, crystalline, resinoid substance, possessing anodyne properties.

Lamic Acid. Another name for Aldehydic acid. [ALKYDIOIC ACID—CHEMISTRY, S. 1.]

Lactic Acid, C\textsubscript{10}H\textsubscript{8}O\textsubscript{4}H, a crystalline fatty acid, obtained from the fat of the berries of Laurus nobilis. It forms a salt with the alkalies. Lecanora, C\textsubscript{10}H\textsubscript{8}O\textsubscript{4}H, is found in several lichens, especially Lecanora tartarea, and Gyrophora purpulata. It occurs in the form of minute white crystals, which are insoluble in water, but soluble in ether and alcohol. When heated with alkalis, it yields a carbonate of the alkali, and a sweet substance called oxine. Thus:

C\textsubscript{10}H\textsubscript{8}O\textsubscript{4} + 2 CO\textsubscript{2} + C\textsubscript{10}H\textsubscript{8}O\textsubscript{4}

lecanoric acid.

lecanoric acid.

The same change takes place when lactic acid is boiled in water. By the action of air and ammonia, this acid is gradually converted into a deep blue or purple colour (Estyrich Acid). This acid combines with bases, and with bases, and bases.

Lecanoramic Acid, C\textsubscript{10}H\textsubscript{8}O\textsubscript{4}H, is the yellow dyes of the Pseudorubrina of Heeren, and the Estyrich of Rassum. It is produced by boiling the lichens with alcohol. It was dis-
covered by Schunck, to whom chemistry is greatly in debt, for a knowledge of the compounds contained in the lichens.

Leucoroea is the name given to a substance possessing the properties of gum, and which is produced by simply exposing starch to a temperature of 300°. It has a brownish yellow colour, and acts in the same manner as gum, and is externally used instead of this substance in calico printing.

Lucic Acid, C₂₀H₁₇O₄, an organic acid belonging to the leucine series. Leucic Acid C₂₀H₁₇O₄ is a substance identical in composition with glycocine and alamine. It has the same relation to valeric acid that they have to formic and acetic acids. It forms crystalline scales, which are volatile, and when heated with peroxide of hydrogen, acetic acid, sulfuric acid, and hydrochloric acid. This substance has been detected in the liver of the calf as a natural product. It is also found among the products of the putrefaction of fibrous and albumen.

Lucoline = Quinoline, C₇H₈, is one of the compounds found in the least volatile portions of the basic oil of coal-tar. It is also formed when quinine, cinchonine, strychnine, or thiaidine are heated in contact with potash. It is a liquid with a disagreeable smell, and boils at the temperature of 460°. It neutralises acids, and forms with the salts.

Lucorohamine. [Halihaline.]

Licinine, C₂₀O₁₈H₂₀, is a variety of starch found in the Lichin islandicus, or Iceland moss. It is colourless and tasteless, and forms a jelly-like mass in cold water and dissolves in hot. Its solution is not coloured blue by iodine, but the jelly is. It is converted into sugar by dilution and boiling sulphuric acid.

Limonine, C₁₅H₂₀O, is a bitter crystalline substance found in the seeds of lemons and oranges. It closely resembles Cinine, the bitter principle of the Cinnarespinha. It contains 2 atoms less water.

Lipide. [Glycine.]

Liphine, C₆H₈N₂, is one of the bases derived from the oil of the common lichens. It is formed when hydrobenzoide (C₆H₈N₂) is distilled. Ammonia is given off, and liphine left undissolved. It is soluble in alcohol with acids, and precipitated again by ammonia. It occurs in the form of fine silky crystals, and acts towards acids in the manner of a base. By the action of nitric acid it yields a yellow crystalline compound called trihydroxyphyline.

Luteolin is a non-organic colouring principle found in the word (Istes tinctoria). It is volatile and crystallisable.

Luteolin and Malamine Acids, are synonyms of Asparagine and Aspatic acid. [Asparagine - Chemistry, S. 1.]

Melampaprine is a crystalline non-oxidised substance obtained from the cow-wheat, Melampyrum nummularium. It is an organic compound hitherto unknown.

Melanic Acid, C₂₀H₁₇O₄, is formed from cane sugar by the action of heat and alkalies. It has a very dark colour, and when thrown down by hydrochloric acid appears as a black flocculent deposit.

Melasin Acid, C₂₀H₁₇O₄, is one of the substances yielded by wax. According to Brodie, when the hydrated oxide of melasine or melasine is heated with lime and potash, it yields hydrogen gas and melasinate of the base. When the acid is separated, it presents itself as a crystalline wax substance, melting at 192°.

Melline. [Melline - Chemistry, S. 1.]

Mellin, C₂₀H₁₇O₄, a negative radical found in myricine, a substance which forms about four-fifths of bees’ wax. It consists of the hydrated oxide of melasine combined with palmic acid. The palmic acid is easily separated from the hydrated oxide of melasine by saponification. The latter is a true alcohol, and, like common alcohol, yields a carbohydrate resembling ethanal gas. Its composition is C₂₀H₁₇O₄. It is identical with melasine or melasnic alcohol. This compound is very interesting, as it has been shown by Brodie to possess the same relations, and to form a series of compounds homologous with those of ethylene and methylene, the latter two of which are known.

Menbrerine, C₂₀H₁₇NO₄, is a white fusible crystallisable alkaloid, forming salts with the acids found in the seeds of the Menispermum Cocculus, known as Cocculus Indicus.

Menbracine is a non-oxidised uncrystallisable neutral principle found in the common buck bean, Menyanthes trifoliata.

Methicole, C₂₀H₁₇O₄, is obtained from the distillation of acetone with fuming sulphuric acid. Thus, 3 equivalents of acetone = 3(C₆H₄O₄), yield 6H₂O and mesitylole. The atoms of hydrogen may be substituted by chlorine, bromine, and nitrous acid.

Metascopic Acid, C₂₀H₁₇O₄+H₂O, is an acid described by Gottlieb and obtained from the action of nitric acid on citraconic acid. It forms minute crystals, sparingly soluble in water.

Methionone Acid, S₈O₄C₂H₂O₄, this acid with Ethionic, Iethionic, and alicionic acid is formed by the action of sulphuric acid on ether and alcohol.

Methyl alcohol. [Aline.]

Methylidithyramyllium. [Aline.]

Methylidithyramyllamine. [Aline.]

Myosilibrium. Balsam of Peru, according to Richter, contains two oils, myroxylne, which is insoluble in alcohol and myrospermine, which is soluble in that liquid. The latter substance when treated with an alcoholic solution of potash yields a yellow resembling cinnamic acid, which is called myrospermic acid.

Myristic Acid, C₆H₄O₄+H₂O, is a crystalline fatty acid found in the seeds of Myristica noothaca, the common nutmeg. When united with the oxide of lime, it forms the fat of the nature with the oxide of ethylene a myristate which is an oily liquid.

Naphtharline, C₆H₄O₄, or C₆H₄O₄, is found in all kinds of tar, but especially in coal tar. It is easily obtained by redistilling this last product when it occurs in a semi-solid state. It may be then purified by sublimation and crystallised from hot alcohol. It is colourless and volatile, forming large tabular transparent crystals, with a peculiar smell and an acrid taste. It is volatilised like camphor by exposure to the air, and boils at a temperature of 414°. It forms with bromine and chlorine a large number of compounds by substitution, and is acted on in the same way by sulphuric and nitric acids. These compounds have been studied with great diligence and singular accuracy by Laurent, who has found on them great force of substitutions, which has been one of the most remarkable aids to the development of modern organic chemistry. [Chlorophenolase.]

The compounds of chlorine and bromine with naphthalene are of very great importance, have been carefully described by Laurent. The whole of the possible compounds of these two elements with naphthalene amounts to the large number of 1040. In the same manner sulphuric and nitric acids are found to act on naphthalene, and to give a large number of compounds highly interesting to the chemist, but which have not yet been fully studied. The following are a few examples of these compounds:

Hyposulphonaphthalic acid. C₆H₄O₄S⁺H₂O.

Hyposulphonaphthalic acid. C₆H₄O₄S⁺H₂O.

Sulphonaphthalic acid. C₆H₄O₄S⁺H₂O.

Sulphonaphthalic acid. C₆H₄O₄S⁺H₂O.

Nitronaphthalin Acid. C₆H₄N+O₄.

Thionaphthalic Acid. C₆H₄N+O₄.

Nitronaphthaline Acid. C₆H₄N+O₄.

Nitronaphthal. C₆H₄N+O₄.

Oxidine. [Phyloline.]

Ganatic Acid, C₆H₄O₄O⁺H₂O, is found in wines in combination with oxide of ethylene, forming an ether, which is one of the elements of the oil of wines. It is also found in the spirit of fermented grain. In order to obtain the acid, the ether is decomposed by caustic potash, and the oxamethane of patah thus formed is distilled with dilute sulphuric acid. The acid thus obtained is a semi-liquid, insoluble in water, but soluble in alcohol and ether. The oxamethane of oxide of ethylene, oxamethanic ether, is a colourless liquid, having the well-known smell of wine, and producing a stupefying effect. This ether has been shown by Mulder to be ferrocyanide of one of many others which give the peculiar odours or bouquet to wines. [Mulder's Chemistry of Wine.]

Ganatlhy, C₄₄H₄₄, is known by some of its compounds.

Hydroxyl Oxide of Brandywine—Ganathile—Ganathile—Ganathile—Ganathile—Ganathile—Ganathile—Ganathile—Ganathile. C₂₀H₁₇O₂+H₂O, is the aldhyde of vanillin acid, and is obtained from castor oil. Ganatnile Acid, C₆H₁₄O₂+H₂O,
is an oily acid, and yields fatty salts. The esteramides of the oxides of ethylene and methyle are fragrant compounds.

Oxyammonium, C₆H₅(NO₃)₂, is obtained from the opianate of ammonia by the loss of one equivalent of ammonia and four of water. It is a pale yellow powder, which, when boiled with water, yields an oil and a salt of methyle.

Oxyammonium, C₆H₁₀(NO₃)₂, is formed from the decomposition of Nocadine, one of the compounds contained in opium. This acid forms soluble and crystallizable salts, with the oxides of the metals and oxides of ethyle. The latter is sparingly soluble in water.

Oxamnine, C₆H₅N₂O₂, is a crystalline compound found in company with narcotine and other compounds in opium.

Oxanthine, C₆H₆(O₃)₂, is formed by the action of nitric acid on narcotine. It crystallizes in fine needles, which are soluble in ether and alcohol and become of a deep purplish black when brought in contact with sulphuric acid.

Oxyne. [Erythric Acid.]

Oxysedonine. [Atumniante.]

Oxalic Acid, C₂O₃N₂H₄, is one of the products of the action of heat on oxalate of ammonia. This acid forms soluble and crystallizable salts, with lime, baryta, ammonia, and oxide of silver.

Palmitic Acid. [Ostle.]

Palmitin, C₁₈H₃₅O₂, a crystalline base discovered by Merck in opium.

Paramide, C₆H₄(NO₃)₂, is formed when mellitate of ammonia is heated in a retort to about 300°C. It is accompanied by another body called Euchronic Acid. Paramide is a solid yellow liquid, which, when boiled with water, is changed into a bimellitate of ammonia.

Paraphenylthalline = Anthracene, C₁₄H₁₀, is a substance polymeric with naphthaline, and also found in coal tar. It melts at 356°C and distils at 359°C, crystallizing in its foliated plates. It has the properties of a number of compounds, in which oxygen is substituted for hydrogen. These compounds are again capable of uniting with hypotonin acid. As with the compounds of naphthaline we are indebted for all that is known of the researches of Laubarn, with a rancid smell. It is a liquid base of low temperatures, and its salts form soap. It forms a Pereloxane of the oxide of ethyle, C₂H₆O⁺⁺ C₂H₄O⁺⁺, which is an oily liquid of a very peculiar smell. It is a compound in the manufacture for giving perfume the Baltimore of the old. It is probable this acid is formed from sugar, as all oily acids are found to be.

Phenyle, C₆H₅H₂O₂, the hypothetical base of carabolic acid, which according to Laurent is an hydrated oxide of Phenyle, C₆H₅O⁺⁺ H₂O⁺⁺. Laurent has succeeded in obtaining with this radical phenylen of a series of compounds resembling those of indigo,osalicylic, and other bodies.

Phthalamide, C₆H₅N₂O₂, is a non-combined compound, crystallizing in silver scales and of a bitter taste, obtained from various species of Phyllorea.

Phlorotina. [Phlophizin.]

Phloridenin. [Phlophizin.]

Phloridzin. [Phlophizin.]

Phloridzin. C₆H₁₀(NO₃)₂, is a substance closely resembling salicine. It is obtained from the roots of the apple, pear, plum, &c., and is extracted in the same way as salicine. It crystallizes in the form of small scales, which are soluble in hot water and in alcohol. It is a very bitter and powerfully febrifuge. When boiled with dilute sulphuric acid, it yields a resinous substance called phlorotine, C₆H₁₀O₂, and grape sugar. If phloridzin moist be exposed to atmospheric air and ammonia it forms a deep red substance, soluble in ammonia, which changes into a white powder by dilution with water. It has the same elements as phlorizin, with eight equivalents of oxygen and two of ammonia. This forms phloridzin.

Phlobaltamide, C₆H₅N₂O₂, is formed from phthalic acid by ammonia.

Phlobaltic Acid, C₆H₅O⁺⁺ + 2HO₂, is formed by the action of nitric acid on chloridate of naphthaline.

Picolin, C₆H₅N⁺⁺, is a volatile oily base, isomer with aniline, and found in coal tar. It has very powerful basic properties, and is the same substance as the odorous described by Unverdorben.

Picric Acid = Carboxylic Acid = Nitroprussic Acid = Nitrophenic Acid, C₆H₅O⁺⁺ H⁺ + HO₂, is formed by the action of nitric acid on anillic acid, indigo, salicine, salicylic, salicylic acid, hydrate of phenyle, common salt, and other substances. However obtained it assumes a crystalline form, and is of a pale yellow or white. It has a very bitter taste, and is said to be habit forming even by adulterating bitter beer. It is fusible and volatile, readily uniting with bases; its salts crystallize and explode when heated.

Picrotin, a bitter principle obtained from the seeds of Mespernum Oculatu (Oculata Indica). It forms white prisms on evaporation, and appears to be a vegetable base containing nitrogen.

Pikryle = Picrine, C₆H₅N⁺⁺ NO₂, is yielded by the distillation of the product obtained by acting on oil of bitter almonds with sulphuret of ammonium. By the action of nitric acid it is converted into trimicropicryle C₄H₆(NO₂)₃.
hydrogen, and sinnamine is left. It forms definite compounds with chlorides of mercury and platinum.

**Syringolamine**, C₈ H₈ O₈, one of the three solids which, according to Kane, exist in tannins, in addition to Erythroline, which is a red fluid. The other solids are Aulosmine and Erythroline.

**Stilbene**, C₆ H₄, one of the products of the decomposition of the compounds of benzoyl. It is formed from the hydrous acid, and is known to be less soluble in water when heated, gives off sulphured hydrogen, and at last distils over, in nearly scales, stilbene. It forms a compound with chloride when this gas is passed through melted stilbene. Bromine combines with stilbene, forming bromide of stilbene, with the addition of nitric acid, nitro-stilbene, nitro-stilbene, and nitrotoluic acid.

**Styracine**, C₆ H₈ O₈, is a substance procured from liquid storax, by distillation with carbonate of soda. At the same time it yields a small quantity of soda and sinnamine, C₆ H₈ O₈. It is probable from this fact that styrole and cinnamole are the same substance. Styracine may be regarded as a compound of cinnamic acid, C₆ H₅ CO, with the oxide of a compound radical, C₆ H₄, which is called styrile. If styracine be heated with a solution of potash, a cinnamate of potash is left, and a hydrated oxide of styrile distils over. This substance exists in two forms, as a solid and as a liquid, and has been described under the name of styrene.

**Syrone**, C₆ H₈ O₄, is a hydrochloric redoubled saccharic acid, which would thus have this formula, C₆ H₈ O₄ + H O. **Sudaminine.** [Jamaic.] **Syrnaptase)** = Emulcin. The white part of both sweet and bitter almonds is principally composed of a peculiar matter very soluble in water, which has been called syriptase by M. Robiquet. It appears to be identical with a substance described by Liebig and Wöhler, and called by them emulcin. Robiquet prepared syrnaptase by submitting sweet almonds, from which all the oil had been expressed, to maceration for two hours, and then subjected them to pressure gradually increased. The filtered liquid holds vegetable albumen in solution which may be thrown down by acetic acid, also gum which may be precipitated with acetate of lead. The sap contains a good deal of acetic acid, sugar and syrnaptase. The lead may be thrown down by sulphured hydrogen, and the sapnaptase by alcohol. The sapnaptase should be washed with alcohol, and dried in ovens over sulphuric acid. The dry sapnaptase is a yellowish white opaque horney mass, which is very soluble in cold water. Iodine produces in the sapnaptase a rose colour. The sapnaptase soon decomposes in solution, deposite a white precipitate, and acquires a mordant colour. It coagulates at 140°C, like albumen. It contains azote and produces ammonia. The analysis of the other parts of the compound, and the properties of this substance by Dr. R. D. Thomson, and Mr. Richardson.

**Carbon** 49.025 48.555
**Hydrogen** 7.788 7.677
**Oxygen** 47.187 47.748
**Nitrogen** 18.910 18.742

100,000 100,000

The action of sapnaptase on the amygdalin of the almond is very singular, and throws light on the way in which the oil of bitter almonds is formed in some of the seeds of the almond-tree. "On mixing a solution of 10 parts of amygdalin in 100 parts of water, a particular decomposition immediately takes place; the mixture becomes clear, without losing its transparency; acquires the odor of bitter almonds, and gives on distillation hydrocyanic acid and hyduret of benzoyl with the vapour of water. The residue is rendered turbid by coagulated sapnaptase, and on continuing the evaporation, a sweet liquid is obtained, which contains crystallisable sugar. After destroying the sugar by fermentation, a fixed acid remains in the residue. The quantity of sugar obtained is more considerable than what the elements contained in the amygdalin produce; it would appear, therefore, that the elements of the amygdalin do not form a volatile combination, but that they form a compound which is not completely unalike the amygdalin and sapnaptase are dissolved in a proper quantity of water; if it is insufficient to dissolve the hyduret of benzoyl, corresponding quantity of amygdalin remains undecomposed. (Traité, p. 576.) The constituents of the bitter almond are the fixed oil, which is separated by expression, and the sapnaptase and amygdalin, the two last in such a condition that they cannot re-set upon each other. When the almond cake is treated with boiling alcohol, the amygdalin is dissolved out, and the sapnaptase coagulated. When the cake is moistened with water, the odours of hydrocyanic acid, and of the essence, are immediately perceived, but the cake must be dissolved in a certain quantity of water, in order that the mutual action of the sapnaptase and amygdalin may be complete, and that the whole of the last may disappear. In preparing the distilled water of bitter almonds of pharmacy, M. Liebig recommends that a mixture of 1 part of the cake and 20 parts of lukewarm water be prepared, and left to itself for twenty-four hours before submitting it to distillation. One atom of amygdalin contains the elements of (Liebig): 1 equiv. of hydrocyanic acid C₆ H₅ N O₅ 2 equiv. of hyduret of benzoyl C₆ H₄ O₅ 2 equiv. of sugar C₆ H₅ O₄ 2 equiv. of formic acid C₆ H₄ O₄ 7 equiv. of water H₂ O

1 equivalent of amygdalin C₁₄ H₂₂ O₈

One hundred parts of amygdalin are said to yield 47 parts of the crude essence of bitter almonds, and these 47 parts to contain 5 6 parts of free hydrocyanic acid. The last acid is not indicated by nitrate of silver added to a solution of the crude essence in water, owing to the presence of the oil; to obtain a precipitate of cyanide of silver, ammonia-nitrate of silver must be used, and the ammonia saturated with nitric acid, "after the manner of time." (Gmelin.)

**Syrningsin, a non-assorted bitter principle, found in the common lilac (Syringa vulgaris).** **Tanacetine, a non-assorted vegetable principle, obtained from the Tanacetum vulgare, the common tansy.**

**Tartaric Acid**, C₄ H₆ O₆, 2 + H O, and Tartaric Acid, C₃ H₆ O₆ + 2 H O, two acids obtained from tartaric acid. By long contact with water their salts are converted into tartar and tartaric acid. **Terophammon**, C₁₀ N H₈ O₈, a compound described by Anderson. It is obtained from norticine by the action of nitric acid of moderate strength. It forms small white crystals, and is sparingly soluble in water. It presents a crimson red colour when heated with sulphuric acid.

**Thiorinnamine**, C₁₀ H₁₄ N₂ S₂. When ammonia is added to the pure oil of mustard, C₁₀ H₁₄ N₂ S₂, this substance is formed. It is crystalline, acts as a powerful base, and yields a variety of interesting compounds. (See oil.)

**Toluise = Tolene, C₆ H₅ H.** This substance, which, according to Deville, is a radical base, is contained in the Balsam of Tolu. It is homologous with benzole. When it is acted on by nitric acid, the hydrogen is replaced by nitric acid, and the molecule is resolved into the styracose and styril, crystalline, are formed. The first is a liquid, and the second is a solid. Other compounds have been produced by Deville. **Toluic acid**, C₆ H₄ O₄, corresponds with benzolic acid.

**Uracil**. [Uryl.] **Uryl, C₆ N₃ H₄ O₄, is the hypothetical base of the various compounds obtained from uric or lithic acid.** This base is also known by the name of Gomysolithic acid, as it contains the elements of 3 equivalents of oxalyl, and 2 of cyanoxy.

The following table will show the relation of this substance to the various compounds derived from uric acid:—

The radical pyridone H₂ O₄, a compound radical not known in its separate state. Its hydrated pyridone vatalor or vataleryduly, is said to be one of the products of the oxidation of ammonia. It is used as a paint in the manufacture of varnish. The pyridone is a volatile hydrocyanic acid when exposed to oxidising agents. It unites with ammonia, forming a crystalline compound with ammonia. **Valerianic acid**, C₅ H₄ O₄ + 4 H O, is found in nature, in the leaves of Valeriana officinalis. It has also been found in train-oil and sperm-oil combined with the oxide of lippyl. It also occurs in various fats and oils from the animal kingdom, and in the seeds of the guelder rose (Viburnum Opulus).

**Vexor of the acida of Bileis** is a fragrant ether, and is

found in plants, giving a peculiar scent to those which possess it. It combines with various other bases. The compounds of valeriy, as far as they are known, are homologous with those of methyl, ethyle, formyl, and acetyl.

Xyloдине, CH₃ (NO₂)₂ O, When potato starch is rubbed up with strong nitric acid, the starch is dissolved, and a viscous liquid is produced from which water precipitates the compound called xyloдине. The same compound is obtained in some of its properties from the bark of the tree, but it contains a large quantity of nitric acid that it is explosive.

The following works may be consulted on the subject of the present state of Organic Chemistry: Gregory’s Hand- book of Chemistry of Organic Compounds, edited by Jones and Hohmann; Lechmann’s Physiological Chemistry, translated by Day for the Cavendish Society; Gmelin’s Handbook of Chemistry, translated by Watts for the Cavendish Society; Bowman’s Medical Chemistry; Turner’s Elements of Chemistry, edited by Liebig; and Graham’s Elements of Chemistry.

CHERT, a variety of quartz being a kind of granular Chaledony. It is a transition from the smoother forms of Quartz to Hornstone. [Atlas.]

CHESHUNT, Herts. [Atlas.]

CHIGWELL. [Atlas.]

CHILDREN, JOHN GEORGE, was born on the 16th of May, 1777, at Ferox Hall, Tonbridge. From the grammar school of that town he went to Eton, and afterwards, in 1794, entered Queen’s College, Cambridge, as fellow-commoner. He studied with a view to the church, but the early death of his wife led him to travel in the south of Europe and in the United States, from whence he returned to devote himself to his profession.

While studying mineralogy, chemistry, and galvanism, he made the acquaintance of Davy, Wollaston, and another leading men of science. In 1807 he was elected a Fellow of the Royal Society, and in 1816 he contributed a paper to the ‘Philosophical Transactions,’ on ‘Some experiments performed with a view to ascertain the most advantageous method of constructing a voltaic apparatus, for the purposes of chemical research,’ in which he determined the effect of unusually large battery plates. With twenty pairs of plates each four feet long and two feet wide, he confirmed Davy’s observation, ‘that intensity increases with the number [of plates], and the quantity of electricity with the extent of the surface.’

This was followed in 1815 by a paper, published also in the ‘Philosophical Transactions,’ ‘An account of some experiments with a large voltaic battery,’ in which a further series of singularly interesting results was described, among them the contact of the zinc with the stone unison with diamond, under the sole action of the battery.

Between the dates of these papers Mr. Children travelled in Spain, and visited the silver mines of Almaden, then but little known in England. In 1816 he was appointed one of the natural history proceed of the Royal Society, and one of the first editors of the ‘Transactions of the Royal Society of Natural History’ of the British Museum. In 1819 he published a translation of Thénard’s ‘Essay on Chemical Analysis,’ and in 1822 of Berzelius’s ‘Treatise on the Use of the Blowpipe,’ with additional experiments and notes. He discovered a method for extracting silver from its ores without amalgamation, and derived considerable profit by selling the right to use it to several South American mining companies in 1834. He helped in establishing the ‘Zoological Society of London’ in 1830, and was one of the first editors.

In 1826 he was elected secretary of the Royal Society, and resigning the following year on account of ill health, was re-elected in 1830, and retained the office for seven years. In 1839, on the death of his third wife, Mr. Children resigned his post at the British Museum. He died on the first day of 1852.

CHINA. In the previous Supplement, under the head China, an account is given of the last war between Great Britain and China, terminated by the Treaty of Nanking in September, 1843, as well as of the events which preceded the war, and the treaties by which it was followed. In 1856 a dispute occurred between the British and Chinese authorities at Canton. A small vessel, not British, which had escaped the French fleet, and bearing the British flag, was boarded by the Chinese, and twelve of the crew were seized. This led to a demand for apology, required by the British plenipotentiary, but refused by Yeh, the Chinese commissioner or governor of Canton. Hostile proceedings followed. The forts in the Canton river were attacked and taken, and a large number of war-junks burned. Lord Elgin was sent out as Her Majesty’s commissioner, with a fleet and troops, for the purpose of entering into negotiations with the Emperor of China. The Chinese, however, sooner or later taking refuge in Hindustan, most of the troops sent from England were required to assist in quelling it, and the quarrel with the Chinese remained unsettled. As however the dispute was not of a nature to authorize there, especially the commissioner, Yeh, the British, attempt to settle themselves with the French, resolved to attack the fortifications of Canton. This operation was successfully performed in the morning of the 29th of December, 1857, when the principal forts of the town were captured, and Yeh’s town of the city were taken possession of. The assault was conducted by Major-General Van Straubenzee, commander-in-chief of the British troops in China, with about 4000 men, assisted by Rear-Admiral Sir Michael Seymour, commander of the British naval forces, and by Rear-Admiral Sir Rignaud de Genouilly, commander of the French naval forces, with about 1500 men. The British and French forces continue to hold possession of Canton. Commissioner Yeh was captured on the 5th of January, 1858, and sent to the Pechino gate.

CHINCHAS, a group of three islands in the Bight of Pisco, on the coast of Peru, lies between 13° and 14° S. lat., 76° and 77° W. long. They are naturally bare rocks, without a sign of vegetation of any sort, but they have obtained great quantities of ashes and cinders, and now they are almost covered. The islands lie nearly north and south, and are separated by channels from one mile to two miles broad. In their general formation they are all alike. On the eastern side they present a perpendicular wall of rock, from the base of which stacks of white and brown cinders (some of them from two and a half to three feet high) project, and form a pinnacled cone, the rocky inequalities of the original surface having been filled up and covered with the cinders, the cuttings of which vary in depth from a hundred feet to a few inches. Round the base of the islands little rocky peninsulas jut out, in which the washing of the ocean has formed many coves, the resort of sea-lobsters. Whales also are frequently seen boiling about the islands. The middle island has been moderately worked, but the greatest quantity of guano has been taken from the north island; the south island is still untouched. The quantity of guano on the three islands has been estimated at 250 millions of tons. Guano is also found on the Battista Islands, and upon San Galleen Island, which lie immediately south of the Chincha Islands. South of the Guano Islands are the Lobos Islands, off the north-west coast of Peru, and at various points along the coast of South America; but what is obtained from the Chincha Islands is prized above all other deposits on account of its extreme dryness. [Guano, S.2] CHICOCOCHA, a genus of plants belonging to the natural order Cichomaceae. Calyx with an oval tube, and an acutely 5-toothed permanent limb. Corolla funnel-shaped, with an obconical tube or throat, and five acute lobes. Stamens with the filaments hardly adnate to the bottom of the corolla, downy, and shorter than the anthers, which are inclosed and linear. Style rather clavate at the apex, entire or slightly 3-lobed. Berry somewhat digitiform, compressed, crowned by the teeth of the calyx, containing two sericeous seeds. Many species of C. coca (from which cocaine), a genus of plants belonging with a long superior radicle. Albumen cartilaginous. Shrub generally with a somewhat climbing habit. Leaves opposite, ovate or oblong acute, glabrous. Stipules broad at the base, permanent, more or less apiculate. Racemes axillary, opposite, simple or paniculate, from the axils of a yellowish-white colour. Roots emetic and alexiartic.

C. racemosa. Racemose Snow-Berry, has oval leaves acuminate at both ends, smooth; stipules broad at the base, the leaf persistent, the flower pedicels short, and the stamens downy. It is a native of the West Indian Islands and Carthagna, on hills. It is a very variable shrub. The corollas at first are white and scentless, but at length become yellowish and sweet-scented. The berries are snow-white, the juice sweetish, the fruit acid, the taste, and has long been used as a strong resolvent or attenuant.

C. densiflora. Dense-Flowered Snow-Berry, has ovate rather coriaceous leaves, many-flowered racemes, the corolla much
CHI

longer than the calyx, the filaments densely-bearded. It is a native of Brazil, in woods at Almeida and Serranas, on the mountains of Bahia, and at the port of St. Catherine.

C. odorata, Sweet-Scented Snow-Berry, has broad oval leaves, rather coriaceous, very blunt, acute at the base, and running down the short petioles; peduncles axillary, solitary; 2-4-flowered. Snow-Berry has a beard of throat. It is a native of Elizabeth Island, one of the Society Islands.

C. bartata, Bearded Flowered Snow-Berry, has oval leaves, acute at the base, and tapering into short petioles, acuminate and obtuse at the apex; peduncles axillary, solitary; 1-2-flowered. It is a native of the Friendly Islands and the Society Islands.

C. javana, Java Snow-Berry, is a parasitical shrub, with oblong lanceolate leaves, acuminate at both ends, glabrous, velvety, and shining above; corysts terminal, trichotonous. This is a native of Java, on the mountains, upon trees.

All the species of Chicoceos grow best in a mixture of loam, peat, and sand, and strike freely in sand under a glass-house.

CHURCH BUILDING COMMISSIONERS were first appointed by the statute 66 Geo. III. c. 45 (which however was for a term of thirty years only) for building new churches in populous districts, and for dividing existing parishes, and assigning new ecclesiastical districts and determining their endowment and patronage, their recommendations being notified and carried into effect by orders in council. In this way, not only have new districts been carved out of existing parishes, and themselves considered as original parishes, but churches and chapels have in some cases been constituted the parish church, and the original parish divided among a district of several chapels of ease.

The ministers of these districts are usually denominatedincumbents, not being parsons and vicars, properly so-called. The Church Building Commission, although by the original Act limited to ten years, was from time to time extended; and by the 19th of Geo. III. c. 39, an act of 1820, it has been transferred to the Ecclesiastical Commissioners.

CINCHOVATINA. [CHEMISTRY, S.1.]

CINNAMODENDRON, a genus of plants referred to Von Martinus’s doubtful order Canellaceae. This genus has been separated from Canella, which is well represented by C. alba, a common West Indian aromatic shrub, with evergreen coriaceous obovate alternate stalked leaves, no stipules, and coryzae of purple flowers. C. alba is often called Wild Cinnamon in the West Indies, on account of its warm aromatic fragrant properties. There is but one other species of Canella. Cinnamodendron has but one species, C. axillare. It is a Brazilian tree with aromatic properties. Its bark is used as a gum and incense. It is administered in low fever and relaxed sore throat.

COCAMAH. [SURREY.]

CLAIR, WILLIAM TIERNEY, a civil engineer, was born at Sion House, Somersetshire, August 23, 1783. He was apprenticed when very young to a millwright in Bristol, and became master of that trade, and several years in that city and at Colebrookdale. In 1806 he removed to the city of Liverpool and entered the service of the late Mr. Rennie as draughtsman; and held the employment till 1811, when he was appointed engineer of the West Middlesex Waterworks. The establishment was at that time on a very small scale—an engine of twenty-horse power supplying the neighbouring hamlets from an insufficient reservoir, yielding no profit to the company. But under Mr. Clark’s advice the works were enlarged, and he spared no exertion to render them complete and effectual, until the power of the mill was increased to 140, and the pumping pumps were 12 sets of pumps, all without an accidental waste of water, and the largest pump could raise 190,000 gallons an hour. Under Mr. Clark’s advice, the company purchased the adjoining land, and erected a new reservoir, which can supply water to 50,000 families, and admit a water pressure of 300 feet, sufficient to reach the upper parts of the town. Mr. Clark, in 1817, built the water works of Mr. Alcock at Stockport, and in 1820, those at the Hove. Mr. Clark was born in 1776, and died in 1842. Mr. Clark was so successful in the art of building reservoirs that he was employed to construct the Thames and Medway Canal, a work which had been stopped for want of capital, and under his direction it was finished some years afterwards; and the great tunnel through the Friesbury Hills, in the Netherlands, was under his personal superintendence. It was the suspension bridge over the Thames at Hammersmith, which was commenced in 1824 and finished in 1827. It is chiefly remarkable for the small deflection of the chains between the chord-line or points of suspension. Mr. Clark was employed by the late Duke of Norfolk to build one over the Arun.

Mr. Clark was however best known by the suspension-bridge which he constructed across the Danube at Pesth. It was begun in 1839 and finished in 1849, at a cost of 622,000 L. At times the bursting of dams and the pressure from accumulated ice in the winter threatened a total stoppage of the works, but all obstacles were overcome by the energy of the master of Mr. Clark, and the bridge remains an admirable monument of his genius and skill.

Mr. Clark was elected a Fellow of the Royal Society in 1857; he was a Fellow also of the Astronomical Society, and a member of the Institution of Civil Engineers. He died September 22, 1852.

CLARKSON, THOMAS, was born March 26, 1760, at Wisbeach, Cambridgeshire, where his father, who was a clergyman, was master of the free grammar school. He was at first educated under his father, and after that was sent to St. Paul's School, London, and thence to St. John's College, Cambridge, where he gained the first prize for a Latin dissertation proposed for the middle bachelors. In the following year, 1785, the Vice-Chancellor of the University announced that the Council had resolved to give Mr. Clarkson, 'Anne lecit invitos in servitum dare' ('I is right to make slaves of others against their will'). The prize was awarded to Clarkson for his essay, which was read with great applause in the Senate House, in June, 1786. He had used much industry in collecting materials for this dissertation, and had become greatly excited by what he had read of the miseries to which the slaves were subjected in the carrying on of the trade. He resolved to use all his efforts to get it discontinued, and he was employed for some time on the subject of the slave-trade, and he was afterwards introduced to Mr. Wilberforce, and other persons of influence. William Penn in 1688 had denounced the trade as cruel, impolitic, and unchristian; in 1727, at a general yearly meeting of the Quakers in London, it was declared "that the importing of negroes is cruel and unjust, and is severely censured by the meeting;" and in 1760 a similar meeting passed a resolution to exclude from their society all who participated in any way in that guilty traffic." While Mr. Wilberforce, seconded by a party which gradually increased, repeatedly brought the question before the House of Commons, Mr. Clarkson was labouring without the walls of parliament, was collecting evidence, writing letters, and attending meetings at Liverpool and Bristol, then the chief centres of the trade, and at Plymouth, Bridgewater, and other places. He even went to Paris, and remained there six months in the greatest heat of the French revolution, furnishing Mirabeau with materials for speeches against the slave trade, which were delivered to the French Convention, but without producing the desired effect. In England, however, after more than twenty years of incessant exertion, the cause was won: a law for the entire abolition of the trade in slaves was passed March 25, 1807, Mr. Wilberforce having first brought the subject before parliament in 1779.

But the exertions of Clarkson and his supporters, who had now become numerous, did not terminate with the suppression of the trade in slaves. The struggle was afterwards continued during another twenty years for the total abolition
of slavery in the British West India Islands. In 1833 their efforts were again crowned with success, by the passing of the Emancipation Act, which effectually emancipated the slaves, and awarded twenty millions of pounds sterling as compensation to their late owners. Declining health had prevented Clarkson from appearing in public during the latter years of the movement. Catarrh had formed in both of his eyes, and for a short time he was quite blind. He underwent an operation which completely restored his sight, and in 1840 he made his last public appearance at a meeting of the Anti-Slavery Convention at Exeter Hall, over which the Duke of Wellington presided. The meeting was unanimously acknowledged, and he was enthusiastically greeted as the patriarch of the cause. He died at his residence, Playford Hall, Sussex, September 26, 1846, at the age of eighty-four.

Besides several pamphlets and other small works, all bearing more or less directly on the one great object to which he had devoted his life, Mr. Clarkson published, in 1806, 'A Portraiture of Quakerism,' 3 vols. 8vo; in 1808, 'The History of the Abolition of the Slave Trade,' 2 vols. 8vo; in 1818, 'Memoirs of the Public and Private Life of William Penn,' 2 vols. 8vo; and in 1836, 'Researches, Antediluvian, Patriarchal, and Historical,' 8vo.

(Thomas Taylor, Biographical Sketch of Thomas Clarkson; Geddes, Memoir of Unwin.}

CLARY. [Galv.]

CLAY, HENRY, was born in Hanover county, Virginia, April 12, 1777. He was the seventh son of a clergyman, who had been a member of the society. Clay was very young, leaving his wife and family but something to run the school of a common school education, Henry obtained a situation as copying clerk in the chancery court of Richmond. Here he probably received a certain amount of initiation in legal proceedings, so that although he was nineteen years of age when he formally commenced the study of the law, he was only twice admitted to practice at the bar. The tide of migration was then setting strongly westward, and the young advocate thought that the fertile valleys of the west offered a fairer field for his profession. He accordingly removed to Lexington in Kentucky, and there, in October 1799, he fairly commenced his legal career. As an advocate he quickly achieved a marked success. Young Clay, it was soon seen, not only possessed great natural ability and doubted its value by constant diligence, but had the more marketable talent of knowing how to manage a jury. Yet though he found himself on the road to fortune, his ambition was directed rather towards political than professional advancement. The people of Kentucky no doubt saw in him a man fit for the state of Kentucky soon afforded him the opportunity he desired of taking a prominent part in political movements. His advocacy of a provision for the gradual abolition of slavery entailed on him some temporary unpopularity, but his subsequent course of events showed the people of Kentucky were regarded as an encroachment on the part of the central government, and he was at the next election (1803) returned to the state legislature.

His political career was now fairly begun, and for nearly fifty years his life may be said to have been devoted to the service of his country. His first election to Congress was in 1806, but it was only for the remaining portion of a term; and in 1807 he was again elected to the General Assembly of Kentucky, of which he was chosen speaker; an office he held till he was in 1809 elected for an unexpired term of two years to the senate of the United States. In 1811 he was sent as a representative to Congress, and on the meeting of the house, he was elected by it to the chairmanship. The remarkable honour of being elected speaker, though he was now for the first time a member of the house. But his speeches in the senate, and his conduct as speaker of the Kentucky Assembly, had established his reputation; and so well satisfied were the members with their choice, that he was five times re-elected speaker. During this period he took a prominent part in the great questions of the day, but especially distinguished himself by his earnest denunciations of the English claims to right of search and other maritime pretensions. It was the war of 1812, and the efforts of the commissioners to negotiate the treaty of peace. On his return to America he was at once re-elected to Congress.
was wanting in comprehensiveness. His views were at best too strictly national, and, as in the case of the protective tariff, and in his general foreign policy, he too readily took for granted that what seemed to give an advantage to his countrymen was really for their benefit in the large view of things.

CLINKSTONE, a grayish blue rock, consisting principally of Felspar. It passes gradually into gray basalt, but is distinguished from that rock by its lower specific gravity. When weathered it becomes a sage like stone, and is frequent in volcanic districts. It is also called Phonolite.

CLINTON, HENRY FYNES, was born January 14, 1781, at Gamston in Nottinghamshire. He was the eldest son of the Rev. Charles Fynes Clinton, D.D., prebendary of Wykeham, and was educated at St. John's College, Cambridge, and was descended in direct line from Henry, second earl of Lincoln. The family name was Fynes till his father obtained a royal licence, April 26, 1811, to resume the ancient family name of Clinton.

Mr. Clinton was educated at Southwell School, Nottinghamshire, where he remained from 1769 till 1796, and was well grounded in the classical language. In September 1796 he was removed to Westminster School, where he remained till Easter 1798, not on the foundation. In April 1799 he went to Oxford, where he was entered a commoner of Christ Church, and remained till 1806. He graduated B.A. in 1803, and M.A. in 1805.

At the general election of 1806 he was returned M.P. for Aylesbury, and was elected to the chair of the Duke of Newcastle, and continued to be one of the representatives of that borough till the dissolution of 1826, after which he was succeeded in his seat by his next brother. He was diligent in his parliamentary attendance, but was not a speaker. In his politics he was a Whig. He died, the death of Dr. Planta, in December 1857, he was a candidate for the office of principal librarian of the British Museum; but the claims of Sir Henry Ellis from long service and experience determined the choice of the Marquis of Lansdowne, then Home Secretary, in his favour. Mr. Clinton inherited an ample fortune from a distant relative. He died at his residence, Welwyn, Hertfordshire, October 24, 1852.

Mr. Clinton married June 22, 1809, but his wife died February 1810. He married January 6, 1813, a daughter of Dr. Majendie, bishop of Bangor, who survived him, together with eight daughters. His only son, Charles Francis Clinton, graduated B.A. of Christ Church, Oxford, in 1836, served in Spain in the Christino army, was decorated with the Cross of San Fernando by Espartero, was appointed in 1843 British ambassador under the treaty with Portugal for the abolition of slavery, and died at Leonde, on the west coast of Africa, in 1844.

Mr. Clinton was, in his time, a classical scholar of the highest class. He read carefully all the best works of the Greek and Roman writers with a diligence perhaps unexampled, at least in modern times. He himself states, that while at Oxford, during less than seven years, he read 5223 pages of the Greek poets and historians. But a few days after his graduation in 1803, he read about 40,000 pages: he used to read at Oxford amounting to 746 pages annually, while the reading during 1810-20 amounts to 4000 pages annually, which is at any rate more than five times greater.

Mr. Clinton's two great works, the 'Fasti Hellenici' and 'Fasti Romani,' have a European reputation, and are literary works of which every classical scholar of Great Britain may well be proud. The 'Fasti Hellenici' (the 'Civil and Literary Chronology of Greece and Constantinople,' 2 vols. 4to, Oxford, 1818-1820) was published in 1818, and was published in four separate volumes in 1824, 1827, 1830, and 1834; but the work is now divided into 3vols., which are sold separately—vol. i. extending from the earliest accounts to the 5th Olympiad, vol. ii. from the 5th to the 24th Olympiad, and vol. iii. from the 24th to the 41st classical Olympiads, the death of Augustus. Besides the chronological tables, of which these volumes for the most part consist, they are interspersed with dissertations on the early inhabitants of Greece, the different periods of the early history, the Ephesus chronicle, the writings of Homer, the population of ancient Greece, and other interesting subjects. The 'Fasti Romani' (the 'Civil and Literary Chronology of Rome and Constantinople, from the Death of Augustus to the Death of Heracleus'), 2 vols. 4to, Oxford, 1836, was published in 1836, and in 1838 and 1839. It was published as 'An Epitome of the Civil and Literary Chronology of Greece, from the Earliest Accounts to the Death of Augustus,' 8vo, Oxford; and in 1853 appeared 'An Epitome of the Civil and Literary Chronology of Rome and Constantinople, from the Death of Augustus to the Death of Hercules,' 8vo, Oxford; two abridgments which are very useful to those students who cannot afford to purchase the larger and more expensive works.

(Clownes, [Magazine.])

CLOWES, WILLIAM, printer, was born at Chichester, January 14, 1738, and January 23, 1814. He was apprenticed to Mr. Clowes was educated at Oxford, and kept a large school at Chichester; but he died when the subject of this notice was an infant, leaving his widow to support two children with strained means. She was enabled, by keeping a small printing-office for the lyceum and the school, to support herself and apprenticed to Mr. Seagrave, a printer at Chichester. He came to London in 1802, and worked as a compositor with Mr. Teape, of Tower Hill. In 1803 he commenced business on his own account in Villiers-street, Strand, on a capital of £300. He purchased one press, engaged one comestant; and, after working as a compositor through the day, would often, for two or three consecutive nights, till press, to have his stock of type free for the next day's demand. It was this energy of character that raised Mr. Clowes to his subsequent eminence. Fortune favoured his exertions. He married when he was at the age of twenty-four, a cousin of Mr. Winchester, a stationer, who had much government business; and by him he was recommended for important official work. He was appointed printer to the new government, and brought friends around him; and in a few years the humble beginner with one press had a considerable printing-office in Northumberland Court, Strand. This office was burnt down; but a larger rose in its place. In 1823 he commenced business in Fetter-lane, where his press was in a dark cell: and, the process being novel, his office had many visitors of literary reputation. Mr. Clowes was always a signal example for the honest arbour of manufacturing enterprise to lead the way under new circumstances. In 1829 the newspapers were printed by steam; and he estimated the possibility that books might be demanded in sufficiently large numbers to make the new invention of more universal application than was at first considered probable. An action brought by the Duke of Northumberland, whose palace was close to Mr. Clowes's printing-office, to abate the steam-press as a nuisance, was successfully defended; but the printer removed his noise and his dirt, under the award of arbitrators; and the decision was a fortunate and timely precedent, as it became the occupier of the spacious and well-known premises in Duke-street. Stamford-street. In the course of years the humble establishment of the young Sussex compositor grew into 24 steam-presses and 28 hand-presses, giving employment to 300 workmen, the most efficient, most economical, and well-ordered printing manufactory that had ever existed in the world. The creation of literature that should at once reconcile the apparently dissimilar qualities of goodness and cheapness, through a demand for books before unprecedented, gave a decided and permanent stamp to the book trade. It was published as 'The Penny Cyclopedia' and 'The Penny Cyclopaedia' issued with undeviating regularity for fourteen years from his printing-office. Mr. Clowes was not a common man. His powers of arrangement were most acute; he was at once bold and prudent. He was one of those few men who would not recognize the word 'impossible' as one to be lightly employed. He who in 1803 had a few hundred weight of type to be worked from day to day like a banker's gold, would not hesitate, in 1850, to print a roll or monthly paper, requiring 800,000 pounds sterling, give employment to 2000 workmen, and lock up for months in some ponderous blue-book. To print an official Report of a hundred folio pages in a day or night, or of a thousand pages in a week, was no uncommon occurrence. Mr. Clowes's name will not be associated with the highest class of literary publishing; his was another ambition. He lived in an age when knowledge was to become the inheritance of the many; and he furnished the means of carrying out this literary revolution in a more efficient manner than had ever before been known. He was the first to be permanently associated with the intellectual development of our time. (National Cyclopaedia.)

CLOUGH, a name given to the lower and harder beds of the Cretaceous Rocks. They are occasionally used for the manufacturing of flints and glass, and as a manure. There is internal work in cathedrals and other large public buildings. This material stands well if not exposed to accidents from mechanical violence. (Annoted, Elementary Geology.)
it leaves an ash which consists of varying quantities of silica, alumina, and oxides of iron. The carbon and hydrogen are often found chemically united to form bisulfurous compounds which are mixed with the coal. It is the presence of these compounds which causes coal to burn with a bright flame; at the same time they give off a bituminous odor. Those kinds of bituminous coals are known as having a pale blue flame, due to carbonic oxide, which is formed in these coals through the decomposition of the water present.

The following table, founded on Mr. Muschet's Analysis of Coal, is taken from Professor Ansted's 'Elementary Course of Geology, Mineralogy, and Physical Geography':

**Analysis of various kinds of Coal.**

The Torbane mineral is only remarkable among other coals for the large quantity of sulphur it contains.

A large series of coals, more especially Welsh, has been submitted to chemical examination by order of the government; and the following table is taken from the 'Report on the Coals suited to the Steam Navy,' by Sir Henry De la Beche and Dr. Lyon Playfair, in the second volume of the 'Memoirs of the Geological Survey of Great Britain':

for making inkstands, snuff-boxes, and other articles of use.

The above coals are those most commonly burned.

Common Scotch Bituminous Coal. 6 lb.
Carr's West Hartley Main (Newcastle). 6 lb.
Merthyr Bituminous Coal. 6 lb.
Pare Welch Anthracite. 6 lb.

Brown Coal, Wood Coal, Lignite, are names given to less perfect varieties than the last. Specimens of these coals have a brownish-black colour, and burn with an empyreumatic odour.

On placing sections of Lignite under the microscope, the structure of the wood of the plant forming it can be readily detected. This is not the case with the other kinds of coal, where, although the woody fibre can be frequently made out, it has evidently undergone considerable change. Power and Quetke, in their account of the formation of coal, have indicated the term lignite to those mineral substances which are evidently made up of the woody tissue of plants. He maintained that the Torbane mineral was not coal, on the ground that it was not composed of the debris of remains of vegetable tissues. Although woody and vascular tissue can be seen in the Torbane mineral, Professor Quetke maintains that this has been accidentally introduced, and that no true vascular or spiral tissue is found in coal.

Dyestill is a yellow or grayish highly laminated substance, often found with lignite, and burning vividly, and spreading an odour of asafetida." (Anecd.)

Jet is another variety of coal belonging to the bituminous sub-class, occurring in various uniform masses, and sometimes in the form of branches with woody structure. It is soft and brittle, with a conchoidal fracture. Its specific gravity is but little greater than that of water. It is operable by various cutters and hammers. It is known as jet. It is found in Saxony, and also in the Prussian amber mines in detached fragments. It is sometimes washed up on the shores of Great Britain. The finer sorts are used in the manufacture of ornaments and trinkets of various kinds. The coarser sorts are burnt as fuel. It is found when burning a greenish flame and a strong bituminous smell, and leaves a yellowish ash. It contains about 37% per cent. of vol. tile matter.

For an account of the origin of Coal, and the beds of Coal on the surface of the earth, see Coal Formation and Coal Plants.

**COC**
for reconciling Spain and her transatlantic colonies. He was conspicuous in the hostilities in America in 1813 and 1814, and was present, as a member of the legislative council of the navy, at the Battle of the Nile, July 1, 1798, and the Battle of Trafalgar. For his services in this victory he was rewarded by a gold medal. He was appointed, in 1805, a captain of the Orinoco, and, in 1806, to the command of the Blake, 74, in which ship he sailed under Lord Gardner in the expedition to Walcheren, and was thanked for his services in forcing the Scilde, in August 1809. In 1810, 1811, and 1812, Captain Codrington was employed in the defence of Cadiz and Tarragona, and in co-operating with the Spanish patriots in Catalonia. In January 1813 he returned to England.

In 1814 Captain Codrington sailed to North America, and while there was promoted to the rank of rear-admiral, and was appointed captain of the fleet under Sir Alexander Cochrane. He took part in the attack on New Orleans. At the conclusion of the war with the United States he returned to England, and was placed in the commands of the Bath, January 2, 1815. He attained the rank of vice-admiral July 10, 1821.

Sir Edward Codrington was appointed, November 1, 1826, commander-in-chief of a squadron in the Mediterranean destinied to observe the Turkish Mediterranean fleet, and hoisted his flag on board the Asia, 84. He was joined by a French and a Russian squadron, and the battle of Navarino took place October 23, 1827; when the Turco-Egyptian fleet, consisting of 61 ships, was completely and almost entirely destroyed. For his services he was appointed an "unequivocal" baronet, with the dignity of knight grand cross of the Bath; but as there was much doubt among politicians as to the propriety of destroying this fleet, and the Duke of Wellington admitted that it was not a "Sir Edward Codrington's piece of work, the achievement was in a manner veiled from the Mediterranean in April 1828. In 1833 he was elected M.P. for the borough of Devonport, and was re-elected in 1835, and again in 1837. He was of liberal politics, and very popular. In 1827 he attained the full rank of admiral, and on the 22d of November 1839, was appointed first vice-admiral, and commanded the Mediterranean fleet. He was an active friend of the anti-slave-trade movement, and was its strongest advocate in the House of Commons.

CELEBOYNE, a genus of plants belonging to the natural order Euphorbiaceae. This genus was named by Mr. J. Smith from a specimen grown in the Royal Gardens at Kew. It is remarkable for the fact that the blossoms, which are pinnate, have ripened their fruit and produced seeds containing a perfect embryo without the presence of the staminate flowers. This appears to be quite an exceptional case to the law of production of the embryo by the agency of the female or staminipetalous flower. Further observation may detect some hitherto undiscovered means by which the pollen-cells of perhaps a allied plant may come in contact with the pistil of the Celebogyne.

COGGESHALL [Essex].

COBLY, THOMAS, Major-General in the army, and one of the Directors of the Ordnance Survey, was born at Rochester, Ist of September 1784. When his father, Captain Cobly, of the Royal Marines, sailed with the fleet under Lord Howe, he was sent to Dr. Crockell's school at Northfleet, and from thence he entered the Royal Military Academy at Woolwich. He obtained his first commission as second lieutenant of engineers in 1801, being then but seventeen years of age. His diligence and success in scientific study were such that in January of the following year, at the special request of Captain Mudge, then superintendent of the ordnance survey, he was appointed one of the assistants in that great work. Entering at once on his duties, he justified the expectations formed of him, by the intelligence and conscientious activity which he brought to the work of surveying. He was on a tour of inspection in Cornwall, in 1803, when he lost his left hand by the bursting of an old pistol, and suffered at the same time a fracture of the first and third fingers, which he traces to the accident of a fragment of the barrel, that he felt the effects of the accident for the rest of his life whenever he attempted any long-continued mental exertion. Though the loss of his hand and the loss of his flag-ship, the loss of the Hibernia, which Captain Mudge was so well satisfied of his merits, that he kept the young lieutenant permanently attached to the survey.

In 1805 Lieutenant Cobly was observing at Dunmore, one of the prominent points of the survey: in 1804 at Beaumaris; and in 1806 with the seigneur sector at Burleigh Moor and Delamere Forest. The winter months he passed in the
C O L

'Drawing Room' at the Tower, computing and preparing the results for publication, and superintending the construction of the ordnance maps on a scale of ten feet to the mile. So thoroughly was he identified with that great national work, that the history of one becomes in great measure the history of the other. In 1807 Colby was promoted to the rank of captain. The third volume of 'An Accurate Description of the British and Irish Coast' was published in 1811, and his name appearing jointly with that of Colonel Mudge on the title-page, showed how highly his services had been appreciated by his chief. In 1815 it was determined to extend the meridian line of Scotland, a work which called out in an especial manner the energies for which Captain Colby was remarkable. Within the next three years he visited and observed at the principal stations beyond the Tweed, besides attending to his official business at the principal observatories. The surveying, levelling and other work required for a season of observation on the hills would appear incredible to one unacquainted with the nature of the work. Besides the mental exercise of keeping all the subordinates to their duty, so as to produce harmony in the results, there was much personal fatigue to be endured in long walks over the country, together with storms and wearisome delays on the mountain tops. But with Captain Colby duty was paramount, and he cared not for privation, so that the work was performed with great success. In his account of the Season on the Hills' gives a striking picture of the toils and hardships experienced: "It was no uncommon occurrence, he remarks, "for the camp to be enveloped in clouds for several weeks together, without affording even a glimpse of the sun or the stars of the heavens. And then the moment the clouds would break away or subside into the valleys, leaving the tips of the mountains clear and bright above an ocean of mist, and the atmosphere calm and steady, so as to admit of the observations for which the party had waited days and weeks to be taken in a few hours." At times the tents would be blown down by storms—or the camps would be whitened by a fall of hail or snow in July: or the captain taking two or three of the junior officers and a few men without starting on a trip, would start on a course by compass for the peaks that seemed most suitable, regardless of the nature of the intervening country. In these explorations they walked from thirty to forty miles a day, wading streams, crossing bogs, scaling cliffs, and sliding down into rocky valleys, Captain Colby ever the foremost; and when they came to a summit which his experience told him was suitable for a station, he would help with his own hand in building up the great pile of stones by which it was to be distinguished from all other points. Some of the times the resting-place at night would be a miserable hovel where no other food was to be obtained than the national porridge; at others the weary explorers rested under a ducal roof, or at the base of the mountain during the hot months they were tormented and blistered by the unbearable midges.

In one trip in 1819 the party walked 586 miles in twenty-two days. From this brief summary, a notion may be formed of the severe labour of the survey, apart from the scientific duty of observing with the instruments, which on all favourable occasions was continued from sunrise to sunset.

Captain Colby's activity and kindness of disposition were not less apparent in camp than on the station-hunts. He would settle in erecting houses to "shelter the soldiers; and occasionally join with the men in a game of quoits, or in putting the stone or crowbar, and was a warm promoter of their feast at the close of each trigonometrical season." He was quite indifferent as to personal fame, but not so as to make himself contemptible. On one occasion, when I was on leave, he permitted them to publish portions of the work in their own names rather as principals than assistants. His command over his temper was perfect; but he disliked to be disturbed by curiosity when busy with observations for which he had long waited the opportunity. Once, while encamped on Slieve Donard in Ireland, the summit of Sea Fell in Cumberland became visible at the distance of 111 miles, and after many trials the instrument was brought to bear upon it. "Oh! Colby," exclaimed one of his officers, "now is the time for observing, which would have been a geodetical triumph, as including the longest side of a triangle ever attempted, when an officer on entering the observatory accidentally struck his elbow, and threw the telescope off the object. A momentary eruption escaped his lips, but not again succeed, and the object was therefore lost, he never afterwards alluded to the subject."

He was one of the party that accompanied Biot on his trip to Shetland in 1817, when, in compliance with the request of the friends of their country. Wharram, he was permitted to observe on the line of the English arc. A coolness however arose between Biot and Colby, and while the latter, undeterred by fog or storm, made his observations with the sector on the rock of Balta, the former climbed to the summit of Uist selected by Colby afterwards assisted in connecting the French with the English triangulation by the observations across the straits of Dovers.

In 1829 Captain Colby was elected a Fellow of the Royal Society; he took an active part in establishing the Astronomical Society; and General Mudge having died, he was appointed his successor as superintendent of the Survey, and in the Board of Longitude. In 1821 he was promoted to the rank of lieutenant-colonel, and received a grant of a hundred and forty acres of land near his beloved home, the county of Ireland. In this work the usual mode of proceeding was modified: the survey was made dependent on actual measurements with the chain, with a trigonometrical point fixed for every 400 acres; and the whole series of operations was so ably combined that one party was usually a check on the other, and the utmost accuracy was arrived at, although the number of persons employed exceeded two thousand, mostly from the native peasantry. A change was also made in the methods of levelling; the level was not made to correspond to the mile, all the principal farms, fields, and inclosures being represented, so that the maps have ever since been regarded by the government, land-proprietors, and surveyors, as authentic plans of all the estates in the country. Poorer and more uninteresting works, the Irish census, have all been based upon them. They are comprised in 1839 sheets.

In 1835 Major Colby became lieutenant-colonel, and in that year he obtained the Duke of Wellington's sanction for raising and training three companies of provers and masons to aid in the Irish survey, as the want of really efficient assistants was felt at first as a serious hindrance to the progress of the work. In the course of the operations Colby made the acquaintance of Joseph Lough Foyle, with 'compensation-bars' which he had himself invented. He had carried on a series of experiments on the heating and cooling of metal rods, and he succeeded in constructing a bar of brass and iron in combination, the extremities of which remained always the same distance apart whatever might be the temperature. Such is the exactitude obtained with this apparatus that it has since been used in measuring a base of eight miles at the Cape of Good Hope, for determining the position of ships lying in ports, and in those required for the great arc of the meridian in India.

In 1838 Colonel Colby resumed the triangulation of Scotland, which had been suspended; and from this date up to his promotion to the grade of major-general in 1846, when he relinquished the service his connection with it by the science of surveying and trigonometry. His survey ceased, he continued his usual active and energetic superintendence of the various operations. He brought the engraving of the English maps to an excellence never before achieved. The second of the national atlases was marked on the margins, and he co-operated with Sir Henry De la Beche in introducing the geological facts and features which have since become so important a part of the survey. He took the necessary measures for a series of tidal observations round the coast of Ireland, for the purpose of establishing a true datum level: "the most important series of tide-observations," says the astronomer-royal, "that has ever been made."

"All his scientific career General Colby never sacrificed duty to selfish considerations; and his rare administrative abilities, and sound judgment combined with high principle, enabled him to accomplish well all that he undertook. He had resources ready for every emergency, and his perseverance triumphed over all obstacles. He died in Liverpool on the 9th of October 1862, leaving a widow and seven children. He was a fellow of the chief scientific societies of London, Edinburgh, and Dublin; LL.D. of Aberdeen, and a knight of the post-town of Coleseraine; a sea-port and post-town, a municipal

C O L

COLEMAN, county of Londonderry, Ireland; partly in the parish of Coleseraine. It is about a mile from the barony of Coleseraine, situated in the parish of Coleseraine and Coleraine, and is at the north-east liberties of Coleseraine; a sea-port and post-town, a municipal
and parliamentary borough, and the seat of a Poor-Law Union, is distant 145 miles N. from Dublin. The population in 1851 was 6990, exclusive of 242 inmates of the Union workhouse. The town was an early-day-drug centre and market to the Imperial Parliament. The paviing, lighting, &c., of the town are under the care of 21 town commissioners. Coleraine Poor-Law Union comprises 20 electoral divisions, with an area of 115,970 acres, of which 12,160 acres are watered.

Coleraine is situated on both banks of the river Bann, at a distance of 4 miles from the sea. The principal part of the town is on the right bank, and consists of a central square called the Diamond, with several leading streets diverging from it. The town is watered by the Bann and its various suburbs. The suburbs of Killowen or Waterside on the left bank of the River Bann is a stone structure of three arches, 288 feet long and 32 feet in breadth, erected at a cost of 14,000l. There is a great thoroughfare in this road to Portrush and other parts of the north of Ireland, the road to Antrim and Londonderry. The parochial churches of Killowen and Coleraine stand in the respective divisions on either side of the river. There are also two Roman Catholic chapels and six meeting-houses of various denominations of Dissenters, an Endowed school, a National Model school, and a savings bank. The old court-house and town-hall stands in the centre of the Diamond. There is a new market-place with a commodious market-house. The town is lighted with gas. Vessels of 500 tons burden can accommodate a passenger. The trade of Cokeraine is conducted from the harbour of Portrush 5 miles distant on the coast near the embouchure of the river. At Portrush is a harbour formed by two piers of 600 feet each and a breakwater 2000 feet long, with a breadth of 300 feet at low water, with an area of 4 acres, with from 15 feet to 20 feet of water at the wharves. The customs duties of the Cokeraine district in 1856 amounted to 40,000l.; the excise duties amounted to 40,644l. The number and tonnage of vessels belonging to the port in 1856 were ten vessels of 233 tons aggregate burden. The entries and clearances at the port in the coasting and cross-channel trade in 1856 were:—Sailing vessels, inwards 120, tonnage 6000; outwards 44, tonnage 1365: steam vessels, inwards 121, tonnage 24,906; outwards 51, tonnage 1,125. The total number of passengers in 1856 was 5619, and cleared 4 vessels of 1790 tons. The principal trade is the manufacture and bleaching of linens and the salmon-fishery. A fine description of linen manufactured here is known as 'Coleraine.' The annual sales of linens are estimated at 600,000l. The fisheries of salmon and eel are the property of the Irish Society, who farm them out at an annual rent of 1200l. Upwards of 300 persons are employed as water-bailiffs in the protection of the salmon fishery.

Coleraine in the Presbyterian Church arrangement is the seat of a Presbytery of the General Assembly, consisting of 16 congregations.

Coleraine is remarkable in early Irish history as the place in which Patrick found a Christian bishop already located on his first progress through the northern parts of Ireland. A castle was built here in 1213 by Thomas Mac Uachtred, a Scottish adventurer. One of De Courcy's followers, called De Sendall, also erected a castle very soon after the conquest. The present town stands on the site selected by the Irish Society in 1613. It was at first fortified by an earthen wall with bastions. The place held out against the rebels in 1641. In 1653, the whole customs of the port amounted to only 116ls. 9s. 4d. The neighbourhood is rich and well cultivated. A fall of the Bann over a ledge of rock of 12 feet high, at the Cutts, about a mile above the town, adds considerably to the picturesque interpolation of the environs.

CORDERIE and PARTLY, in 1619, the eldest son of Samuel Taylor Coleridge, was born at Cledenon, near Bristol, Sept. 19th, 1796. Two sons of his father are commemorative of his birth; and an exquisite poem of Wordsworth, 'The Cauterizing potions' appear in this number of the West--"whose fancies from afar are brought." His infancy is also associated with two poems of his father, ' Frost at Midnight,' and 'The Nightingale.' In 1800 S. T. Coleridge went to reside in the Cumberland Lake district; and there Hartley was reared; having a brother, Derwent, four years younger than himself, and a sister, Sara, six years younger. He was taken to London in 1807; and the various sights which he saw made an indelible impression on his mind, the effect being immediately apparent in the composition of those extraordinary day-dreams which afterwards formed the first part of the "Christabel." In 1808 he was placed, as also his brother Derwent, as day-scholar of the Rev. John Dawes, at Ambleside. As a school-boy his powers as a story-teller were unique; his imitations were original and ingenious; his imagination was enormous; his work was night after night for a space of years. During their school-days, the boys had constant intercourse with Mr. Wordsworth and his family; and Hartley made the acquaintance of Professor Wilson, who was his friend through life. His friendship with the Wordsworths continued "—by the living voice of Coleridge, Soutey, and Wordsworth, Lloyd, Wilson, and De Quincey." In 1814 Hartley left school; and in 1815 went to Oxford, as a scholar of Merton College. His extraordinary powers as a converser, and his numerous invitations to wine-parties, were injurious to him in two ways—he used great freedom of remark upon "all establishments," and he acquired habits over which he had little subsequent power of control. He passed his examination for his degree in 1816; he then studied for a fellowship at Oriel, with high distinction. An unhappy issue followed this honourable and independent position. "At the close of his probationary year, he was judged to have forfeited his Oriel fellowship, on the ground, mainly, of his imprudence in his conversation and habits. He had no record that any friend stepped in to rescue one, so otherwise blameless, so sensitive, so unfit for any worldly struggle, from the permanent consequences of this early error. He never got back to college life, with a manly and touching sincerity says, 'As too often happens, the ruin of his fortunes served but to increase the weakness which had caused their overthrow.' It is unnecessary for us to follow the biographer's explanation of some of the causes which led to this unlooked-for—his mother's consciousness of his own singularity—his despondency at being unsuccessful in obtaining University prizes—his incapacity for the government of the pupils whom he received while at college on his incompetence of control, and a belief that he was watched by those with whom he was destined to have the most unintelligible manifestations of his peculiar temperament. His qualification for future active exertion was irrevocably destroyed. After leaving Oxford, Hartley Coleridge remained in London two years, occasionally writing in the 'London Magazine,' in which some of his sonnets first appeared. Against his will he was established at Ambleside to receive pupils. The scheme failed; and after a vain struggle of four or five years, the attempt to do what he was unfit for was abandoned. Three years of life from that time were spent in the Lake district—idle, according to ordinary notions, but a diligent reader, a deep thinker, and a writer of exquisite verses, and of prose of even a rarer order of merit. From 1833 to 1836—he resided at Ambleside; and again, in 1838 and 1839 he resided with Mr. Bingley, a youngprinter and publisher at Leeds; for whom he produced a volume of 'Poems,' and those admirable biographies of the 'Worthies of Yorkshire and Lancashire,' which make us more than ever regret that one who wrote with such ease and vivacity, should have accomplished so little. In 1834 his father died, having, in a codicil to his will, expressed great solicitude to ensure for his son that "tranquillity indispensable to any continued and successful exertion of his literary talents," by providing for him, through the proper application of a bequest after the death of his mother, "the continued means of a home." Mrs. Coleridge died in 1846, and an annuity was then purchased on Hartley's life. Meanwhile, he lived with his humble family, first at Grasmere, and then at Hydal Water, washed over by the kind people with whom he was an in-mate, and beloved by all the inhabitants of the district. His illustrious friend Wordsworth was his close neighbour; and the house of the poet was always open to the child-like man of whose verse his father had been almost prophet. In 1839 Hartley wrote a life of Massinger, prefixed to an edition of his works published by Mr. Moxon; and during the latter years of his life he wrote many short poems, which appeared in the 'Leeds Intelligencer,' and in a 'Memorial of His Life,' in 1851. Hartley Coleridge died in the cottage which he had long occupied on the bank of Hydal Water, on the 6th of January 1849; and was buried in Grasmere churchyard. His grave is by the side of that of Wordsworth.

COLERIDGE, SARAH, the only daughter of Samuel Taylor Coleridge, was born at Ambleside, on the 7th of August 1811. She was educated with her four sisters, at Miss dood in Grasmere, and Miss Lea in nearby Ambleside. She later attended a private school in London, where she met her future husband, Henry Hartley. She returned to Ambleside with her husband after his death in 1849. She was a member of the literary circle that included Samuel Taylor Coleridge, Robert Southey, and William Wordsworth. She contributed to the 'Leeds Intelligencer' and had a personal correspondence with Thomas Carlyle. She died in 1895 and is buried in Ambleside churchyard.
COL

Coleridge was born at Keswick in 1803. Until her marriage as a result of the influence of Robert Southey, who married her mother's sister. To his influence must be ascribed the formation of her mental character must be largely ascribed, though she possessed in a remarkable measure the intellectual characteris- tics of her father. Her opening womanhood was spent at Keswick in the delightful scenery and exercise of her remarkable powers. She readily lent her assistance to Southey in lightening as far as she could his literary labours: she often accompanied Wordsworth in his mountain rambles. In 1822 she had completed her first literary work, 'An Account of the Aborigines of New South Wales,' prefixed to the Latin of Martin Dohrzesoff, a translation suggested by Southey, and the admirable execution of which he has commemorated in a stanza of his 'Tales of Paraguay.' In 1829 she married her cousin, Henry Nelson Coleridge. [Corrections]

She now gave herself to her domestic duties, and her next literary production was prepared as a Latin lesson-book for children, 'Pretty Lessons for Good Children,' and speedily passed through several editions. On the death of her father in 1834, her husband, who was the poet's literary executor, set himself to the task of preparing much of the poet's unpublished works as would best exhibit him to a theologian, philanthropist, poet, and critic, and Sara Coleridge must have devoted herself to this pious labour. During her husband's life much of the collaboration and a considerable portion of the annotation fell to her share. After his death she did not hesitate to take upon herself the whole of the arduous labour. The 'Aids to Reflection,' 'Notes on Shakespeare' (withматеаты), and 'Dramatic Crichtons' (with 'The Times' were edited by her alone, and to some of them were affixed elaborate discourse on the most weighty matters in theology, morals, and philosophy, which were discussed in a cheerful and amiable manner. Her husband, a close observer of human nature, a kind of erudition quite remarkable in one of her sex. But Sara Coleridge, like her father, had in no stinted measure the imaginative as well as the reasoning faculty. Her fairy tale, 'Phantasmion' wanted only the colouring of verse to have employed him to rank among poets of the age; but in prose its often exquisite imagery and delicate shades of thought and feeling seemed to lack some clear and palpable intention; and it was regarded for the most part as vague, visionary, and obscure. Probably it was on her contemplations upon her father's work from which they are not likely to be by any future editor dissociated—that her fame will ultimately rest; but her rare acquirements and rarer gifts being thus expended on annotation, were not likely to be lost, on account of the very high order. Sara Coleridge survived her husband ten years. She died May 3rd, 1882. At her death she was engaged in preparing a new edition of her father's poems, which was completed and published by her brother, 'Poems of S. T. Coleridge. A Life of S. and S. Coleridge,' 1822.

COLESHEL. [WARWICKSHIRE]

Collins, William, R.A., was born in Great Titchfield-street, London, September 18, 1767. His father, a native of Wicklow, was the author of various works which attracted some notice in their day; among others a poem on the slave trade, a novel entitled 'Memoirs of a Picture,' and a 'Life of George Morland.' The elder Collins was a picture-dealer as well as an author, though in neither calling had he had much pecuniary success. Morland was a friend of his, and when his son began to exhibit a fondness for art and some skill in drawing, he readily obtained Morland's consent that the youth might stand beside him and watch him paint. William made tolerable progress in his pictorial studies. He entered in 1827 as a student at the Royal Academy at the same time as Etty, and in after life the two R.A.'s were fond of comparing their early drawings and subsequent progress. His earliest appearance as an exhibitor on the walls of the R.A. was in 1807, when he contributed two small 'Views on Millbank,' from that time till the age of two years when he was away in Italy, he did not miss an exhibition for the remaining nine-and-thirty years of his life. His father's death in 1813 threw upon the young painter serious responsibilities, which drove him on increased exertions. For some time he was forced to paint portraits as the readiest means of securing a moderate income, but his landscapes and rustic groups began to make their way, and he was soon enabled to follow the bent of his genius. Almost from the first he showed his fondness for painting groups of homely children engaged in some favourite diversion, or taking part in some country amusements; but it was not till five years later when he exhibited an election as associate of the Academy, which took place in 1814, that he struck into that path—the representation of coast scenery—which perhaps most surely led him to fame and fortune. From that time—indeed, for some or four years previous—Collins never waited for an opening, but placed his groups from first to last was of moderate but unbroken success.

As a painter of rustic life, or rather, perhaps, we ought to say of country children and homely country scenery, Collins had hardly a rival. He watched the habits and noted every movement, that was characteristic of country life, and failed to depict them in their most natural and unrestrained guise. Swinging on a gate, 'happy as a king;' gazing with unbounded admiration at the newly born pony;/editing the 'stay kitten;' outwitted by the sly rabbit just at the moment when his bow and arrow were about to fail on the bird's tail; exhibiting the fresh-found nest; buying the cherries—however the youngsters were represented the truth of the portraiture was at once apparent; and some quaint or novel incident was sure to be added, which marked more graphically than even the principal feature, the keenness of the painter's eye, and the skilfulness of his hand. In his coast scenes these characteristics were equally visible; and equally evident also was his happiness in his choice of subjects, and his attempt to surprise or excite. The painter knew exactly what was within the range of his powers. He saw his subject clearly; knew what he meant to accomplish, and seldom failed to accomplish it. Hence his pictures, apart altogether from the rich hue of his brush from the sky, sea, and land, were powerful representations of a land. They show that there was something which really interested and pleased the painter, and as a consequence the spectator is himself also interested and pleased. But their technical quality is of a very high order. Collins had an excellent eye for form, chiaroscuro, and colour. From the first he painted always with the greatest conscientiousness. He never slighted any part of his work, and always did his best; and hence his course exhibited continual progress. In his earlier works he was more bold, and the more bold arising from an excess of anxiety to render his work perfect. But, with increased command over his materials, he gradually acquired greater breadth and vigour; and though he always continued to finish his pictures with scrupulous care, he early recognised the truth of the axiom that no correctness of detail is not finish. And then with his technical and manipulative skill there was a close study of nature. The receding or advancing wave, the moist or parched sand, the whiteness of the clouds, the brightness of the sun, the redness of the sunbeam, the blue of the sea, and sky, were faithfully observed and unobtrusively represented. No wonder that a country like this, where every one can turn to the scenery of nature with never tiring zest, such faithful transcripts of a commoner aspect, until he had none like it. The blue of the sky, who, to city dwellers at least, always seem so genuine a part of the scenery, should have found abundant admirers and ready purchasers.

In 1830 Mr. Collins visited Italy, and remained there nearly two years; diligently availing himself of every opportunity of examining the works of the great masters, but at the same time filling his sketch-book with transcripts of the more striking features of nature and careful studies of the monks and peasants, and, above all, of the children, in that land of lazy enjoyment and perennial beauty. On his return in 1839, he sent to the academy at the fruits of his journey two views in Naples: one with groups of young lazaroni playing the game of 'arrogasie; the other with 'Poor Travellers at the door of a Cappelline Convent;' also a view at Subiaco. They manifested an increase of artistic knowledge and power, and were greatly admired. The next year he appeared in quite a new branch of that of historical painting. With increasing years, his brush became more stately, and the expression of his devotional feelings, and he not unusually felt a strong desire to represent in his own way the scenes on which his imagination loved to dwell. 'Our Saviour with the Doctors,' 'The Dying Child,' 'The Tempest,' 'The Two Disciples at Emmaus' in 1841. They of course attracted attention, and supplied a topic of conversacon in art circles, nor did they fail of purchasers; but it was felt to be a positive relief by the great body of the painter's admirers when, after a little coyling, a more open scenery in one or two small pictures exhibited in 1843, he
reappeared with all his old freshness and vigour in 1843 and succeeding years, with his "Windy Days," "Cromer Sands," and "Fawn Fishers," and "Cottage Doors," and the life; and never did Collins enjoy more general popularity as a painter than in these last three or four years of his life.

Collins's journey to Italy not only led him to waste on unconsumable subjects several of the best years of his life, but during it he laid the foundation of the disease which shortly afterwards led to his early death. New Moral Mansions, the book that at first he thought the heart declared itself in a decided form; but from that time he obtained only temporary relief from its distressing symptoms, though he laboured on at his calling with unaltered industry, and almost to the last with little perceptible loss of power. He died at his house, Devonport-street, Hyde Park Gardens, on the 2nd December 1847, at his house, Devonport-street, Hyde Park Gardens.

Collins was elected R.A. in 1820; in 1840 he was appointed librarian to the Academy, but resigned it on finding that its duties required a greater devotion of time than he could afford to give to it. Collins was, as we have already noticed, fortunate in early finding friendly and liberal patrons. As early as 1818 one of his Norfolk coast scenes obtained a place in the Royal Collection, and George IV. subsequently commissioned a companion to it—"Fawn Fishers at Hastings." Yet, though so much in request, the painter never obtained any of those extravagant sums for his works which we sometimes find popular painters demanding. The largest sum he ever received for a picture was 500 guineas, from Sir Robert Peel, for his picture of the "Pepper Pot," and the portraits of his countrymen are to be met with in most of the great private collections in this country. In the National Gallery the foreigner would look in vain for a specimen of this, one of the most characteristic and original painters of the school. The Vernon collection to a certain extent supplies the deficiency: there may be seen an excellent example of his delineations of rustic enjoyment in "Happy as a King," painted in 1836; one of his pleasant coast-scenes, in "The Shrimpers—Evening," painted in 1837; and his "Fisherman's Widow," painted in 1835. Mr. Collins married in 1822 the daughter of Mr. Geddes, A.R.A., and sister of Mrs. Carpenter, the well-known portrait-painter, and by her had two sons. COMBE, LAKESHIRE. COLOMBO, COLOMBINA, a genus of Plants belonging to the natural order Rhanaeaceae. It has a spreading 5-cleft calyx; petals 5, obovate-convolute; stigma 3. Fruit capsular, dehiscient, tricosous, girded at the base by the calyx. The seeds are furnished with a short stalk. The species are shrubs with alternate, entire, or crenulated leaves, netted with distasteful-nervous, smooth but usually pubescent or rusty villous. The flowers are in axillary short crowded cymes, or panicles. C. tormentosum, Fermented Snake-Wood, is a native of Guinea; the bitter bark of which tree is said to bring on violent fermentation in the liquors into which it is thrown.

There are several other species described, native of South America. In Argentina there are several which retain their name, but none are known, and are not worth cultivation except in general collections.

COLUMBITE. [COLUMBIUM.]

COLUMTRY. [DIOPSIDE.]

COLZA. [Brassica.]

COMBE, DR. ANDREW, was born in Edinburgh, October 27, 1797, the fifteenth child and seventh son of a family, which numbered seventeen in all. His father was a respectable tradesman, a man of superior mind and integrity; his mother also was a superior person. Educated in his boyhood and youth very much under the care of his elder brother George, the well-known phrenologist, he chose the medical profession; and, having studied at Edinburgh, graduated as B.Ch. in 1811, and as M.D. in 1813, he entered practice in Edinburgh in 1823. A pulmonary complaint under which he had laboured since 1811, and which obliged him to make frequent journeys into warmer climates, proved fatal to him. In 1815 he practised as a physician as he might otherwise have been fitted for. In 1836 he was appointed Consulting Physician to the King of the Belgians. As early as 1818 he had, like his brother George, given his attention to phrenology and become a convert to it; and before he had quitted his profession he continued to advocate its doctrines through the "Phrenological Journal." He was also a distinguished writer on general scientific and medical subjects. The following is a list of his most important separate works:—Observations on Mental Derangements," 12mo, Edinburgh 1831; 'The Principles of Physiology applied to the preservation of health, and to the improvement of physical and mental Education,' 8vo, Edinburgh, 1834—a work which has been highly appreciated, and has gone through sixteen separate editions; 'The Physiology of Digestion considered with relation to the Principles of Dietetics,' Edinburgh, 1836, also a most popular and useful work; 'A Treatise on the Physiological and Medical Aspects of Mental Fatigue,' Edinburgh, 1840, eight editions of which have been sold. These works were written by Dr. Combe in the intervals during which he enjoyed comparative freedom from the malady which he knew was to carry him away. The last years of his life were spent by him as a recluse, either shut up in his room in Edinburgh, or seeking health by continued travelling and sea-voyages. In 1843 he was in Madeira. The mildness of his demeanour during his long illness, and the seal with which he continued to forward his scheme of benevolence which accorded with his sense of what was right and expedient, obtained him the peculiar regard of all who knew him. His death, long expected, took place on the 9th of August 1847. An interesting and affectionate account of his 'Life and Correspondence' was published in 1850 by his brother George.

COMBE MARTIN. [DIOPSIDE.]

COMPOUND RADICLE. [CHEMISTRY, S. 8.]

COMTE, AUGUSTE, a French philosopher, whose peculiar system of views has been put forth by himself, and is generally known by the name of "Positive Philosophy," was born within a year or two of the close of the last century. His family was strongly Catholic and royalist. Educated at one of the French lyceums, he gave early evidence of the kind of mind, but also of a dissatisfaction with the existing methods of knowledge and the existing forms of society, and a belief that he was destined to play the part of a Bacon in the 19th century, and initiate a new philosophical revolution. It is characteristic of the Comte and the Fenian movement between the fifth and sixtieth year, drew around him, as by a kind of magnetic fascination, a number of ardent young men, whom he indoctrinated with his views, and almost all of whom— notwithstanding that few of them in mature years have adhered to his system of views some degree of originality and distinction in one way or another in the subsequent history of France. Of these Comte was the youngest—the Benjamin, as he was called, of the Saint-Simonian school. In 1830 the Saint-Simonian order was suppressed; and when, about 1830, the school put forth one of their prophetic proclamations, an exposition of the scientific basis of their system, it was on Comte that the preparation of the work devolved. The work entitled "Système de Politique Positive" however only partially satisfied Saint-Simon, who said that while "it has expanded the generalities of his system from the Aristotelian point of view," it overlooked "their religious and sentimental aspect." The truth is, Saint-Simon and Comte were beginning to part company. The discrepancy did not become destructive of the doctrine itself until when Comte broke off from the little band of Saint-Simonians—including Enfantin, Bazard, Rodrigues, and Augustin Thierry—who remained faithful to the views of their master, and set about forming an organisation for their further propagation. Comte subsequently spoke disparagingly of Saint-Simon, and represented his temporary connection with that enthusiast as rather an interruption to his own true intellectual development than a furtherance of it; but in the course of the subsequent works and the cardinal speculations promulgated by Saint-Simon when alive, that, unless we can suppose that the pupil prompted the master to a greater extent than usual, is more than likely to have been the cause of M. Comte's a certain appearance of ingratitude in his allusions to this part of his education. In 1826 M. Comte was seized with what he calls 'a cerebral crisis,' which for the time was believed to be irrecoverable insanity. He did recover however, and lived to propound the philosophy with U?"
which his name is associated. Supporting himself by teaching mathematics—in which capacity he was professor at the École Polytechnique, till differences with his colleagues and the accession of Louis Napoleon to the empire deprived him of his office, and reduced him to a state of indigence in which his chief support consisted of voluntary contributions from some of his pupils—and during the last seven and twenty years a series of works, all devoted to the elucidation of his 'Positive Philosophy,' and in which those who have no sympathy with that system in its principles and extent, or who are able to recognize great power of intellect, and extraordinary fertility of generalisation on all subjects,

First, published at intervals in six large volumes, between 1830 and 1849, came out his greatest work, entitled 'Cours de Philosophie Positive.' In this work he established his main doctrine, which is, that the human mind has, by a natural law, passed through three successive stages in its thoughts upon all subjects; namely, the theological stage, in which phenomena are accounted for by the suggestion of the agency of supernatural beings to produce them; the metaphysical stage, in which, while living supernatural beings are got rid of, certain abstract ideas, such as those involved in the words 'Nature,' 'Harmony,' and the like, take the place; and finally the positive stage, in which everything is accounted for; and the positive stage, in which, shaking off both unseen spiritual agencies and abstractions, the mind grasps the notion of the universe in all its departments as proceeding according to certain laws or uniform sequences, to which the human mind is provided with faculties sufficient to this end, and with an inclination to apply this view to the entire system of human knowledge.

That all men knows, or can know, he says, consists of certain sciences which may be arranged in a hierarchical order as follows, according to the increasing complexity and of the facts with which they respectively deal.

1st, Mathematics, the most general and simple of all, which deals with the mere facts of number and magnitude; 2nd, Astronomy, which presupposes mathematics, but takes in addition the motions of the celestial bodies, such as the planets, moons, comets, &c., as they are seen as mutually acting masses; 3rd, General Physics, which takes for granted mathematical and astronomical laws, but concerns itself also with the motions and other mechanical phenomena of bodies on our earth; 4th, Chemistry, which, in like manner, presupposes all the foregoing, but investigates farther the phenomena of the molecular changes and constitution of bodies; 5th, Biology (subdivided into Vegetable and Animal), and involving Psychology as a department of Animal Biology concerned more immediately with the phenomena of nervous and brain-function), undertaking the farther study of individual organised beings; and 6th, Sociology or the Social Science, investigating, as the most complex phenomena of all, the social organization of man, i.e. the State and its laws. Of these first five sciences Comte gives prominence to the last.

In 1843 only, the first four of these sciences have been even partially emancipated from the theological and metaphysical stage, but pursued positively; but the time had come when the extension of the true positive or scientific spirit has come to all, and consequently for the expulsion of theology and metaphysics from the universe. As the apostle of this great speculative change he first reviewed the various sciences up to the last and chief one, which, by a gross but convenient generalisation, he called Sociology, giving in fact a series of treatises in which the generalities of mathematics, astronomy, general physics, chemistry, and biology, are lucidly expounded, and then proceeds to stress his strength, in the last three volumes, for Sociology. Here he makes his plea for a complete conquest of the realm of the human and against the anarchy of all existing politics, attempts to lay down the basis of a true or positive politics, such as states will ultimately be governed by, when the positive millennium shall have come. Apart from the main purpose, this portion of the work abounds with striking thoughts and propositions of wide application.

In 1848 M. Comte published a small mathematical work entitled 'Traité Elémentaire de Géométrie Analytique à deux ou trois dimensions,' followed a long afterwards by a popular treatise on astronomy, which has been highly admired; and in 1844 he published 'Discours sur l'Esprit Positif,' enforcing popularly the ideas of his larger work. With this, however, he made the fatal 'cerebral crisis' of his life—not this time of the 'cerebral kid' but of the sentimental—worked a change in his views. A virtuous affection, to which he makes frequent allusion in subsequent autobiographic passages in his philosophy, for a lady named Clotilde, whose death left him miserable, revealed to him, what Saint-Simon had long before hinted, the deficiency and meagreness of his philosophy on the sentimental and religious side. To make up this deficiency was the object of all his later activity. This he attempted to do, not by modifying the main principles of his system, but not by calling back either cashiered theology or cashiered metaphysics into the universe, but by supplementing positivism with the necessary effusion from the heart. In fact, during the last four years of his life he worked on a new system, a kind of a new religion, consistent with the fundamental doctrine of positivism; to accomplish which, seeing that positivism denies deity or invisible spirits of any kind apart from humanity, he makes humanity itself the object of the new worship. In 1848 he published 'Traité d'Ethique Positiviste' and 'Traité de la Philosophie Positive,' in which the notion of the new religion, as the necessary appendix to his philosophy, was promulgated, and in 1849 he published a singular book of a more precise nature, entitled 'Culte Systematique de l'Humanité: Cale- drier Positiviste, ou Système General de Commemoration publique,' in which work he proposed a systematic worship by humanity of itself, as represented in its greatest men of all ages—twelve of whom he specified as worthy to preside over the religion, and to whom he denominated subordinate men, and for each day minor celebrations it (it was singular to the reader to note how many Frenchmen there were among these gods and goddesses) and also arranged some of the formalities of the worship. In these works he also published the programme of an Exposition de la Religion Universelle en onzo Entretiens Systematiques entre une Femme et un Prêtre de l'Humanité.' M. Comte himself giving in the meantime practical effect to his views by assuming the office and title of 'Chief of the Societies of the new religion.' The character of this work is not open to question, but it is not generally admitted that he could ordain his successor in the chair of the new philosophy and the pontificate of the new religion. M. Comte died Sept. 5, 1857.

Those who desire further information respecting the life and views of this very extraordinary personage, will find it either in his own works above enumerated, or in two works published in this country presenting an abstract of his views—Comte's Philosophy of the Sciences, being an Exposition of the Social Science, translated by Miss Harriet Martineau's 'Positive Philosophy of Auguste Comte freely translated and condensed' (5 vols. 1853.) Comte's 'Philosophy of Mathematics,' translated from his main work, has been translated in America by W. M. Gillespie; and his 'Popular Astronomy' also, if we mistake not, has found an English translator.

CONDAMNEA, a genus of Plants belonging to the natural order Convolvulaceae. It has a campanulate calyx, stamens and pistil united, and the corolla funnelform, with a somewhat curved tube, which is a little longer than the calyx, a dilated throat, and 6-parted limb; the filaments inserted above the middle of the tube and near the throat; anthers oblong, linear, bifid at the base, length of corolla 2-3 times the limb, opening in the middle of the cells. Seeds numerous, very small, wedge-shaped. The species are American shrubs, with 2-parted acuminate stipites and terminal many-flowered cymes.

C. corombose is a native of the hills and ravines of the Peruvian Andes. It has ovate-oblong leaves, acuminate, cordate, sessile, plicated, coriaceous; coryzae large, bractiaceous, trichome; corolla purple externally, with the throat crimson; seeds numerous, very small, smooth. The bark is fibrous. The bark gatherers of Peru are said to use this plant for adulterating samples of Convolvulus. Its bark is only slightly bitter, and may be easily recognised by its being white inside, rather bitter, and viscid. C. corombose is a native of South America, and is used occasionally as a dye.

CONĐER, JOSIAH, was born in London on the 17th of
September, 1789. He was the son of a bookseller, and very early displayed a taste for literature. His first attempts were given to the world in the 'Athensium,' a monthly magazine edited by Dr. Alkin; and in 1810, in conjunction with a few friends, a volume of poems was published under the title of 'The Associate Minstrel.' In 1814, being at the time a publisher and bookseller in St. Paul's Churchyard, he purchased the 'Eclectic Review,' of which he continued to be editor and proprietor, and in 1818 he left business in London for the bookselling business in 1819. Under his management the 'Eclectic Review' received the assistance of many eminent men among the non-conformists, such as Robert Hall, John Foster, Dr. Chalmers, Dr. Vaughan, and others. During this period, his industry was dispensed by the products of his press, which were many. He also in 1818 appeared two volumes 'On Protestant Non-Conformity.' In 1814 'The Modern Traveller' was commenced: it extended to thirty-three volumes, nearly the whole of which were compiled by Mr. Corry and all under his superintendence. In 1824 also appeared 'The Star in the East,' a poem; and in 1834 a 'Dictionary of Geography,' and a new translation of the 'Epistle to the Hebrews, with Notes.' In 1836 he edited 'The Congregational Hymn-Book,' issued under the sanction of the Congregational Union; and in 1837 he published 'The Choir and Oratory: Sacred Poems,' to which Mrs. Conder was a contributor. He was the author of many other works, but we have mentioned the greatest only.

Mr. Conder's reputation having become established among the Dissenters, he was requested in 1832 to undertake the editorship of 'The Patriot,' a newspaper recently established in the dissenting interest. From this time he took a more active part in public affairs. He took an active part in the public proceedings of the Dissenters, attending their meetings, and affording them the assistance of his counsel. 'The Patriot,' under Mr. Conder's management, became the organ of what may be termed in politics the Wing section of the Dissenters, as opposed to the Radical section; while in ecclesiastical affairs it represented the Congregationalists and Baptists. For twenty-three years Mr. Conder fulfilled the duties of his office with exemplary care, industry, and liberality; producing also occasionally works of influence, such as 'Discussions on Analytical and Comparative Views of All Religion,' 'The History of Hymns with Pictures,' &c., and several pamphlets on stirring topics of the day.

Mr. Conder married in 1815 Jane Elizabeth, the daughter of Mr. Thomas of Southgate, by whom he left four sons and a daughter. After a short illness, he died on Dec. 27, 1855.

CONFEDERATION, ARGENTINE. [Plata, Lo., States of]

CONIA. [Chemistry, S. 1.]

CONIONA. [Chemistry, S. 1.]

CONOPS. [Chemistry, S. 1.]

All the Courts of Science, Courts of Requests, and other similar tribunals were abolished in 1846, by the statute 9 & 10 Vict. c. 95, on the creation of the new County Courts. [Courts, S. 2.]

CONOPS, a genus of Insects belonging to the order Diptera, family Conopidae. The family Conopidae is thus characterized:—Protoposis distinct, last joints of antennae forming a short style. Wings perfect. Cubital vein simple; brachial veins without spurious vein; axillary lobe rounded. Halteres uncovered.

The genus Conops has the following characters:—Body of middle size, rather slender, generally adorned with yellow or red bands. Head thick, vestigial, the crown especially, with a transverse vestigial tubercle; front broad in both sexes, and with a transverse vestigial tubercle. Mouth long, porrect, stilt, clavate, horizontal, or somewhat raised into a curve, geniculate at the base, arcade above, hollow beneath, obliquely notched at the tip, much shorter than the labium. Labium slender, filiform, transparent. Palpi unarticulate, short, very small, fringed at the tips with fine bristles. Labium obliquely procere, cylindrical, twice the length of the hind, narrower towards the tip, most slender in the male, blibed, slightly hairy, and with three shallow transverse impressions. Hind tibia, with a subapical head, porrect, seated on a tubercle, approximate at the base, diverging thence; first joint short, cylindrical, pubescent, forming an angle with the second; second long, sub-clavate; third conical, shorter than the second; fourth very short; fifth and sixth each on one side. Thorax short and thick, rather stout, tibias very slightly curved, compressed and dilated at the tights, in some cases with a transverse suture; tarsi rather broad; ungues and onychia distinct.

Male.—A peculiar form in a projecting conical process on the fourth segment beneath. These flies frequent flowers; their larvae are parasitic on those of the humble-bee. There are twenty species of this insect in the collection at the British Museum, of these not more than three or four are found in England; the others having been caught in the south of France, North America, and Australia.

A single specimen of C. strigata was found near Killarney, in Ireland, in the summer of 1856. (Walker, 'Insecta Britannicae.')

CONSTANTINA. [Constanitsa.]

CONYBEARE, VERY REV. WILLIAM DANIEL, Dean of Llandaff, was born at his father's rectory, St. Botolph's, Bishopsgate, London, June 7, 1757. He entered Christchurch College, Oxford, in January 1779, and took his degrees B.A. in 1808, and M.A. in 1811. Mr. Conybeare was one of the earliest promoters of the Geological Society, and the important services he rendered to geological science may be seen in his numerous papers printed in the Society's Transactions. He is an acute observer of the objects of the physical geography of important districts, and establishing the relations of some of the most remarkable British rocks, and their order of superposition, have furnished data for practical purposes, and show how the absurd misinterpretations of the speculations of the early writers are to be accounted for. His works and articles are little seen from the subjoined titles, his researches were extended to various branches of inquiry. His first paper presented to the Geological Society was 'On the Origin of a remarkable mass of Organised Impressions occurring in Nodules of Flint,' vol. ii., 1814; 'Descriptive Notes referring to the Outline of Sections presented by a Part of the Coasts of Antrim and Derry,' vol. iii., 1816, made a tour conjointly with the Rev. Dr. Buckland, Dean of Westminster; ' Notice of the Discovery of a New Fossil Animal, forming a link between the Ichthyosaurus and Crocodile,' &c., vol. v., 1821. In vol. i., new series, 1854, further notices are given, and ' On the Discovery of an almost perfect Skeleton of the Plesiosaurus; and the same volume contains Observations on the South-Western Coal Districts.' He was a member of the jury of the Royal Society, and of the Royal Society of Antiquaries; 'Extraordinary Landlap and great Convulsion of the Coast near Aixmouth,' Jameson's 'Edin. Journal,' 1840; ' On the Phenomena of Geology which seem to bear most directly on the Laws of the Primordial Mag.' vol. viii., and ix., second series; 'On the Structure and extent of the South-Welsh Coal Basin,' 8th vol. xi.; 'Outlines of the Geology of England and Wales,' with an introductory Compendium of the General Principles of that Science,' &c., 8vo, London, 1829 (conjointly with W. Phillips). He also drew up the 'Report on the Progress, Actual State, and Ulterior Prospects of Geological Science,' published in the first volume of the 'Reports of the British Association.' Mr. Conybeare was elected a fellow of the Royal Society in 1818. He became a Fellow of the Geographical Society, and a corresponding member of the Institute of France. He became Dean of Llandaff in 1845, having previously been public preacher in his own university, and Bampton lecturer in 1830. He died after three hours' illness, on August 13th, 1877, at Ilchen Stoke vicarage, while staying with his third son.

COOKIA, a genus of plants belonging to the natural order Astareaeae. The species are small trees with imparipinnate leaves; leaflets alternate, unequal at the base, or oblique. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base. C. Cookii has a stem as high as 30 feet, with lanceolate leaves, acuminate, hardly unequal at the base.

COOKINON, a medium-sized tree bearing edible fruit about the size of a pigeon's egg, yellow on the outside, the pulp white, rather dense, somewhat flinty, and the fruit is esteemed popular articles of diet in China and the Indian Archipelago, and is known by the name of Wampee. There are two or three other species, natives of the East, all known as Wampee Trees.

COOKSTOWN. [Tyrone.]

COOPER, JAMES FENNIMORE, was born at Burlington,
New Jersey, United States, on the 16th of September, 1789. His father was a Buckinghamshire family, which emigrated to America at the age of nineteen years for the purpose of becoming future novelists. When James was about two years old his father removed to the banks of the picturesque Otsego Lake, Western New York, and there founded the village of Cooperstown.; and somewhat later he was elected a judge of the county court. He also wrote on the same subject in the rudimentary branches of learning, he transferred him to the care of the Rev. J. Ellison, an Episcopal clergyman at Albany, by whom he was prepared for college. He remained at this place until 1803, when, having taken his degree, he entered the navy as a midshipman. He served at sea for six years, and his conduct won the approbation of his superiors, and the esteem of his fellow-officers. It was here he acquired that familiarity with a maritime life, and knowledge of the sea and the phenomena of nautical life, that lend such a charm to his naval stories. On retiring from the service he in 1811 married Miss Delancy, a sister of Bishop Delancy of New York, and took up his abode in the neighboring village of Cooperstown.

His next few years were spent in private life. It was not until 1821 that Mr. Cooper appeared as an author. His first work was a novel, "Precaution," which professed to be a story of English life. It met with no success, but the author, liking the venture, undertook another public notice with "The Spy—a tale of the Neutral Ground." A thoroughly original and genuine American novel caught the American ear, much as "Waverley" had caught the Scottish. Its success was immediate and unbounded. In England its vivid pictures of the characters and scenery of the frontier, its additional charm of novelty, and Cooper at once took rank with the leading novelists of the day. The "Pioneers" followed in 1823, and confirmed the reputation of its author. A year later appeared "The Prairie," and in 1826 "The Tam-o'-Shanter." These were the types of a long series of novels which during many years flowed from Cooper's prolific pen. He had in them brought before his readers the mighty forests and wide prairies,—the backwoods of America, with their original occupants, the red men; the English settlement, and the English and black settlers, who were rapidly supplanting them; and the sea with its daring American privateers; and again and again he was to reproduce these in more or less varied forms. The strength of his narrative, his power in delineating character, his command of the passions, keenness of observation, and descriptive skill were acknowledged without stint, and America was admitted to have produced a great original novelist.

Like Scott, thought the tide of success was to be taken at the full; and he published novel after novel with a rapidity rivalling that of the author of "Waverley." For a time his imagination and stores of knowledge appeared to sustain without diminution the heavy drain. He was never hindered by the multiplicity of characters which the reader along with more rapidity and interest, than in the "Prairie" and the "Last of the Mohicans," which appeared after "Lionel Lincon" and one or two others, in 1830; in the "Red Rover" and the "Waver Witch, and the "West of the Wish-Ton-Wish," which followed in succeeding years. But in these and a few others he exhausted his genius, and novels like "Ned Myers," "The Sea Lions," "Mercedes of Castille," and "The Headman of Berne," served only to call into clearer notice the weak points of his author; yet the "Deerlayer" and one or two of his later stories had so much of beauty and strength, that had there been no intervening failures, there would have been little reason to fancy that the hand of the great American novelist had lost its skill.

In 1829 Mr. Cooper visited Europe, where he remained for about ten years, his longest sojourns being made in London and Paris. The fruits of his European travel were the novels of "The Heart's Desire," "The Bravo," "Heidrun," and "Mercedes," none of which were very successful; "Homeward Bound," and "Home as Found," which, with the Introductory Letter to his Countrymen," stirred up some strong feeling. Nor was he, as we have already intimated, altogether happy in the literary world, and his machinations in America, although in several of them he recurred to his old American forests and sea haunts. But he wandered also often into the regions of home and foreign politics, not even keeping clear of the hustings; and his very iniquity for reasoning rendered him the more dogmatic in maintaining his own views and inexcusable under contradiction or dissent.

Some of his home critics he prosecuted for libel; his foreign opponents he denounced with unbounded wrath. However, in 1831, he returned to America, and was rewarded at home and abroad with a return of the old admiration and esteem; so that his death, which occurred at Cooperstown on the 14th of September, 1851, caused a general expression of sorrow. He was one of the most esteemed in this country, where he had hardly fewer readers and admirers than in his own land.

Besides the novels mentioned above, Mr. Cooper wrote "The Pathfinder," "The Monikins," "The Two Admirals," "The Spy and the Shepherd," "The Virginian," "The Autobiography of a Pocket Handkerchief," "Satanas, the Chainbearer," "The Crater," "Oak Openings," "Jack Yer," "The Sea Lions," and we believe one or two others. He also wrote a History of the United States Navy, which does not give an adequate idea of his abilities. He had also written for the American Naval Officers, "Gleanings in Europe," "Sketches of Switzerland," "Notions of the Americans by a Travelling Bachelor," and "The Way of the West." Most European languages have translations of some of Cooper's novels, and it is stated that one or two of the Oriental tongues possess a version of at least one of his stories. Most of the earlier novels and several of the later have been rendered into German; and in French there is a translation by Delacroix of "The Spy" and of another in 6 vols. by Messrs. Laroche and de Montémond.

Coot hill, county of Cavan, Ireland, a post-town and the seat of a Poor-Law Union, in the parish of Drumreagh, and in the barony of Ignatia, county of Monaghan, 54° 57' N. lat. 7° 2' W. long. 73 miles N.N.W. from Dublin. The population in 1851 was 3105, besides 1101 in the Union workhouse and other public institutions. Coothill Poor-Law Union has 19 electoral divisions, with an area of 106,648 acres, and a population in 1851 of 44,333.

Coothill lies on the road from Kingscourt to Clones, and has four principal streets, which are wide and substantially built. It contains a neat church, besides chapels for Roman Catholics and Church of Ireland. There is here a bank of agriculture.

There is here a brick trade in linens, and a large market for agricultural produce. The town stands at the western extremity of a series of lakes which are navigable for the greater part of the distance (7 miles) hence to Ballybay. The neighbourhood is well cultivated, and returned with numerous demesnes and mansions. Quarter sessions for the county are held at Coothill. There are here a bridge, a dispensary, and a station of the constabulary force. A fair is held on the 1st of July in each year.

Copleston, Rev. Edward, D.D., was born Febry 2, 1776, at the rectory-house, Offwell, Devonshire. His father, the Rev. John Bradford Copleston, was the rector of that parish, and he educated at his own residence a limited number of young men. In 1791 Edward Copleston was elected to a scholarship at Corpus Christi, Oxford; and in 1793 he obtained the Chancellor's prize for a Latin poem; and in 1796 he was elected a Fellow of Oriel College, and obtained the Chancellor's "English essay on Agriculture," in 1796, and in 1797 was appointed college-tutor, though he had not then taken his degree of M.A. In 1802 he was elected Professor of Poetry to the university, in which office he succeeded Dr. Harris. He published in 1812 the substance of the lectures which he had delivered, under the title of "Prelections Academicae," a work which gained him a high reputation for pure and elegant Latin composition combined with extensive poetical information. Some severe attacks on the University of Oxford having been made in the Edinburgh Review, Mr. Copleston published in 1810 'A Reply to the Calumnies of the Edinburgh Review against Oxford,' which was followed by another "Reply." This was in the same year, and by a third in 1811. These replies were greatly esteemed, and were generally regarded as a triumphant defence. In 1814 Copleston was elected Provost of Oriel College, and soon afterwards the degree of D.D. was conferred upon him by the diploma, the instrument setting forth that this distinction resulted from the "gratia nobis," which he had conferred upon the university. Dr. Copleston is chiefly remembered as a divine by his work on "Predestination," which consists, for the most part, of three sermons preached at St. John's church, Oxford, An Enquiry into the Condition of Absentees, with Notes and an Appendix on the 17th Article of the Church of England;
of London, 1821. Between the years 1811 and 1818 he contributed many articles to the Quarterly Review.

In 1819 Dr. Copleston was appointed to the deanery of Chester, and in 1827 he succeeded Dr. Summer in the bishopric of Landaff and deanery of St. Paul's, London. He also held the honorary appointment of professor of ancient history to the Royal Academy of Arts, and was an influential member of Antiquaries. After he became a bishop his time was chiefly occupied in the performance of the duties of his diocese. Some of his sermons, charges, and speeches in the House of Lords, were published at the time they were delivered. He resided in a spacious mansion in the vicinity of his life at Hardwick House, near Chesham, where he died October 14, 1849. (Memoirs of E. Copleston, Bishop of Landaff, with Selections from his Diary and Correspondence, &c., by William James). Copleston.

COPROLITES (odorif., and solid), the fossilised excrements of reptiles, fish, and other animals, found in various strata of the earth. Dr. Buckland in his Bridgewater Treatises first drew attention to the probable nature of these objects, some of which had been formerly only known under the name of Benzo Stones. These fossils were first detected in the Lias at Lyme Regis and in other localities, and their true nature inferred from the fact of their identity with similar masses found actually within the body of many species of land and sea reptiles. The excrement contains scales of fish, and occasionally teeth, and fragments of bone, belonging to species of fishes and reptiles which have been swallowed by the animal as food, and have passed through its stomach in the form of a spirally twisted form, which is a characteristic of the excrement of the larger forms of recent fish, and has been accepted by comparative anatomists as indications of the nature of the intestinal tube in the extinct forms of reptiles.

Professor Liefig says in his Letters on Chemistry, "In the autumn of 1842 Dr. Buckland pointed out to me a bed of Coprolites in the neighbourhood of Clifton, from half to one foot thick, inclosed in a limestone formation, extending for a distance of two miles. The animal which excreted the coprolite was identified by me as a species of the genus Cricetus of the Severn. The limestone marl of Lyme Regis consists for the most part of one fourth part of fossil excrements and bones. The same are abundant in the Lias of Batheston, and Broadway Hill, near Evesham. Dr. Buckland mentions the bone of the testa of Brachyurus, and a fragment of the outer coat of Ginkgo, which are preserved in various strata of the earth. The latter is a bed of Coprolite afforded deposits of phosphatic lime which have received the name of Coprolite, but they have also been found in the Greensand, in the Wealden Formation, and in the Red Crag. In the latter formation it may be altogether doubted as to whether the phosphatic lime there found in the form of dark-brown or blackish smooth nodules, can be appropriately called Coprolites. These nodules occur in beds or seams running through the Red Crag of Suffolk, where, in the neighbourhood of Ipswich and Woodbridge, and on the sea-coast of Felixstow and Bawsey, it is worked to a considerable extent. In England, as in France, the bones of various forms of Cricetus, all of which contain large quantities of phosphatic lime, and are collected under the name of Coprolites. It is still a question of interest as to how the nodules not having an organic basis have been formed. The surface of the earth is lined with numerous nodules of lime are derived from the destruction of organized beings, but it is very evident that phosphatic lime must have existed in some form or another before the creation of either vegetable or animal life. The supposed phosphatic lime is composed of individuals of species of plants and animals demand that there should be some constant supply of this substance from the mineral kingdom. Whatever may be the result of further inquiry on this point, there can be little doubt of the improbability of calling all deposits of phosphatic lime Coprolites. A better general name and which is not exposed to the objection of a false theory would be Phosphatite."

COPYHOLD. The statute 4 & 5 Vict. c. 35, has been amended by the 6 & 7 Vict. c. 23; 7 & 8 Vict. c. 55; and 15 & 16 Vict. c. 51. The result of these statutes may be shortly stated thus. The lord may now be compelled by the tenant, after the term expires, to enrich the copyhold at the first surrender and admittance that takes place, and on terms, if the parties cannot agree, to be fixed by the Copyhold Commissioners.

COPYRIGHT. In order to take advantage of any disposition which may be manifested by foreign nations to recognize British copyrights, powers have been conferred on the Sovereign, by the stat. 7 & 8 Vict. c. 19, to grant, by Order in Council, privileges of copyright in this country to the authors of books or compositions, which shall be published outside the country. The exclusive right of representation may in like manner be granted to the authors of dramatic or musical compositions. Such Order in Council cannot, however, be made until due protection for British copyrights has been secured by the government of the country in the subjects of which the privilege of copyright in this country is conceded.

Under this Act, conventions for the mutual protection of copyrights have been entered into with the following countries: the United States, 1842 and 1846; Canada, 1846; Russia, 1848; Greece, 1849; France, 1850; the Netherlands, 1851; Belgium, 1853; Germany, 1855; Sweden, 1856; Switzerland, 1857; and Denmark, 1857. I. As to the ratifications have been made by the United States, 1846 and 1849, and by the United States, 1846 and 1849. 16 & 16 Vict. c. 19. Authorised translations of foreign books and dramatic pieces are by this statute protected for a term not exceeding five years from publication.

The Design Act, 1840, enables designs to be provisionally registered for one year, and confers powers on the Board of Trade to extend the copyright for a term of three years. The same statute provides for the registration and protection against piracy of sculpture, models, copies, and casts. The works of art, as well as books, are protected by the statute 16 & 16 Vict. c. 19, to prints taken by lithography, or other process of indefinite multiplication. ("Blackstone's Commentaries," Mr. Kerry's ed., vol. ii. pp. 416-417).

4. Hidrulbrandeisii. - The feld cartilagineo-membranaceous (not stony), crustaceous, suborbicular, adhering by its lower surface; composed of very slender closely-packed web-like filaments imbedded in the feld, orbicular, depressed, pierced by a hole, and containing tetraspores and paraphyses at the base of the cavity.

H. rubra is found on smooth stones and pebbles between tide-marks and in deep water. It is very common, and forms a thin, moist, infectious film on the surface of a smooth stone covered with water. When the water in the V-shaped troughs is filled with diatoms, it is attached to a chal-acteristic body by which it may be attached. Viewed under the microscope, a small portion shows minute cells lying in a close-packed mass, which is covered with diatoms, the scale-like depressions, pierced by a hole which communicates with a chamber in which the spores lie. The colour is variable; now a bright, now a dull red.

Sub-order 3. (I) Loliaceae. Loliaceae. - Plant calcareous, consisting of a single plane of cells, which are disposed in radiating dichotomous series, forming an uppressed flabelliform frond. Named from a stone in the bladder, because the cells have stony costs.

5. A. Allmannii is parasitical on Chrysogena clavalessii from an oyster-bed at Malahide, Dublin, by Professor Allmann. It forms minute dot-like patches of a whitish colour on the surface of the shell. It grows in chains of two or three, or several fan-shaped fronds composed of quadrate cells disposed in dichotomous series. The plant is brittle, colourless, and effuse in acid water.

(Harvey, Britton Myce.)

C. deinaperta (Buchneri.-L.)

C. CORBULA, a genus of Marine Mollusca, belonging to the Littoriliombranata. The shell is suborbicular or oval, tumid or depressed, very inequivalve, slightly inequilateral, rounded anteriorly, more or less truncated posteriorly; the prominent surface of the valves more or less furrowed or transversely striated, covered with an epidermis. Hinge composed of a recurved primary tooth in one or both valves, with corresponding socket and ligamental pit beside it. Ligament small, calcareous, tubular impressions slightly marked, united by a pulvinate one with a very slight sinus. The animal is short, with very short united siphonal tubes. Unicissum frambes. Mouth closed, except in front, where there is an opening for a bayon narrow thick foot of considerable dimensions. Anal siphon with a conspicuous tubular membrane. Labial tentacles slender.

This genus was once abundant in the European seas, especially during the early part of the Tertiary epoch. Only a few species are now existing. It has more species in the tropical seas of the present day.

C. nucleus is one of the most common species in the seas around the British Islands. Whilst very frequently found in the dredges, it is seldom washed on shore or found in shallow water. It attains half an inch in length and about one-fourth less in breadth.

This genus belongs to De Blainville's family Fyllidae, which embraces Solen, Panopone, Mya, and other allied species. [Pyelospira.]

CORBY. [Lincolnshire.]

CORCHORUS, a genus of Plants belonging to the natural order Tiliaeae. The leaves of C. olitorius are used in Egypt as a pot herb. Fishing-lines and nets, rice bags, and a coarse kind of linen called tat, are made in India of the fibres of C. espurrius.

CORDIA, a genus of Plants belonging to the natural order Cordisaeae. It has a tubular calyx, 4-5 toothed. Corolla funnel-shaped or campanulate, with a flat-6-cleft limb, and a hairy or naked throat. Stamens 5 short, inserted in the throat of the corolla. Style protuding, bifid, with 4 stigmas. Ovary 3-4 celled. Drupe containing 1 stone with 1 or 3 cells, two of which are usually abortive.

C. citrifolia is a native of Hindustan. It has numerous spreading and drooping branches; the young shoots angular and smooth. The general height of trees ten or twelve years old about 20 feet. Leaves alternate, petiolate, round, cordate, and oval, often slightly repand; surface is hispid, dark, tawny and pale underneath; from 3 to 7 or even 8 inches long, and rather less in breadth. Petioles nearly rounded and smooth. Panicles short, terminal, and lateral, roundish; the branches alternate, diverging, and one or more frequently dichotomous. Flowers numerous, small, white. Bracts minute, villous. Calyx villous, campanulate, leathery; mouth unequally toothed. Corolla short, campylate. Segments 5, linear oblong; filaments as long as the segments of the corolla, and inserted immediately under their bases. Style short. Stigma 4-cleft; segments long, rugose, and recurved. Drupe oblate-spheroidal, about an inch in diameter and a quarter in diameter; smooth when ripe, straw-coloured, and rather thick; the edible part is the entire fruit. The native species are: C. Plums, Sebastans, or Sepistans, two sorts of Indian fruit, have been employed as pectoral medicines, for which their mucilaginous qualities, combined with some astrigency, have recommended them. The fruit are said to be good for the "Pensa" of Dioscorides. Linnaeus has erroneously applied the name of Sebasten to an American species of this genus which is not known in medicine.

C. hystrix is a native of many parts of India, Persia, Arabia, and Egypt. The fruit is generally crooked, from 8 to 18 feet high, and as thick or thicker than a man's body. The dark gray, cracked in various directions. Branches numerous, spreading, and bent in every possible direction, forming a dense shaggy head. The flowers are numerous, white, small; from very large proportion of them are sterile, and they always want the style. The drupe is globular, smooth, the size of a cherry, sitting in the enlarged calyx; when ripe, yellow; the pulp is almost transparent, very tough, and viscid. The fruit is used as a condiment, and in the tinctures of the taste of the kernels like that of filberts. It is the true Sebasten of the European Materia Medica. The fruits, according to Roxburgh, are not used in the Circassian medicinally, but when ripe are eaten by the natives, and also most greedily by the grazing of a sweetish taste. The wood is soft, and of little use except for fuel. It is reckoned one of the best kinds for kindling fire by friction, and is thought to have furnished the wood from which the Egyptians constructed their mummy cases. The wood is said by Dr. Boyle to be accounted a mild poison.

C. erumcrocarcinus is a native of the West Indies in woods, and of Mexico, near Acapulco. It has ovoite oblong leaves, acute, quite entire, glabrous; racemose terminal, aggregate; calyx sepals very large; calyx 10-cleft; corolla 5-cleft; stamens 10; ovary downy; limb of corolla 5-cleft; staminate; stamens the length of the corolla. This is esteemed one of the best timber-trees in Jamaica, of which it is a native. The wood is of a dark brown colour, and gently striated; it is tough and elastic, of a fine grain, and easily worked. It is called Spanish Elm or Prince Wood by the English, and Bois de Chypré by the French.

C. rumphii has brown wood beautifully veined with black, andsmall black dots.

There are above 100 species of this genus.

CORDOVA, the most important next to Buenos Ayres of the provinces of the Argentine Confederation, South America, comprehends the Sierra de Cordova and the surrounding hills, and is divided on the N.E., N., and N.W. by the Grand Salinas from Santiago, Catamarca, and Rioja, and on the W. by a travesia, or desert country overgrown with stunted prickly trees from San Juan. A sterile and thinly inhabited country lies on the south-east between it and San Luis. On the south it extends to the Pampas of Buenos Ayres. The low sterile tract in which the rivers Segundo and Primero are lost, and the Laguna Salado de los Porongos is situated, separates it on the east from Santa Fe. It is variously estimated at from 65,000 to 90,000. Cordova is much more fertile than the countries which surround it. Numerous rivers descend from the Sierra de Cordova, but all are lost in the desert, except the Rio Tercero, which, during part of the year, finds its way to the Caracara, which falls into the Paraná near Santo Espirito below Santa Fé. This river would be navigable for six or eight months in the year, but for its small rapids, which however might be easily be bridged. The valleys in the Cordova contain, and those which extend along their sides, have a fertile soil, and maize and fruits are raised there in abundance, but the plains, as well as the declivities of the mountains, are only fit for pasture, and spreading the principal wealth of the republic. Hides in large numbers and wool are exported to Buenos Ayres. At present the produce of this province is all sent to Buenos Ayres, but when steam navigation is opened on the Parana, or on the Paraguay, it will probably be largely carried on through Santa Fé. The province is ruled by a governor, assisted by a junta
Coronado, the capital, is situated in 31° 26' S. lat.; it is built on the banks of the Rio Primero, in a narrow valley considerably depressed below the general surface of the country. This situation is much respected by the climate, and is benefited by the constant movement of cold south winds, which blowing alternately on the higher grounds produce sudden changes in the atmosphere which are injurious to health. The town contains about 15,000 inhabitants. The streets are regularly laid out, and the houses are built of brick, and better than in other towns in the interior; most of them have balconies. In the centre of the town is a spacious square, on one side of which is a neat town-hall, and on the other a fine cathedral. There are also ten other well-built churches in the town, and, like the rest of the province, Cordova is in a very costly manner. The University erected by the Jesuits is on a scale of great magnitude, covering an area of four acres. In former times it was famous, being the principal college (the Colegio Maximo) of the order in this part of the world. It contained also a very important library, which on the expulsion of the Jesuits was sent to Buenos Ayres. The university is still maintained, but is now hardly better than a provincial college. The province of Cordova is divided into three dioceses: the Dominicans and Franciscans. A fine public promenade occupies a considerable space; it includes a square sheet of water of about four acres supplied by a running stream, which is surrounded by walks, well shaded by trees, and has in the centre a magnificent fountain, The Segura. This stream, which is in summer a shallow stream, but in winter becomes a deep and wide river; to preserve the town from the effects of its overflow a strong wall has been built, yet destructive floods still sometimes occur. Cordova was formerly the depot of the European merchandise intended to be sent to Peru, but this branch of commerce no longer exists. There is a mint in the town. The only manufacture is that of leather. There are no foreigners in the town, and scarcely any in the province of Cordova. Religious toleration is unknown to the Catholic and Franciscans and Dominicans. A neck town near the base of the Sierra de Cordova, contains nearly 3000 inhabitants.

Corncake (Oenograsteis). [Rallid.] Cret. Crossbi. [Corac.] Corn. [Cura.].

CORNALL (S. 3?)

Corphonium, a genus of Animals belonging to the class Crustacea and the family Gammarid. With the whole of the family it is remarkable for the length of its antennae. It has no claws. One of the species, Cancer gravipes of Linneus, Gammarus longicornis of Fabricius, Oenica volutator of Pallis, is well known on the coast of Le Rochelle for its habit of burrowing in the sand. They live principally upon the anemones which inhabit the sand, and are remarkable for their power of burrowing in great depth, and destroying it although it may be twenty times as large as themselves. They also attack fishes, molluscs, and the dead bodies of other animals.

Crawley has been a great increase of late years of bodies having many of the characteristics and privileges of Corporations, to which the remarks under Corporation in Penny Cyclopedia, v. viii. p. 46, do not apply.

In effect there are now three distinct species of Corporations—1. Those which may be described as existing at common law, having been generally created by Royal Charter.

3. Trading Corporations.

Under the first head may however be classed those Municipal Corporations, to which the Municipal Corporations Reform Act does not apply, the universities and the colleges therein, and most of the old chartered bodies, such as the College of Physicians, the Companies of London and other cities, and many more of our ancient charitable institutions. These are governed by the provisions of their Charters or Bye-Laws, adherences thereto being enforced when necessary by the Queen's Bench or in Chancery.

The second class of the Municipal Corporations have been treated of under the heading of Corporations by Act of Parliament, having commercial profit for their object. The third class of Corporations is for the purpose of banking or insurance are each regulated by the Act of Parliament, and must each be constituted according to the provisions of these Acts. Other trading companies may constitute themselves into Corporations by registration in a prescribed form, and on complying with certain requisites.

The distinctive ranks of these different kinds of Corporations are noted under the appropriate heads. [Joint-Stock Companies, 2.]

Coriaceous, a genus of Plants belonging to the natural order Rosidceae, of which one of the species, C. alba, is used by the settlers in Australia as a substitute for tea.

Corrientes, one of the Riverine provinces of the Argentine Confederation, South America, comprehends the greater portion of the territory of the present provinces of Paraná and Uruguay; the southern portion of the peninsula being occupied by the province of Entre Rios. The population is about 36,000. The southern and eastern parts of the province are somewhat hilly, and their climate, though in style, and far the greater part is low. About half the surface is covered with timber-trees, much of the wood being available for house and ship-building. Some thousand square miles are covered with palm-trees, which are used for a great number of purposes in the northern part of the province, which is the Laguna Yera, which is in part vast marsh overflowed during the periodical rises of the Parana. It feeds all or nearly all the rivers which rise in the interior of the province and fall into the Parana in the province of Corrientes. Corrientes is generally sandy, but produces excellent crops. Cotton, tobacco, rice, sugar, indigo, and other tropical products flourish, yet little attention is given to them, partly owing to the scantiness of the population and partly to the want of good ports. The principal trade is with Buenos Ayres. Besides the articles mentioned above, maize and barley, arrow-root, melons, sweet potatoes, and various tropical fruits are raised. The sugar-cane is at present only grown in order to extract molasses for distilling; sugar coal and hides are also large imports from Buenos Ayres. All kinds of crops suffer at times from visitations of enormous swarms of ants and locusts, which entirely devastate the districts in which they appear. The chief employments of the inhabitants are in the growing of corn, and in an extensive and considerate extent of good pasturage land; sheep however do not thrive very well. Large numbers of hides are exported. Mechanical pursuits are entirely neglected. The province is well adapted for commerce, there being on the Parana four places which serve as good ports, and three on Uruguay.

The opening of these rivers will doubtless prove of great benefit to Corrientes, but the traffic can only be fairly developed when the rivers are navigated by steam-vessels. The inhabitants are for the most part a mixed race of Indians and Spaniards. The climate has, according to Mr. Woodbine Parish, is "more Guarani than Spanish." There are exceedingly few foreigners in either the capital or the country parts of the province. Most of the population consist of people of mixed race, about an equal number of men and women, from 20 to 40 years of age, and of the age of the sheep, from 100 to 200 sheep. The women are of more industrious habits than the men. They do a good deal of the agricultural labour, as ploughing, hoeing and attending to the crops, and reaping; make cheeses for sale as well as home consumption; make bread and butter; and spin and weave hemp and cotton and woollen cloths for summer and winter garments.

The government is almost entirely in the hands of a governor, who is elected by the Congress for a term of three years. The Congress consists of 18 deputies, one from each of the 14 departments, except the half of the capital, which returns two deputies. The revenue is derived chiefly from customs duties, and the church property which was seized by government during the civil wars. The army consists in time of peace of 2500 men, but of the ages of 14 and 60 are liable to serve. Indeed during the late war with Buenos Ayres a reserve corps was formed of 900 or 1000 women mounted on horseback, who are said to have proved of great service in some engagements with the Spaniards. The combat between the corrientes in the revolt of the other provinces against the supremacy of Buenos Ayres, and entered into the engagements with foreign powers which led to the downfall of Rosas. The main incitements to the rise of the corrientes was the belief of the inhabitants of Rosas in the right of the province of Rosas to the trade and commerce of the Parana and Uruguay against all foreign vessels, and Corrientes made the opening of the navigation of these rivers a leading object in all negotiations. The army of Rosas was defeated in 1825, and the Rosas was defeated by the troops under the command of Corrientes. Rosas himself escaped to Buenos Ayres, and proceeded on board a British steam-vessel to England.
Granada, from which it is divided by a line extending from Point Barúa (about 83°) north by east, to a point a little west of the lagoon of Chiriquí; on the N. it is bounded by the republic of Nicaragua, from which it is divided by the Rio San Juan from its mouth in the Caribbean Sea to the point where it is joined by the others it is joined by the Caribbean Sea, and west of that by the southern extremity of the large island of Cuba. It is bounded on an imaginary line about 11° N. lat., to Salinas Bay on the Pacific Ocean. On the E., Costa Rica is bounded by the Caribbean Sea; on the W., by the Pacific Ocean. Its extreme W. extent is 35 miles, its average breadth about 80 miles. The area is 17,000 miles; the entire population 100,174.

Coast Line, Surface, etc.—Both the eastern and western coasts have a general north-western and south-eastern direction, but the former is more indented, the latter less so. The eastern coast of the Caribbean Sea the coast is bordered by a narrow plain, is little indented by creeks or bays, and affords no large or secure harbour. Ponta Matina (10° 30' N. lat.) at the mouth of the river of the same name, though small and much from safe, is the best harbour on this coast: it serves as the port of Cartago, and is occasionally visited by vessels from the West Indies. The western coast is much more broken. At its southern extremity is the wide open Guilo Dulce, the low shores of which indent the coast so heavily that it is often difficult to determine which falls into it. Further north is Port Manta and, beyond that is the bay formed by the Rio Estrella: neither of these appears to be used by shipping. More important is the Gulf of Nicoya, which is important northward. It has a wide open entrance turned to the south, in which is a narrow narrow inlet. It affords good shelter for shipping, is about 70 miles in length, and contains several islands. Punta de Arenas, on the eastern side of the gulf, is one of the most important harbours of the whole coast, which is more than 10 feet of water. The Punta de Arenas is the port of San José, the present capital of Costa Rica. One other good harbour occurs on this coast, Punta Calabria, which is formed by the rocky headland called Punta Catalina.

The surface of Costa Rica comprises for the most part a table-land with an elevation of upwards of 2000 feet above the level of the sea. From the range of the Caebezas Mountains in the north-eastern part of the Pacific for vessels not drawing more than 10 feet of water. The Volcano of Cartago is said to be 11,480 feet high. Towards the Caribbean Sea the descent is for the most part abrupt, but terminating from 20 to 30 miles from the sea, between which and the bases of the hills is a low, level, and marshy tract, covered with forest and savannah. From the seaside the Pacific the descent is more gradual; while the high land advances much nearer to the sea and descends to it in a series of terraces. A continuous range of volcanic hills extends from the north-western corner of the table-land of Costa Rica to the coastal range of the north-eastern extremity of the country subsides gradually into the plain of Nicaragua.

The only important river of Costa Rica is the San Juan, which is common to it and Nicaragua. It issues from the south-eastern extremity of the Lake of Nicaragua, and from that point to its outlet in the Caribbean Sea forms the boundary between the republics of Costa Rica and Nicaragua. It is a considerable stream and is navigable for some distance, its course is broken by large sand-banks and rapids. From its commencement in Lake Nicaragua to its mouth, the distance, following the windings of the river, is 70 geographical miles. The width varies from 100 to 400 feet. The difference of level between the Lake of Nicaragua and the Caribbean Sea is 121 feet. The commencement of this river and the Lake of Nicaragua, with a canal from the lake to the Pacific Ocean, that it has been proposed to form the Nicaragua line of communication between the seas of the Atlantic and the Pacific. It is said that this line may be met by forming a road about 66 miles long, from San José to the Saragüé, a feeder of the San Juan, and by improving BROC.
the navigation of those rivers, thus enabling the produce of the republic to be shipped at the port of San Juan, and carry its produce to the countries of the Pacific which fall into the Pacific have all a short course. The Andes, the Andes, and the Andes are among the most important. Several small lakes occur on the table-

lance.

Climate, Soil, and Productions.—The climate of Costa Rica is on the whole more regular and healthy than in other parts of Central America. There are two seasons, a dry season, which commences in November and lasts until April, and a wet season which occupies the remainder of the year.

The climate of the Tropics is hot and wet, but in Costa Rica it is cooler, the air is not so heavy and moist, and the weather is more adjustable to human comfort. The temperature ranges from about 70° to 85° below 65°.

In the rainy season thunderstorms of a very severe description are frequent.

The soil is of varied quality, but in many parts very fertile. On the one hand, the soil is light, gravelly, and sandy, on the other hand, the soil is heavy, clayey, and calcareous. The lower declivities, and especially along the eastern coast, are very abundant. A good deal of timber, especially Brazil wood, mahogany, and cedar is exported.

Around the town of Cartago and on the western and north-
western parts of the country, wheat is cultivated to some extent. Maize is grown much more extensively, and is exported somewhat largely to Chili and Peru. Coffee is how-
ever the staple: it is of fine quality, and meets with a ready sale. Tobacco is raised to some extent on the table-land, both for home consumption and exportation. Sugar is an important article in the agriculture of Costa Rica; it is chiefly grown on the western side of the country, and exported from the port of Guanacaste. Cacao, indigo, &c., are also grown. The coffee is chiefly grown on the lower declivities, except the vine, and cochineal, which are by the heavy rains. Agriculture, however, though it is upon its agricultural produce that Costa Rica is chiefly dependent, is in a very backward state, and the capabilities of the soil are very far from having been made fully available.

The most common fruits are apples, pears, peaches, &c. Of vegetables the leguminous kinds, as peas, beans, lentils, &c., are the most common. There are some good pasture lands, and although the Spanish cattle are of inferior breed, there is a good part of the wealth of the country. Horses and mules are bred, but not in large numbers. Swine are raised in the low districts. Sheep are tolerably abundant on the table-land. Poultry are bred in great numbers.

Fish are very plentiful along the coasts and in the rivers. In the Gulf of Nicoya pears and the pearl-

seashells are obtained; also a shell-fish which yields a purple dye.

Several metals are said to exist, but gold is the only one which is worked. The most important gold mines are those of Aquacata not far from the gulf of Nicoya and Real del Monte. Coal is reported to have been found, but it is not worked.

The manufactures are confined to the coarser articles of home consumption. They consist chiefly of coarse cotton goods, common hats, coarse earthenware, furniture, wooden utensils, &c. The commerce appears to be steadily in-
creasing, and consists of coffee, sugar, and some quantities of cotton goods.

The exports are mainly to Europe. The chief exports are coffee, sugar, and some quantities of cotton goods.

The imports into the United States consist of coal, iron, cotton goods, machinery, and some raw materials.

San José, the capital of the republic, population about 16,000, stands on the elevated table-land, 9° 46' N. lat., 84° 8' W. long. Its site is said to be 4500 feet above the level of the sea.

It is a modern city, having grown up since the declaration of independence; and though the seat of the government, legislature, and courts of justice, as well as of the bishop, it has no buildings of any beauty or importance. It is however a busy commercial town. It communicates by a cart-

road 72 miles long with its port, Punta de Arena, which is a thriving place, being the principal port of Costa Rica.

Cartago stands at the base of the Volcano of Cartago, about 20 miles E. by S. from San José; population about 9000. It was once the capital of Costa Rica, and is still a place of some commercial as well as political consequence, but in both respects it has given way to San José. In 1841 it was almost entirely ruined by an earthquake, which destroyed seven out of its eight churches and nearly 1000 houses. It has since been rebuilt.

Alajuela, population, including the surrounding district, about 10,000, stands nearly midway between San José and Punta de Arena, and is a place of some trade. A good deal of sugar is raised in the vicinity. Villa Vieja, about 7 miles W. from San José, is likewise a place of some trade. Curridadab, Asisart, Paraiso, Heredia, Barba, and Esparza, are other towns of more or less consequence.

Government, &c.—The government is in the hands of a provisional government, which has a legislative assembly consisting of 12 deputies elected for three years. The revenue, derived principally from a duty on tobacco and spirits, land sales, stamps, &c., amounts to about 130,000 dollars. The state has no debts to discharge or debts to pay, and is in an internal and external peace for several years. The chief court of justice is the Tribunal of San José, which is presided over by seven judges.

The militia consists of 6000 men, of whom 300 are called upon at a time to form the army on duty.

The white inhabitants of the republic are relatively more numerous in Costa Rica, than in the other republics of Central America: the Indian, or mulatto, are also numerous. They are chiefly settled on the west side of the country, and the remaining population is occupied by the Indians, who number about 10,000.

The Roman Catholic is the established religion, but other forms of worship are permitted. The church is presided over by the Bishop of San José.

During the Spanish occupation of this part of America, Costa Rica formed a part of the kingdom of Guatemala. After the declaration of independence by the Spanish American colonies, September 1821, it remained for a short time united to the Mexican kingdom of Turbe; but when the new federal union of the United States of Central America was established in 1823 after the model of the United States of North America, it formed one of the united states, and by the dissolution of this short-lived union, Costa Rica became an independent republic, and has so continued ever since.

COTIANINA. [CHEMISTRY, S. I.]

COTTON, MANUFACTURE OF. London, Liverpool, and Manchester are the great importations of cotton into this country, especially Liverpool; and the amount of this import is truly marvellous. Liverpool and Manchester often take opposite views of the cotton trade; they stand to each other in the relation of seller and buyer in respect to this commodity; and their interests frequently lead in opposi-
tive directions; but no such difference can affect the real magnitude of the trade. When we consider that Lancashire now contains nearly two millions of souls, that the Glasgow district also contains two millions, and that the Confederation itself has a population of about 300,000, it is apparent that the cotton trade is the chief source of industry in both these districts, and that Cheshire and Yorkshire, together with other counties, also contain their hundreds of thousands of cotton-workers—we can hardly fail to see how extremely important the regular supply of cotton must be to Great Britain.

In our previous article (vol. vii. p. 93) we have brought down the statistics of the supply of this important article to the end of 1839. We have now no occasion to give the details of our former article, and for the present have occasion to give the details of a large growth of supplies for the year 1840, occasioned by the demand for larger supplies of the raw material for which the United States of America are still our chief source, and on the whole it is the best, the cheapest, and the most reliable. But the British manufacturer does not like to depend so much on the United States, particularly for a crop which is so likely to be affected by seasons, and of which the cultivation, which is by slave labour, he apprehends may be some day suddenly interrupted
For many years he has been looking out for places where a future supply may be looked for. But our East India possessions, Brazil, and Egypt (which is made to include Syria and a few other districts of the Mediterranean coast of Asia) have long furnished a portion of his material, but by no means enough to satisfy his wants. The cultivation of cotton has been urged in Australia, the Cape of Good Hope, the West India Islands, and Guyana, among our own settlements; and recently Dr. Livingstone has stated the probability of obtaining a large supply from the interior of Africa with a likelihood at the same time of suppressing the slave-trade by occupying the natives in useful and profitable industry, instead of their barbarous and predatory wars. This, if ever realised, must evidently be a work of time. In our own settlements the price of labour seems on the whole to be too high. It is not the cost of any considerable increase in the quantities we derive from thence; for though there has been a general increase, the supply is very irregular, and it is not large. In the year 1856 the United States supplied 77 per cent., the British possessions 17, Brazil 3, Egypt 2, and other places 6 per cent. of the total quantities imported. A portion, varying from one-sixth to one-sixteenth, is re-exported in the raw state, for most of the European nations are competitors with ourselves in the cotton markets of the world. Hamburg, Amsterdam, Boston, Liverpool, Antwerp, and France (chiefly at Havre) collectively take about two-sevenths of the quantity imported into the United Kingdom. A part of this, as we have said, is sent from England, but on the other hand there is every year imported a quantity of cotton manufactures, such as East India goods, stockings, fringe, yarns, &c., to the value of about £1,500,000, which has not been included in the following statement of the import of raw material, and the declared value of exports from the year 1836 inclusive. We have given occasionally a statement of the sources whence the raw material is derived, as they show the enormous differences of the crops in different places, and sometimes that an insufficient supply from America has been in some measure made up by an increase from other foreign possessions; but we have not thought it necessary to repeat it for every year.

Here was a large falling-off everywhere except in the British possessions, and in "other places," showing the efforts made to procure the raw material. Probably a portion was obtained from the contracted staple, but the cotton manufactures, however, do not appear to have suffered. The following year shows a large increase from the British possessions:

</tr>
</tbody>
</table>

In this year the importations from Egypt, which had been gradually declining, sank to 857,160 lbs., but rose the next year to 65 million, and in 1845 to 114 million.

In this year the duty on raw cotton was taken off, but from a deficient supply the manufacture declined, as also in the following year; nor did it recover itself till 1849.

The prices given for cotton vary greatly. Different countries, different years, different qualities in the same year, all lead to difference of price. Sea Island cotton always realises the best price, while Surat cotton is near the bottom of the list; 1848 was a cheap year, while 1850 was a dear year; the lowest Sea Island (in the beginning of Oct. 1850) was quoted at 8d. per lb., while the highest reached 34d., and Surat was 6d. to 7d. As the very dear cottons are sold only in small quantity, the average price for 1850 was probably about 6d. per lb., and for 1850 about 8d. We give the prices varied at periods, ten years apart, with the latest prices of the so-called Orleans for America, and Fernambuco for Brazil:

The total declared values of the cotton exports for the first eleven months of 1857 are as follows:—Cottons, calicoes, &c., £26,876,922. Cotton yarns, including stockings and cotton thread for sewing, 8,165,905.

A more detailed notice of the sources of production is given in the following statement of the amount of cotton in stock at Liverpool on December 31, 1857: the quantity is stated in bales:

At the same period there were 41,290 bales, chiefly East Indian, in stock in London; and 10,920 in Glasgow, making a total of 422,510 bales.

The quantity of cotton used in the mills of this country does not always show the quantity of work done. The quantity thus consumed was enormously greater in 1848 than in 1847, and a little greater still in 1849; but it is to be remembered that the wages paid, did not increase in a similar ratio. The latter two elements depend in great measure on the weight of cotton used in making a particular size of cloth or yarn. In some states of the market, heavy goods pay the manufacturer better than those of lighter texture; and at such a time the consumption of cotton is increased, though neither the manufacturers' profits nor the workmen's wages may have reached a higher aggregate.

In some cotton factories the material is worth three-fourths of the whole price in some specimens, and only one-twentieth in others. A given number of spindles, employed in making cotton twist of the thickness called No. 20, would use up 1,340 lbs. of cotton, in the time which would suffice to pro-

The demand for cotton is much more strongly felt in respect to coarse goods and yarns; and in fine; so much so, indeed, that the demand for foreign market cotton ceases if the price fluctuates beyond its usual limits; whereas in light goods, wherein labour forms a large part of the selling price, a rise in the price of the raw material is not so sensibly felt. Whenever the supply is deficient and the price high, the manufacturer has an inducement to produce light goods instead of heavy; and for a like reason, when the demand is slack, there is less dead weight of such capital in a stock of light goods than of heavy goods of equal market value.

The account hereinafter to show that we ought not to continue to be so much dependent, as we now are, on the United States for our supply of cotton, are somewhat as follows:—That our yearly supply from other quarters has been constantly increasing, while the supply available for consumption increases in a less ratio, so that it can only be kept up by encroaching on the reserve store; that the United States is the only country where the growth of cotton is materially on the increase, and the increase is not equal in rapidity to the increase of manufacturing or consuming power in Europe and the United States; that no stimulus of price can materially augment the increase of supply in the United States, since the planters always grow as much cotton as the negro population can pick; and that, consequently, if the cotton manufacture of this country is to increase, it can only do so by applying a great stimulus to the growth of cotton in other countries adapted to the culture. Which these "other countries" are to be, is a question whereon much difference of opinion prevails. In the early stages of the cotton manufacture, the countries surrounding the Mediterranean furnished us with nearly our whole supply. In the 15th century the West Indies and the Mediterranean and the West Indies combined furnish a very insignificant ratio. Brazil, Egypt, and India, have successively entered the market; Australia and South Africa have recently done the same. The question arises, of which of the several countries, or whether all combined, can furnish a supply which will materially less our dependence on the United States? The Mediterranean authorities themselves are at issue on this matter; for while some point to the East Indies as the source of an exhaustless supply; others feel reliance only on our own colonies in the West Indies, Africa, and Australia.

Since 1835 there have been no inventions to alter materially the processes of manufacture in cotton, but the improvements in the machinery have greatly facilitated the production in most of the various branches both of weaving and printing.

COTTON COURT. The whole jurisdiction in civil cases of the old solicitors, or County Court ("Penny Cycles", or "Cycles") in England, has been transferred to the County Courts, first established for the recovery of claimants not exceeding £20 in amount, in 1846, but whose jurisdiction has since been considerably extended by 9 & 10 Vict. c. 89; 12 & 13 Vict. c. 101; 13 & 14 Vict. c. 61; 15 & 16 Vict. c. 54; and 19 & 20 Vict. c. 20.

The new County Courts were intended, not only to bring justice to every man's door (like the ancient Saxon tribunals whose place they have taken), but also to supply cheap justice in different localities by as many different Acts of Parliament, obtained for that purpose. These tribunals which were called Courts of Requests, or Courts of Consistence, and were intended solely for the recovery of small debts, were generally consigned to each county or group of counties; 80 counties were established.

The County Court may entertain suits for the recovery of all debts, damages, and demands, legacies, and balances of partnership accounts, where the sum sued for does not exceed £100. If
an abounding debtor, and by statute 17 and 18 Vict. c. 104, a direct writ of gage by collision or otherwise to another vessel to be detained and an absolute misprision for the injury, or security given to abide the event of legal proceedings.

The nature and jurisdiction of the Court have been described thus fully on account of it not being the direct creation of these tribunals, but of the extent and variety of the powers vested in them, and the important position they have taken in the estimation of the people. (Blackstone's 'Commentaries,' Mr. Kerr's edition, vol. viii., p. 36.)

COURTS. The Courts, anticipated in the article on this subject ("Penny Cyclopædia," v. viii. p. 115), took place in 1846, in the re-organisation of the County Courts, with a simple and inexpensive procedure, and a professional counsel in lieu of the sheriff and assessors of the old assize. (Covyre Court, 2, S. 2.) The Court, however, has not been abolished, and provision made for the surrender of the inferior local courts by corporations and the lords of manors and hundreds. Most of these indeed have long been as much in desuetude as the court of consistory.

Many of the more important borough courts have however obtained a renewed vitality, by having the provisions of the Common Law Procedure Acts of 1863 and 1864 extended to them, by order in Council. This has, of course, produced some anomalies. An example of this is the action of Liverpool, where the Mayor himself commanded to enter an appearance at Westminster by the Queen; obliged to obey a like order to appear at Lancaster by the Duchess of Lancaster; threatened with judgment by the justices of Lancashire, and the Mayor of Liverpool, if he fail to appear at the Court of Passport, that town would be, on the 15th of every year, to answer a plaint in the County Court of Lancashire holden at Liverpool. As to the alterations which have been made in the jurisdiction of other courts, see Bankruptcy, 2, S.; Equity, 5, S.; Patent, 2, S.; Divorce, 3, S.

COWPER, EDWARD, was born in 1770. Little or nothing has been published concerning the circumstances and events of the early life of this distinguished inventor and improver of machinery. It is known however that he was a wealthy owner of patents and that Mr. Applegath was induced to build the extensive printing-office in Duke-street, adjoining to Stamford-street, London, now occupied by Messrs. Clowes, and he was a partner with Mr. Applegath in that establishment. They were also connected with machines for grinding corn, and in the construction of new machinery for printing the Times, of which, in conjunction with Mr. Applegath, he published a description. In fact, some of the most important inventions of improvement of machinery are due to him, such especially as the giving a diagonal action to the rollers on the self-acting ink-stands. In the Great Exhibition of 1851 he exhibited a model, made by T. B. Winter, a student in King's College, London, of the printing-machine now in general use. Although the model was not admitted to the Great Exhibition were printed. He had for many years an engagement at the large blacking-factory of Messrs. Day and Martin, in printing their labels in such a manner as to defray a substantial part of the expense. He furnished some contributions to the Penny Cyclopædia, one of which was an elaborate article on a 'Button.'

Mr. Cowper, during some of the last years of his life, was professor of mechanics and manufacturing arts at King's College, and it is as a lecturer that he was best known to the public. His process of imparting knowledge consisted not only in giving descriptions, and illustrating them by models, but in exhibiting the machines themselves, and showing them at work. His manner of lecturing was simple and popular, and he had always a full attendance. His knowledge of machinery, of mechanical construction, and the mechanic arts, embraced the most minute as well as the largest objects. He delivered lectures on the mechanical structure of the Crystal Palace in 1851. He was much respected for his industry, and for the amount of knowledge which he had acquired from his large stores of information to the humblest individuals as well as to persons of higher station. He died at his residence, Kensington, London, October 17, 1855.

COWSLI, JOHN, was born in 1721. He was trained for the bar, but determined to become a merchant. In 1751, he entered into a partnership with Mr. Cradock, and opened a manufactory for making nylons, stockings, and silk gauze. He soon disposed of his interest in the business, and removed to London, where he continued as a merchant until 1766, when he retired from business, and settled down as a farmer at Brixworth, Northamptonhire. He died at his residence, Buckland Park, near Northampton, June 12, 1802.

CRAIG, the uppermost of the distinctly Tertiary Strata of England—using this term in a sense which is perhaps gradually passing away, to be replaced by the larger meaning of Caius. The Crag of Norfolk and Suffolks is partly a calcareous sand, rich in shells; and partly a rudely aggregated deposit of
missions which awaited completion, when he was stricken with a disease—tumour on the brain—which rendered him unconscious. He was taken to the Royal Hospital, the College, and Mammaliferous Crag. The position of these beds will be seen from the following table of the classification of the Tertiary Rocks from Professor Ansted's 'Elementary Geology.'

Newer Tertiary, or Pliocene Series :—
1. Mullock Gravel and Sand.
2. Till.
3. Mammaliferous Crag.

Middle Tertiary, or Miocene Series :—
6. Coralline Crag.
8. Coralline Crag.

CRANBROOK. [Kent.]
CRASSULA, a genus of plants, the type of the natural order Crassulaceae. It has a 6-parted calyx, much shorter than the corolla; sepals flattish; the petals 5, stellate, spreading, distinct; the stamens 6, filamentsawl-shaped; scales 5, ovate, short; carpels 5, many-seeded. The species are very numerous. They are succulent herbs or shrubs, and are mostly natives of the Cape of Good Hope. Their leaves are mostly entire, or dentate, the flower most white, rarely rose-coloured. Upwards of fifty species have been described; and many of them, on account of their grotesque appearance, are cultivated in our gardens. They are greenhouse plants. One species, C. falcata, is used in the drug lists of Hope and Hobbs as a remedy in dysentery. Any medicinal properties they possess is probably owing to the presence of tannin.

CRAWFORD, THOMAS, an eminent American sculptor, was born at New York in the United States on the 21st of March, 1813. At school he obtained some acquaintance with Greek and Latin literature, but, as is frequently the case with youths in his country, he seems to have been allowed in early life to follow very much his own course. Like Chantrey, his earliest interest was in the study of architecture. Whilst with him however his strong desire for higher training began to develop itself. He formed a collection of casts of ancient and modern works of a high class, and he learnt to model in clay. At length he was placed as a pupil under Meissonier. Franez and Lannitz, and entered as a student the academy of design in New York. Mr. Lannitz urged him to proceed to Rome, and gave him a letter of introduction to Thorwaldsen. Accordingly he proceeded to Italy in 1834, and was admitted to the studio of Thorwaldsen, to whose friendship he was greatly indebted. Thrown by the death of his father on his own resources, he for some time supported himself by making busts. The first poetic work of his which attracted particular attention, was the statue of Orpheus, deceased, which he had begun to execute unfinished by an attack of brain-fever, the precursor of his premature fate. On his recovery he completed the Orpheus in marble, a commission having during his illness served for it from the Boston Athenaeum. It excited general admiration and anticipation. He worked on diligently, gaining in executive skill and confidence, and rising steadily in reputation. Among the chief of his earlier works are his "Heroidas with the head of John the Baptist;" "The Babes in the Wood;" "Flora;" and "The Dancers,"—two life-size statues of children, which have had considerable popularity. Among the best of his later works are his bronze statue of Beethoven, now in the Athenaeum at Boston, America; the equestrian statue of Washington which stands at Richmond, Virginia; and the more ambitious alto-relievo of the "Progress of Civilisation in America," which he was commissioned by the federal government to execute for the pediment of the Capitol at Washington. Others of his works are his statues of The Genius of Mirth at Richmond, Virginia; and "Prayer;" his groups of "Adam and Eve," of heroic size; "A Family suffering under the plague of Fyery Serpents;" "A Mother attempting to save herself and Child from the Devil," and his life busts of Sappho, Vesta, &c. He also made numerous designs for bas-relief illustrative of the Old and New Testaments; the poets of Greece, Italy, and England; events of American history, &c., as well as several models of leading American statesmen.

For some years Crawford made that city his home. He had just completed a new and spacious studio, in order to work with more convenience at the numerous com-
Croker, Right Honourable John Wilson, was the representative of a branch of an ancient family which was settled for many generations at Linenham, in South Devon. A member of this family emigrated to Ireland about the year 1600, and his sons distinguished themselves at the capes of Ireland. One of these branches received grants of land in the south of Ireland, which they increased from time to time by marriages with influential families. Mr. Croker, the father of the subject of our present memoir, was for many years surveyor-general of Ireland, and was a considerable portion of the present State. By his marriage with Hester, daughter of the Rev. R. Rathborne, he had an only son, John Wilson Croker, who was born in Galway, December 20, 1790.

After receiving his early education at a school in Cork, where he displayed great probity and an inquisitive disposition, he was entered at Trinity College, Dublin, at the age of sixteen, under the late Dr. Lloyd. He soon began to show extraordinary readiness and ability by the part which he played in the debating society, in which he was much pressed, but which then was in active operation, drawing out and developing the characters of young men, and preparing them for their appearance afterwards on the stage of public life. So highly did the society esteem the share taken in its proceedings by Mr. Croker, that it voted him its first gold medal. Intended by his parents for the study of the law, Mr. Croker had no sooner taken his B.A. degree in 1800, than he was entered as a student at Lincoln's Inn; but he continued to reside in Dublin, and to mix with the society of the college, with whom he spent the greater part of his leisure hours on his hands, and these he devoted to literature. His first production as an author, if we except a short paper of mere ephemeral interest, was a series of 'Pamphlets on the Present State of the Irish Stage,' which was published in 1803, and was followed in 1805 by his 'Intercepted Letter from China,' both anonymously. Both were clever and caustic satires, excited much curiosity and attention, and ran speedily through several editions.

In 1807 he published a work of a graver kind on 'The State of Ireland, Past and Present,' in evident imitation of the treatise of Tacitus 'De Moribus Germanorum.' In this pamphlet he strongly advocated Catholic emancipation. At the close of the preceding year Mr. Croker was employed as counsel for Sir Josias Rowley, at the election for Downpatrick. Sir Josias withdrew just before the election, and Mr. Croker was nominated in his place, but was defeated by a small majority.

In the following May however he was returned for the borough, and confirmed in his seat on petition. He had not been long in parliament when an opportunity offered for the display of his oratorical powers. Early in 1809 the Duke of York was brought practically upon his trial, having been committed to the custody of the Herse Guards, and the best and most successful speech made in defence of his Royal Highness against Colonel Wardle's motion of censure, was delivered by Mr. Croker on the 14th of March. This speech contained a minute dissection of the evidence in the case, and was couched in vigorous and pointed language. It may be presumed that the grateful sense which his Royal Highness thenceforth entertained for this support hastened the advance of Mr. Croker to office. In the course of the same session the late Duke of Wellington, then Sir Arthur Wellesley, and chief secretary for Ireland, being obliged to repair to Dublin, entrusted to Mr. Croker the parliamentary business connected with the affairs of that country. With that confidence and ability and discretion, that shortly afterwards Mr. Perceval, when he formed his ministry in 1809, offered to Mr. Croker the post of Secretary to the Admiralty. For upwards of twenty years Mr. Croker continued to discharge the duties of that office with zeal and acceptability. He was one of the First Lords of that department, and under King William IV. when Lord High Admiral. During this time he sat in parliament for various boroughs; amongst others for Aldborough, Yorkshire, in 1829, and in 1832, was one of the subscribers in the subscription of being returned for the University of Dublin, over against the residence of Lord Plunket to the chancellorship and peerage, with whom he had twice unsuccessfully contested the seat: but his views being in favour of Catholic emancipation, Mr. Croker was at last defeated. He took a very active part in the parliamentary committee appointed to consider the question of erecting New London Bridge; and his zeal for science and literature was shown in another way soon afterwards, by founding the Athenaeum Club. He was amongst the earliest advocates of a state encouragement of the fine arts. His speech on the proposed purchase of the Elgin marbles was much in advance of the general tone of parliament on such subjects. When the Reform Bill was in its last stages, Mr. Croker opposed it at every stage by powerf ul speeches and a ready pen, as he considered it a revolutionary measure.

The passing of the Reform Bill compelled Mr. Croker to withdraw from parliamentary life. Even during the most important of his political movements, he never lost his idle employment. His printed speeches and pamphlets on current political questions amount to a very considerable number, and his contributions to the 'Quarterly Review,' extending over more than a quarter of a century, would alone fill several volumes. In 1856, under the title of 'Life of Johnson,' in 4 vols., 8vo, published in 1851, which was handled with considerable severity by Mr. Macaulay in the 'Edinburgh Review.' His poems of 'Ulm and Traflagar,' and 'Life of Shadwell,' among the number of his productions in verse. His 'Stories from the History of England' is a highly popular book for children. The following is a list of the most important works not mentioned above, which were either published or edited by Mr. Croker: 'A reply to the Letters of Malachi Malagrovetz, on the Military Events of the French Revolution of 1830;' 'Letters on the Naval War with America,' and 'Songs of Traflagar.'

He was also the author of several lyrical poems of merit, including some touching lines on the death of Mr. Canning, one of which has appeared in a later edition of his 'Suffolk Papers,' 'Lady Hervey's Letters,' 'Lord Hervey's Memoirs of the Reign of George II.,' and 'Walpole's Letters to Lord Hertford.' He died August 10, 1857.

Mr. Croker was the only son of Major Thomas Croker, of the 38th regiment of foot. At the age of fifteen he became an apprentice in a mercantile establishment in Cork. Between the years 1812 and 1818 he made excursions occasionally on foot in the south of Ireland; and it was during these rambles that he commenced making his collections of the legends and songs of the peasantry in Ireland. In the year 1816, Moore, in an advertisement to the 7th number of the 'Irish Melodies,' expressed his obligations to Croker for a collection of the sweetest and most classical fragments of Irish poetry, for several interesting local traditions. Crofton Croker also had considerable skill in making pen-and-ink sketches, and one of them was exhibited at Cork in 1818.

Major Croker died in 1818, and his widow soon afterwards made application to Mr. John Wilson Croker, then secretary to the Admiralty, who was a friend of the family, but no relation; and through his interest in February, 1819, Thomas Croker Croker was permitted to enter the navy under a contract with a salary of 2£. a week. While in this situation he contributed to the introduction of lithography into the Admiralty as a substitute for transcribing several copies of the same document, and his skill had for many years the superintendence of the private lithographic press of the Admiralty. He subsequently became a clerk of the first class, with a salary of 80£.; and he retired in 1850 with a pension of 86£. Mr. Crofton Croker's first literary work was his 'Researches in the South of Ireland,' published in 1894, in 4to, and con-
sitting for the most part of the notes made during his early experiments, 1832, and during a subsequent tour in 1833. His next work was the 'Fairy Legends and Traditions of the South of Ireland,' London, 1836, 3 vols. 8vo. In the first edition of this work he was assisted by Dr. Maginn, Mr. Pigott, and Mr. Keightley; but the materials supplied by his assistants, or at least most of them, were afterwards omitted. A second edition was illustrated with etchings, after sketches by Maclise, then, as Croker states, 'a young Irish artist of considerable promise.' The 'Fairy Legends' appeared in 1834 in one volume, forming a part of the 'Pen and Pencil' series, which he in 1837 produced a long complimentary letter from Sir Walter Scott; and on the 20th of October 1836, he was introduced to Sir Walter at the residence of Mr. Lockhart in Pall Mall. His name was written down in his visitor's diary. — Little as a dwarf, keen-eyed as a hawk, and of easy-possessing manners, something like Tom Moore.'

In 1839 Mr. Crofon Croker published 'Legends of the Lakes, or Sayings and Doings at Killarney,' collected chiefly from the manuscripts of R. Adolphus Lynch, Esq., H.P. King's German Legion, 'London, 2 vols. 8vo. This work was followed in 1839 by two small novels—The Adventures of Barney Mahoney,' and 'My Village versus Our Village,' of which the first was very favourably received, but the second not so much appreciated, with very copious notes. The Popular Songs of Ireland,' 1840, was a contributor to some of the annuals which were in fashion from 1839-40, especially to 'The Amulet,' and 'Friendship's Gift,' for two years in succession, or at least a year and a half. He wrote many small articles, some for magazines, and some which were printed privately. He was a constant contributor to the early volumes of 'Fraser's Magazine,' frequently to 'The Literary Gazette,' and occasionally to 'The New Monthly Magazine.' He had always a separate table for antiquities, and he was early elected a Fellow of the Society of Antiquaries. He was chosen a member of the Royal Irish Academy in 1847. He took part in the foundation of the Camden Society in 1839, and of the Percy Society two years later, and was one of the joint editors of these societies, and he edited some of the works published by them. When the British Archæological Society was founded in 1843, he became one of the committees. He was also a member of the United Service Institution, of the Irish Archæological Society, of the Numismatic Society, of the Hakluyt Society, and he was perpetual president of the club of antiquarians called the Society of Novicians. He had collected an extremely interesting museum of Irish antiquities, and he was acting director of it. He lived at his residence, Old Brompton, London, August 8, 1864.

CROMFORD. [Derbyshire.]

CROSI. [Mineralogy, No. 1.]

CROSSE, ANDREW, a celebrated lecturer on electricity and chemistry, was born at Farnham, in the parish of Bromfield, on the Quantock Hills in Somersetshire, on June 17, 1774. His father was the proprietor of the estate, to which he succeeded in 1800. He was educated at the school of the Rev. Mr. Bayes, at Bristol, where he had for school-fellows W. J. Broderip, the Rev. John Eagles, and other equally celebrated men. In 1809 he matriculated at Brasenose College, Oxford, where he was very uncomfortable, the habits, especially that of drinking, being particularly unsuited to him. He returned home in June 1809, on account of the illness of his mother who shortly afterwards died. Even when at school he had become greatly attached to the study of electricity, and on settling on his paternal estate he devoted still more of his attention to it. He provided himself with electrical apparatus, and pursued his experiments wholly independently of theories, and searching only for facts. In a cavern near his residence, called Holwell cavern, he observed the sides and roof covered with arragonite crystallisations, and his observations led him to account for the illness of most of them, were afterwards the effects, at least to some extent, of electricity. This induced him to make the attempt to form artificial crystals by the same means, which he began in 1807. He took the lead of the crystal from the cave, filled a tumbler, and exposed it to the action of a voltaic pile for about a week, the pile alone, letting the platinum wires of the battery fall upon opposite sides of the tumbler from the opposite poles of the battery. After ten days of constant action he procured crystals of all the same substances by altering the arrangement he produced them in six days. He found however, that darkness was essential to the certainty and rapidity of their production. He carried an insulated wire above the tops of the trees around his house, to the length of a mile and a quarter, afterwards shortened to a distance of 1,800 feet. By this wire, which was brought into connection with his apparatus in a chamber, he was enabled to see continually the changes in the state of the atmosphere, and could use the fluid so collected to advantage. At a meeting of country gentlemen, he prophesied 'that, by means of electrical agency, we shall be able to communicate our thoughts instantaneously with the uttermost ends of the earth.' But though he foresaw the powers of the medium, he did not think it possible to understand his own prophecy, or even made any experiments in that direction; he continued to confine himself to the endeavour to produce crystals of various kinds, in which he eminently succeeded. After selecting carbonic acid, crystals, or minerals uncrystallised,ption in the form in which they are produced by nature, including one, sub-sulphate of copper, an entirely new mineral neither found in nature nor formed by art previously. His belief was, that even diamonds might be formed in this way. Still he worked alone; he published none of his experiments to the world, and he pronounced no theories. At length, in 1836, the British Association for the Advancement of Science held its meeting in Bristol, and Mr. Crosse attended it, intending to be an onlooker only. He was invited by the president and some of the scientific gentlemen there, he was induced to explain them publicly, and though unprovided with apparatus, they were so struck with the importance of what he, that he was publicly directed to apply to the government for proper means. He applied and by Dr. Buckland, Dr. Dalton, Professor Sedgwick, and others. A few months after this meeting, while pursuing his experiments for forming crystals from a highly caustic solution out of contact with atmospheric air, he was greatly surprised by the appearance of an object. It was a small, reddish and reduced to powder, was mixed with carbonate of potash and exposed to strong heat for fifteen minutes. The mixture was poured into a black-lead crucible in an air furnace. It was reduced to powder while warm, mixed with highly caustic carbonate of potash, and afterwards added a few drops of hydrochloric acid was added to supersaturation. After being exposed to voltaic action for twenty-six days a perfect insect of the Acari tribe, made its appearance, and in the course of a few weeks about a hundred more. The experiment was repeated in other chemical fluids with the like results, and Mr. Weeks, of Sandwick, afterwards produced them in ferricyanur of potassium. This discovery occasioned great excitement at the time. The possibility was denied, though Mr. Crosse and others were directed to him in a similar appearance in his own electrical experiments; and he was accused of impertinence, as aiming at creation. He was much hurt by these attacks, for he was a truly pious man. He says he was inclined to believe that the insect was formed from hydrogen, water, but had since abandoned this view; and adds, 'I have formed no visionary theory that I would travel out of my way to support.' He attempted to give no explanation of what he admitted he could not comprehend, the chief of which was, that he were giving him "a reviver of our holy religion," he replied that he was sorry if the faith of his neighbours depended on the claw of a mite. These insects, if removed from their birthplace, live and propagate, but uniformly die on the first recurrence of water, and are entirely destroyed if they fall back into the fluid whence they arose. This was the most remarkable of his discoveries; but his labours were in some instances more useful. He invented a method, which was patented by others, for purifying sea-water by electricity, which water possesses a similar property to that of arragonite; he was also capable of being used for the improvement of wines, by removing the predominance of bitartrate of potash; to the improvement of spirits by removing acidity; and to the destruction of crystals. In these experiments, he made many experiments of the effects of electricity on vegetation. He found that positive electricity advanced the growth, as was shown by the cultivation of two vines by Mr. Boys of Margate; and that negative electricity favoured the growth of fungi, and was employed for the purpose of drying plants. In this branch of his researches, Mr. Crosse did not confine his labours to scientific matters. Though living chiefly on his estate in the country, he took an earnest part in all local affairs. He was an active magistrate, just, but benevolent; he advocated the instruction of the poor; and gave money on various occasions to the neighbouring institutions; he left a quantity of poetry, com-
CRO

CUB

assembled above mediocrity, which he could not be induced to publish in his lifetime, but which has been given to the world by his widow, in a memoir of him written with much good taste; and he died, after a short illness, July 6, 1850, leaving behind him the character of a pious good man, and an indefatigable searcher for truth.

CROCKETT, WILLIAM, Doctor of Music, was born in 1775, in a city on the borders of the Thames. While yet a child, he exhibited unusual facility of musical reception, and his performances were quite marvellous, and rival those of Mozart. An account of his precocious talents was given by Dr. Burney, author of the 'History of Music,' and is printed in the 'Philosophical Transactions' for the year 1776. He composed all his works in his four years of age. Some anecdotes are also extant, written by the Hon. Daines Barrington, who says, "I first heard little Crotch on the 10th of December, 1778, when he was only three years and a half old." The following notices are extant from memoranda which he made on returning home: "Plays 'God save the King' and 'Minuet de la Cour' almost throughout with chords; reaches a sixth with his little finger; cries 'no,' when I purposely introduced a wrong note; delights in chords and running notes for the base; plays for ten minutes extemporary passages, which have a tolerable connection with each other; seldom looks at the harpsichord, and yet generally hits the right intervals, though distant from each other. His father is an ingenious carpenter, and very musical, as is the case with a great deal of our country music, instead of being the work of a hard coach. Many of his passages hazzarded and singular, of which he executed by his knuckles, tumbling his hands over the keys. The accuracy of this child's ear is such that he not only pronounced immediately what he had heard, but also what he saw on the music, and he immediately repeated the whole down the memory."

As Crotch advanced in years he became a profound theorist and a skilful composer. In 1797, at the early age of twenty-two, he was appointed Professor of Music in the University of Oxford, and the university also conferred on him the degree of Doctor of Music. In 1802 he was appointed Principal of the Royal Academy of Music. He performed in public for the last time in 1834 in Westminster Abbey, during the royal coronation, when he presided at the organ on the third, the last, and in a large number of pieces for the harpsichord, pianoforte, the organ of 'Palestine,' and some pleasant vocal pieces, among which may be mentioned the fine ode for five voices, 'Mona on Snowdon calls.' He also published 'Elements of Musical Composition and Oratorio, 1812,' and 'Specimens of various Styles of Music of all Ages, 3 vols."

Crockett, during the latter years of his life, resided at Taunton, Somersetshire, with his son, the Rev. W. R. Crotch, master of the free grammar-school. He died December 20, 1847, in his sixty-third year. He was the author of several works on music, and is remembered as one of the most eminent composers of the English school.

CROZIER, CAPTAIN FRANCIS RAWDON MOIRA, second in command of the ill-fated Franklin expedition, was born at Banbridge, county Down, Ireland. He entered the navy in June 1810, and in 1813 was appointed to the chief command of the 'Erebus.' He was appointed to the command of the 'Erebus' and 'Terror' in 1819, and commanded the expedition to the Arctic regions. In 1823, he was appointed to the command of the 'Erebus' and 'Terror,' and sailed with Franklin to discover the North-West Passage; since which time he has not been heard of. He was in the prime of life on his departure, and died probably in his fiftieth year. He was a fellow of the Royal and Asiatic Societies, and was celebrated as much for his devotion to duty as for his love of science.

CUDEN, ALEXANDER, the author of the well-known Concordance, was born at Aberdeen in 1701. He studied at Marischal College, but whilst there, his conduct was marked by a certain principle of independence, which secured his promotion; and he commanded the Terror in the expedition under Sir J. Ross for the exploration of the Arctic regions, which sailed in 1839, and was absent three years. In March 1845 he was re-commissioned to the Terror, and sailed with Franklin to discover the North-West Passage: since which time he has not been heard of. He was in the prime of life on his departure, and died probably in his fiftieth year. He was a fellow of the Royal and Asiatic Societies, and was celebrated as much for his devotion to duty as for his love of science.

CUDEN, Dr. Moncreif, Matthew Wright, John Oswald, and John Davis, defendants, in the Court of Common Pleas, in Westminster Hall, July 17, 1739, on an action of trespass, assault, and imprisonment . . . with an account of several other Persons, who have been most unjustly confined in Private Madhouses. The whole tending to show the great necessity there is for the Legislature to regulate Private Madhouses in a more effectual manner than at present, st, v, in 1739. Cuden appears to have been treated while in the asylum with great cruelty, not only by the medical man, by the reader of printers' proof-sheets, and in the occasional preparation of indexes. Among others he is said to have compiled the elaborate index to Newton's 'Milton.'

His first novel was a strange kind of autobiography, under the title of 'Adventures of Alexander the Corrector.' A second time it was deemed necessary to place him under temporary restraint at Chelsea; and again he brought an action in the Court of King's Bench for false imprisonment, and was succeeded in his case to his own satisfaction as before. On obtaining his liberty he quietly returned to his ordinary occupations. Subsequently he published the second part of his Adventures, in which he gave a vivid and harrowing picture of confinement, or 'Chelsea Campaign,' as he calls it in his title-page; and in this trial, and endeavoured in vain to obtain an audience of the king, in order to present a copy of the two parts. He also, as he says, 'pleaded very hard that the honour of knighthood might be conferred upon his son, with an offer to fulfil the prophecy about being made a member of parliament for the city of London.' He seems to have actually got himself nominated (April 30, 1764) as a candidate for the city; but he acknowledges that few hands were held up by the public. He is the author of 'Cuden's Adventures, in which he relates the ill-success of a motion he made in person for a new trial; of his applications for knighthood, and for admission into the House of Commons; and the curious results of his History of the Love Adventures, with his Letters, &c., sent for his safety by Whitaker, a lady of shining character and of great eminence,' in which he was as unlucky as in other matters. Impressed with a belief that he had a mission to reform the public manners, he went to preach to the prisoners in Newgate, and then made a journey to Oxford in order to preach to the students at the university. Disguised at the reception he met with, he abandoned preaching, but arming himself with a large sponge, he went about the streets removing any writings or sayings which appeared to him to be in favor of the vice and of the frivolous, and when the affair of Wilkes and No. 46 of the 'North Briton' was exciting so much public ire, his loyalty led him to the active use of his sponge in effecting the offensive number. His insanity seems to have expanded itself in this harmless manner. He continued to pursue his ordinary employments, and found time to enlarge and revise his Concordance. He also published 'Alexander the Corrector's Humble Address;' and other pamphlets relating to the communication of the American discoveries, marked by strong indications of insanity. He died at Ipswich in November 1770. Cuden's 'English Concordance' was far more complete and valuable than any preceding one, and it still retains its value. Three editions of it were published during Cuden's lifetime, and it has since gone through innumerable editions of all degrees of correctness: one of the most esteemed is that of 1815.

CUBITT, THOMAS, was born in 1788, and was the son of a labouring man at Buxton, a village in Norfolk. Thrown
CUC 164  CUM

early on his own resources, and denied the advantages of what is called a liberal education, he nevertheless rose into eminence by skill and industry combined with integrity, and amassed a large fortune by the improvements he effected in the architecture and sanitary arrangement of London. His father died while he was still a youth. The trade to which he was brought up was that of a carpenter. He went to sea for some time, and then went to India in the capacity of ship's carpenter. Having ac-

2. Skiddaw Slate, usually without fossils, but containing Graptolites, occurs in one locality.

3. Coniston Flagstone and Grit. These rocks find their representatives in those called Cambrian slates in North Wales, and Skenfrith rocks in Herefordshire. Sir Roderick Murchison in his 'Sillarian System.' As the nomenclature of these rocks is still a disputed question, we subjoin the account of them published by Mr. Jukes, in his work on 'Physical Geology.'

'Cambrian or Cambrian Rocks.'—The word 'rocks' is used here instead of 'system,' or 'formation,' because we cannot yet precisely tell the value of the Cambrian division. Cambrian means the rocks of Wales; Cambrian those of Cumberland and Westmorland. In Wales those rocks contain species of fossil which are unknown in England, and resembling, with interstratified beds of green and purple slates. It is in the uppermost of the slate beds of this Cambrian group that the great Phrynix and Llanberis slate occur. In England, there are only two beds which occur, one in the 'Corrib,' and another in the 'Llanberis.' Their upper boundary is a purely arbitrary line along the top of a certain set of beds drawn by the officers of the Geological Survey of Great Britain, under the direction of Sir H. De la Beche, C.B., for their reason for drawing it being simply that no fossils have as yet been found below that line, whereas fossils are pretty abundant in many places above it. It must not be forgotten that Professor Sedgwick (of whose peculiar department we are now speaking, he being the one geologist who has single-handed done far the most to unravel the structure of these older rocks) dissent from this placing of the boundary of the Cambrian Rocks; and himself places it much higher, so as to reach the upper horizon. This shall be called the 'Silurian.'

Cuckoo Flower. [Cardamine, N. 1.]

Cullen, Scotland, a royal and parliamentary burgh and seaport in the parish of Cullen, on the northern coast of Banffshire, in 57° 49' N. lat., 2° 50' W. long., about 134 miles north of Edinburgh. The town, or borough as it was called, was a royal burgh in 1581, and had the right of common bailiwick. The town is built on the western acclivity of a hill which slopes to the margin of the sea, and is nearly in the centre of the Bay of Cullen. The burg is garrisoned by 19 council-

CUMBERLAND Limestone, abundant in fossils.

CUMBERLAND Flagstone. These rocks occur in the district of the Cumberland, and are known in the localities of Skiddaw Slate, and Graptolites, occurs in one locality.

CUMBERLAND rocks. The succession of rocks, as pointed out by Professor Sedgwick in the Cumberland hills, is as follows:

1. Skiddaw Slate, usually without fossils, but containing Graptolites occurs in one locality.

2. Coniston Limestone, abundant in fossils.

3. Coniston Flagstone and Grit. These rocks find their representatives in those called Cambrian slates in North Wales, and Skenfrith rocks in Herefordshire. Sir Roderick Murchison in his 'Sillarian System.' As the nomenclature of these rocks is still a disputed question, we subjoin the account of them published by Mr. Jukes, in his work on 'Physical Geology.'

'Cambrian or Cambrian Rocks.'—The word 'rocks' is used here instead of 'system,' or 'formation,' because we cannot yet precisely tell the value of the Cambrian division. Cambrian means the rocks of Wales; Cambrian those of Cumberland and Westmorland. In Wales those rocks contain species of fossil which are unknown in England, and resembling, with interstratified beds of green and purple slates. It is in the uppermost of the slate beds of this Cambrian group that the great Phrynix and Llanberis slate occur. In England, there are only two beds which occur, one in the 'Corrib,' and another in the 'Llanberis.' Their upper boundary is a purely arbitrary line along the top of a certain set of beds drawn by the officers of the Geological Survey of Great Britain, under the direction of Sir H. De la Beche, C.B., for their reason for drawing it being simply that no fossils have as yet been found below that line, whereas fossils are pretty abundant in many places above it. It must not be forgotten that Professor Sedgwick (of whose peculiar department we are now speaking, he being the one geologist who has single-handed done far the most to unravel the structure of these older rocks) dissent from this placing of the boundary of the Cambrian Rocks; and himself places it much higher, so as to reach the upper horizon. This shall be called the 'Silurian.' It is highly probable that the Skiddaw Slates are of the same age as the Barmouth and Harlech Sandstone Group of North Wales, which likewise contains the best roof-slates of that country.

Cumbrian, Upper (Coniston Flagstone . . . . . 1500

Cumbrian, Upper (Coniston Limestone . . . . . 300

Cumbrian, Upper (Slates and Porphyry . . . . . 10,000

Cumbrian, Lower (Skiddaw Slate . . . . . 4000

He describes these however as all fossiliferous, which, by the rule lately mentioned, would exclude them from being considered as Cambrian at all, more especially as the fossils of the upper beds are such as palaeontologists seem agreed have consider of Silurian age. It is highly probable that the Skiddaw Slates are of the same age as the Barmouth and Harlech Sandstone Group of North Wales, which likewise contains the best roof-slates of that country.
defence, a renegade soldier, a drummed-out dragon; a dull followed, when he declined returning Mr. St. Leger's visit, and the court was not invited. He had been always a warm politician, and in 1785 he returned to the court of Kilbeggan, on the interest of a Mr. Longfellow. As a representative of the state of the Irish parliament, we may mention that soon after entering the House of Commons he found himself on the side of the aristocracy, to which he sat, and he had no way of vacating his seat he coolly offered to buy another seat, to be filled by any one Mr. Longfellow might choose to appoint. That gentleman declined the offer; but in the succeeding parliament Mr. Curran bought a seat for the adult part, generally acting with Mr. Grattan and the few liberal members who then sat there. His speeches were of a very characteristic nature, to those made at the bar, and he was often appointed to make the reply from his readiness to answer a hurry, without the least regard for the opinions of his opponents. He supported the formation of the Irish Volunteers in 1778, and the unconditional appointment of the Prince of Wales to the regency on the occasion of the king's illness in 1789, and his attacks on the government led to a duel, first with Mr. Fitzgibbon, afterwards Earl of Clare, and then with Major Hobart, in which Mr. Curran was the challenger, in both of which neither party was injured. It was in 1784 and the few subsequent years that Mr. Curran's greatest reputation as a debater. In 1799 he was impeached for seditious libel issued in the form of an address to the volunteers of Ireland from the society of United Irishmen (not the same as the rebellious societies which afterwards took this name), from which he was exonerated. Mr. Curran was his cousin, and made an eloquent and vigorous speech, but Mr. Rowan was convicted and sentenced to imprisonment; and after the breaking out of the rebellion in 1798 he was the counsel generally employed by the accused, among whom the most remarkable were the two brothers Sheares, Theobald Wolfe Tone and Thomas Francis McDonnell. He had retired from the Irish House of Commons before the introduction of the measures for the Union, of which he strongly disapproved, and which he ever continued to lament. The dissension of 1803 brought trouble into his family; Robert Emmet, one of its leaders had formed an attachment for Miss Sarah Curran, which was returned; and his correspondence with her, with his visits, sometimes secret, to her father's house, led to a suspicion of Mr. Curran's loyalty, and to the searching of his house. He was charged with treason by Standish O'Grady, and the privy council, by all of whom his perfect want of complicity was instantly admitted. Mr. Emmet had named him one of his counsellors, but he did not appear before Mr. Emmet, who was arrested, on his fate and his love adventures the subject of two of Moore's Irish Melodies. Upon the death of Mr. Pitt, in 1806, the Whig ministry under Lord Grenville created Curran Master of the Rolls in Ireland. This appointment did not give him satisfaction; it withdrew him from politics, and as his mind was not judicial, he felt himself out of place: he thought he had been neglected, and his health declined. He held the office till the early part of 1813, when he resigned; and he died in London on October 14, 1817. Mr. Curran in the course of his life wrote a considerable amount of verse of more than ordinary merit, but which bears no comparison with his eloquent speeches.

CURSORIT BARON. This office, or rather sinecure, was abolished by the statute 19 & 20 Vict. c. 86, which also makes provision for the performance of its almost nominal duties.

CUSHAT (Columba diopho). [COLUMBIDE.] CYAMELIDE. [CHEMISTRY. S. 2.] CYANAGROCHE. CHLORIDE OF. [CHEMISTRY, S. 1.] CYANIC ACID. CHLORIC ACID. CYCLADID, a family of fresh-water mollusks, which shells resemble those of *Koilia* or *Astarea*, but whose soft parts present actual structural characters of a genus distinguishing them from the tribes to which either of those genera belongs. The shells are more or less tumid, equilateral or inequilateral, thin, as in our British forms, or thick, as in the foreign *Cyclo;* smooth or concentrically striated and furrowed, and covered with an epidermis. The bivalva is furnished with cardinal and lateral teeth, and the ligament is external.
The animals have plain-edged mantles open in front, siphonal tubes produced, and either partially separated or completely united to their unfringed extremities, and a large longiform foot. They live buried in the mud of slow streams, lakes, ponds, ditches, and springs. Our native species are all evo-

viviparous. They breed readily in confinement, and often exhibit considerable activity, ascending the sides of the vessel in which they are placed. (Forbes.) This family contains two British genera, Cylas and Pinctada. Cylas has the shell equivale, thin, subboricular, more or less inflected, slightly inequilateral, closed, smooth, or concentrically striated; cardinal teeth, one in the right and two in the left valve; lateral teeth developed; ligament external.

C. rivicola has the shell oval, globose, striated; umbones obtuse; dorsal area with a small tubular impression; ligament external.

The ordinary length of the finer specimens is 10½ lines, and its breadth about two-thirds of an inch. The tubes of the animal are tinged with rose or tawny, and when fully protruded are nearly equal, the branchial, if either, being longest.

The foot is large, white, and longiform; the mantle white; the labial palps long, triangular, and strongly striated. It is sluggish in its habits.

Forbes and Hanley give the following localities:—The mussels are common in the river Thames; it is found likewise in the New River (Baily); the Trent (Jenyns); the Lea (6. H.); the canals near Leamington, in Warwickshire (Thompson); streams in Yorkshire (Dean). In a pond at Enville, Stafford-

shire, young specimens (Jeffreys). It has not been taken either in Scotland or Ireland. On the continent it occurs in Germany, France, and Belgium; and as a fossil is found in the Pleistocene Fresh-Water Beds of the south of England.

C. cornes, Linn. Shell subglobular, almost smooth; umbones obtuse; ligament inconspicuous. There is a subglobose variety (apparently the Stigmocila of Mr. Sheppard), which is flattened towards the ventral margin, and has the pellicul and swollen umbones peculiarly prominent. The dimensions of the larger typical form are six lines and a quarter in length, and five lines in breadth; of the variety five lines and a half in length, and four and three-quarters in breadth.

The animal is white, its sub-elongated siphonal tubes tinted with pale flesh-colour. Mr. Jenyns observes that the superior tube is sub-conic, with a small aperture, the inferior cylindrical and truncate, with a wider aperture.

This very common species is a general inhabitant of rivers, ponds, and ditches throughout the country. It appears to thrive equally well both in running and in stagnant water. (Jenyns.)

It is also generally distributed throughout Europe, and occurs fossil in fresh-water strata of the pleistocene age in the valley of the Thames. C. calcarea has the shell more or less rhombic; umbones narrow, more or less prominent, capped.

This species is apparently less frequent in the north than in the more southern parts of England. Mr. Alder has found it near Newcastle; Mr. Bean at Scarborough (where it is not scarce); Mr. Thompson at Lichfield; and Captain Brown records the vicinity of Manchester and the lakes of Westmoreland for its localities. Montagu met with it in Devonshire and Wiltshire; Mr. Jenyns at Braham Common in Surrey, and more sparingly in Cambridgeshire; and Mr. H. Strickland at Hernsea in Yorkshire. Mr. Jeffreys has taken it in the Clumber Lake, Nottinghamshire, and in the neighbourhood of Bristol. In Ireland it is also rare.

On the Continent it occurs in Sweden, Germany, Belgium, France, and Italy. The C. portumnae of Say, in despite of the ventricosity of the adult, is very closely allied, especially in outline, to this species, and may be regarded as its transatlantic representative. (Forbes and Hanley.)

Pinctada has the shell equivale, thin, usually tumid, sub-oval, inequilateral, smooth or concentrically striated; hinges with one tooth in the right and usually two in the left valve; also lateral teeth; ligament external, inserted at the shorter side.

The species are very small bivalves, living in similar localities with Cylas, and not uncommon even in drains through meadows. P. pinnaeformis. Shell rounded, oval, not greatly inequi-

lateral, sometimes irregularly striated; valves not swolled, always a little compressed below; umbones usually broad, but little projecting. This is by far the commonest of the smaller Pinctada in this country. It is found abundantly in ponds and ditches. It inhabits generally northern and central Europe.

P. pulchella. Shell small, striated (not grooved); um-

bones simple and without appendages. There are many varieties of this shell. It has a great tendency to assume a shorter side. The left valve is usually about one-third longer, and a line and a quarter broad. It is very common in many parts of Great Britain.

The other British species of this genus are P. Henslow-

sianus, P. striatum, P. cinereum and P. obtusata.

C Y R L A C R E. Cylas, a natural order of Exogenous Plants. The order consists of shrubs with evergreen simple leaves without stipules. The flowers usually in racemes. The calyx 4-5-parted. It has 5 distinct petals, with an imbricated stamnation. The ovary is 2-3-4-celled, always bilocular; the number of carpels different from that of the calyx, corolla, and stamens; solitary pendulous ovules, a short style, the stigmas with as many lobes as there are cells of the ovary. The fruit is a succulent capsule or a drupe; the seeds inverted; the embryo in the axis of a very large quantity of albumen, with a very long superior radicle. This order is related to Oloacanthus and Pituophorus. All the species are inhabitants of North America. Nothing has been recorded of any uses to which they are applied.

C Y T H E R E A, a genus of entomostracous crustacea, belong-

ing to the class Podgyadopoda, the order Ostracoda, and the family Ctenodida. The species are found very commonly in Great Britain. (Brachionopoda.) Mr. Rupert Jones, in his ' Monograph of the Entomostraca of the Cretaceous Forma-

tion of England', describes the five fossil species belonging to this genus. (Entomostraca.) The same author describes ten species of this genus as fossil in the Permian Rocks of England.

C y t h e r e l l a is a genus separated from the group of species known as Cytreas by Mr. R. Jones. It has the following characters:—The animal is unknown. Carapace-valves or shell of an almost regular oblong shape, the dorsal and ventral margins lying nearly parallel to each other. Surface of a very irregular appearance, beaks wrinkled, ridged, and beset with tubercles, and crenulated or strongly toothed on the margins.

Dr. Baird has described three recent species, whilst nine fossil forms have been described by Mr. Jones from the chalk.

C y t h e r i d a is a group of species formerly referred to Cytreas, and separated by M'Coy. The valves externally are convex and smooth, sometimes finely pitted or spinous, never ribbed or granulated; the hinge is simple.

This genus has no recent species. Six species have been found in the chalk.

C y t h e r o t e r i a, a genus separated by Jones from Cytreas. It embraces species of Cytherina of other authors. The cara-

pace valves are oblong, and vary in the convexity and smoothness of the surface; the right valve is larger than the left, and its contact margin thicker than that of the opposite valve. Six fossil species have been described from the chalk.

(Rupert Jones, Monograph of the Entomostraca of the Cretaceous Formations of England; W. King, A Monograph of the Permian Fossils of England, both published by the Palaeontographical Society; Baird, Natural History of the British Entomostraca—Bay Society.)
D

DACRIDIUM, a genus of Gymnospermous Plants belonging to the natural order Fasceae. One of the species, D. farro,
folium, the Kakar Pillar-Tree of New Zealand, acquires a
height of 200 feet. From its branches may be manufactured
a beverage resembling in antiscorbutic qualities the well-
known bek-vine-bark.

DADYR (Cameravy, S. 2.)

DAGUERRE, LOUIS JACQUES MANDE, was born in
1789 at Cormeilles in the department of Seine-et-Oise, France.
At the outset of life he obtained a situation in a government
office, but he early quitted that employment, and became a
peep of M. Dugot, scene-painter at the opera. As a scene-
painter, Daguerre in a few years surpassed his instructor, and
placed himself on a level with the first professors of that
art in Paris, while he quickly extended the capabilities of
the art by various ingenious contrivances, which he invented
for producing increased pictorial effect. He also assisted
M. Prevost in the preparation of his panoramic views of
the great cities of the world. The experience he thus acquired
suggested to M. Daguerre the idea of producing a kind of
exhibition, in which the illusion should be more
perfect than in the panoramas, and he invented, in conjunc-
tion with Bousin, a method of so throwing coloured lights
and shadows upon the view, as to produce the appearance of
changing objects, which he called a daguerreotype.
This they termed a Diorama, and when exhibited, July 1839,
in a circular structure erected for the purpose in Paris, the
success was complete. The diorama in fact made what the
Parisiens term a sensation, and no long time elapsed before
Messrs. Bousin and Daguerre had established a similar building in
London, to which each picture was removed, when it had
been exhibited for its season in Paris. For some seventeen
years picture followed picture, each rivalling its predecessor,
but in 1839 a fire destroyed the building, and the view then
enjoyed the property which sells of precious忙着 of changing
colours, when exposed to the action of the light, and this property
had been the subject of many experiments by scientific men.
Sir Humphry Davy, among recent chemists, had sought by
various applications of this property to obtain copies of
translucent objects, but thoug he succeeded in obtaining
was unable to prevent them from being effaced when exposed to
the light. In France M. Niepce began about 1814 to
pursue a similar course of experiments, and he succeeded in
rendering the images he obtained insensible to the subse-
quent action of the light; but his discovery remained very
incomplete when Daguerre commenced similar experiments.
About 1839 Niepce and Daguerre joined in the prosecution
of their investigations. Niepce died in 1833, before they
had made any decided approach to success. But Daguerre
persevered, and at length his zeal and rare ingenuity met
with an ample reward. He discovered in fact a method by
which he was able to prepare metallic plates, that by
placing them in the darkened chamber of a camera-obscura,
they received a distinct impression of the images thrown upon
them by the lens of the camera, which he was enabled
to reproduce by a subsequent process to render indelible. Some account
of the steps by which he arrived at this grand discovery, the
method adopted for producing, rendering visible, and fixing this
remarkable process of photography, will be found in the article
PHOTOGRAPHY, § 1.] It will be enough to say that with
remarkable patience and ingenuity he surmounted every diffi-
culty, and eventually produced his discovery, as to its prin-
ciples, perfect. Other experimentalists had tried in this ec
sential, and were at work, unknown to Daguerre, at the same
ideas, but to M. Daguerre is due the priority of publication
of the discovery, and no doubt also the priority of discovery,
as far as the producing sun-pictures upon metallic plates is
concerned. What has proved to be the more generally
applicable process of photography, was as unquestionably the
result of the independent investigations of our own country-
man, Mr. Talbot; but, as was to be expected, both the pro-
cesses as now practised are very different from what they were
when originally promulgated by their inventors or discoverers.
Great was the excitement among both learned and un-
learned when in January 1839 M. Daguerre presented to the
Académie des Sciences, an account of the new method
by which, as was said, the sun himself became the artist, and
some of the delineations, with all their wonderful delicacy of
detail, were exhibited. At the same time Daguerre made a
public exhibition of numerous pictures produced by what
he termed the Méthode Niepce perfectiënées.' An exami-
nation of the merits of the new method was, at the sug-
gestion of M. Arago, promptly ordered by the French govern-
ment to be made, and in consequence of the favourable nature
of the report, M. Daguerre was in June 1839 nominated an
Officer of the Legion of Honour; and the project of a law
was on the same day presented to the Chamber—by whom
the law was readily adopted—which accorded to M. Daguerre, on
condition of the full publication of his method, an annuity
for life of 6000 francs, and one of 4000 francs to the represen-
tative of M. Niepce. The rapid extension and improve-
ment of the process of Daguerre (or the Daguerreotype, as it
is now called) was greatly augmented by the free use of the
freely made public property, was due perhaps more to others
than to M. Daguerre, who however never ceased to labour at its
improvement during the remainder of his life. He died
July 13, 1851, at Petit-Bribe-sur-Marne, where a handsome
memorial tablet marks the spot where he retraced by subscription to his memory.

M. Daguerre is the author of two short works—Histoire et
Description des Procédés du Daguerreotype, et du Diorama,'
Savoisie, Paris, 1839; and 'Nouveau Mode de préparer la
Couché Sensible des Plaques destinées à recevoir les Images
Photographiques,' 1840.

(Anno, Rapport à l'Académie des Sciences; A. de Laize,
art. Daguerre in Nouv. Bdeg. Gén.)

DALBERGIA, a genus of Plantae belonging to the natural
order Fasceae, named in honour of Nicholae Dalberg, a
Swedish botanist. It has a campanulatae, 5-calci, 5-st.,
5-pelliculatae corolla, the petals of the keel connected to
the apex; 8-10 stamens, sometimes all monadelphous, with the
tube or shaft chief in front, sometimes divided into two
equal opposite bundles. It has a stipitate membranous
compressed legume, which is flat, oblong, and tapers to
both ends. The seeds, which vary from 1 to 3, are
compressed and remote. The species are sometimes trees, but
tallly climbing shrubs, with inapti-plumulate leaves.

D. monasteri, another of the species, yields a resin very
similar to Dragon's Blood.

There are about 22 species of this genus, none of which are
of any known use except those mentioned.

DALKEITH, Edinburghshire, Scotland, a market-town
and burgh of barony in the parish of Dalkeith, six miles
S.E. from Edinburgh by road, and eight miles by the
Edinburgh and Hawick railway. The population of the
town was 6086 in 1861. The affairs of the burgh are adminis-
tered by 15 trustees. The town stands on an elevated piece
of ground, between the rivers North Esk and South Esk;
consists of one principal thoroughfare, and several small
streets. The town is clean and generally well built; it is
lighted with gas, and well supplied with water. Felt and
beaver hats, straw hats, and woollen stuffs are manufactured,
and there are corn-mills, a brewery, and a tan-work. The
principal market is that of the building of the
Buchanen family. A splendid new church, in the early
English style of architecture, was built in 1840 by
the Duke of Buccleuch. It is cruciform, and has a steeple 167
feet high. An elegant episcopal chapel is situated within
the grounds of Dalkeith palace. The Free Church, United
Presbyterians, and Independents, have places of worship.

In the town are two libraries and a savings bank. Dalkeith park is a large lake of Boiling, surrounded by a splendid park and grounds. The mansion contains many fine paintings. The North Esk and South Esk unite their waters in the park, a little way be-
yond the town, which is situated on an elevated peninsula formed by the two streams. The regality of Dalkeith be-
longed to the Grahams in the reign of David II. It after-
wards passed into the hands of the Earls of Morton, and about two centuries ago was purchased by an ancestor of the present Earl of Rosebery.

Dalkeith after the battle of Preston Pans, and the palace
has been visited by George IV. and Queen Victoria.

DARLIMPLE, JOHN, was born in the year 1804 at
Norwich, where his father was a surgeon in general practice. He graduated in medicine at Edinburgh in 1818, and
in London. He commenced practice as a surgeon in London
in 1827. During the latter part of his career he devoted
himself entirely to ocular surgery. He died in 1852. As
a surgeon-oculist he was better known for his work on the
'Anatomy of the Human Eye,' which was published in 1834.
He was not however known only as a surgeon, but also as
a naturalist and accurate microscopic observer. Amongst
his papers on these subjects the following are the most im-
portant : 'On the Vascular Arrangement of the Capillary
Vessels of the Allantoid and Villitine Membranes in the Incubated Egg.' (A. R. S. Edin. 1834.) 'On the Family of Clos-
tures' (Annals of Science, vol. v.) In 1849 he read a paper before the Royal Society on a hitherto undiscovered infusory animalcule allied to the genus Nodokrassata of Ehrenberg. This paper was interesting as
confirming the discovery of the sexuality of the rotiferous
animalcules, which had been made by Brightwell. This paper
was published in the 'Philosophical Transactions,' and in 1850
Mr. Dalrymple was elected a Fellow of the Royal Society.

DARLING, was one of the surgeons of the Royal
London Ophthalmic Hospital. He was a Fellow of the Roy-
al College of Surgeons of England, and in 1851 was
lected a member of the council of that body.

DAMAGES. The stat. 1 Geo. IV. c. 87, enabling a land-
lord to recover damages in the action of ejectment by which
he recovers possession, although not repeated, is rendered
by provisions to the same effect in the 'Common Law Pro-
cedure Act,' 1852.

DAMAN. [DAMARK.] DANCE, a small natural order of Plants related to the Ferns. They have all the habit of Doraferas Ferns, but their spore-cases are ringless and combined in masses, splitting irregularly by a central cleft. The species are all
found in the following genera:—Korforaria, Anetephoris, Donna, Esophryum, Merytisia, and about fifteen species. Anetephoris erecta is said to be employed in the
Sandwich Islands to perfume cocoa-nut oil. The rhinome of a species of Merytisia is eaten by the Sandwich Islanders.

DANAE. [MINERALOGY, S. 1.] DANUBE. [SARCOUS.] DANEWORTH. [LUTHER.] DAPLEI. [FRENEH.] DAVILLA, a genus of Plants belonging to the natural
order Dilleniaceae. It has 5 very unequal sepals, which
increase after flowering; from 1 to 6 petals, with linear fila-
ments dilated upwards. The single carpel is testaceous, fur-
nished with hairs, and united in the inner concave valvate
sepals. The seeds are solitary, enveloped in an arillus, which
is only open at the apex.

D. elliptica has a shrubby ereth much branched stem, with
hairly branches. The leaves are elliptical, obtuse at each
end, entire, barbicate and leathery, rough and
hairless above, downy and netted beneath; the petiole
vulnus on the under side. The racemes are hairy and bracteolate;

D. ruosa is also a native of the forests of Brazil, and has
a twining stem with hairy twigs. The leaves are oblong,
remotely and obsolete serrate, rough and hairless above, the edges
and principal nerves plicate, and a few petioles to a
very shiny beneath. The peduncles and pedicels hairy, it
has two or three petals. Like the former species it is an
stinging, and is used in South America in swellings of the
legs and different parts of the body.

DE LA BECHE, SIR HENRY THOMAS, an eminest geologist. He was the only son of Colonel Thomas de la
Beche, of Halst Hall, Jamaica, and represented the old family
of De la Beche, who are of ancient origin, and have held
14th centuries. Sir Henry was born near London in 1796.

He went to Jamaica when young, where his father died,
and whilst returning to Europe his mother and her young
son suffered shipwreck. On reaching England they lived a
sufficient time, but Sir Henry, at a very tender age, was
seems to have acquired his first taste for geology. He
was educated at the military school at Great Marlow, which
was afterwards removed to Sandhurst. He entered the army in
1814. In 1817 he became a Fellow of the Geological
Society and in 1821 he was elected a member of the council of
that society, and eventually, in 1847, President.

In 1818 he married. Before this event he had begun to
investigate the geology of Devon, Dorset, and Pembrokshire.
He now travelled on the Continent, and dwelt for some time
in Switzerland. Here in 1820 he produced one of his earliest
scientific papers, 'On the Temperature and Depth of the Laps
of Geneva.' This was first published in the 'Bibliothèque
Universelle,' and afterwards in the 'Edinburgh Philosophical
Magazine.' In 1827 he published a paper on the 'Pleuro-
saurus.' This was done in a paper published in 1823 in the
'Transactions of the Geological Society,' and entitled 'On
the Discovery of a new Fossil Animal, forming a link between
the Ichthyosaurus and Crocodile.'

In 1824 Mr. de la Beche visited his paternal estates in
Jamaica. Here he made himself remarkable for attempting to
introduce ameliorations in the condition of the slave. He
suffered considerably from the Act of Emancipation. Whilst
in Jamaica he was much surprised by the singular information
he received from British amateurs on the subject of science, and a paper published in 1826 in the 'Transactions
of the Geological Society,' on the 'Geology of Jamaica,' was
the result.

Returning to England, his papers on the geology of Dorset,
Devon, and Wales, became very numerous, besides others on the general principles of geological inquiry. Such were his papers on the 'Classification of European Rocks,' 'On the Excavation of Valleys,' 'On the Geographi-
cal Distribution of Organic Remains,' 'On the Formation of
Yew and Gorse, and on the formation of other
others. In 1831 he published his 'Geological Manual,' which
went through several editions, and was translated into French
and German soon after its appearance in England. In this
year he also projected a plan of forming a geological map of
England, and the delineation of the different geological units
should be accurately laid down. He began this gigantic
undertaking on his own responsibility, and commenced a
map of Cornwall. This resulted in the government instituting
the 'Board of Survey and Ordnance.' In 1834 he published
'Researches in Theoretical Geology,' and in 1835, 'How to
Observe: Geology.' In 1845 the Geological Survey and
Museum of Practical Geology were united, and the building
in Jermyn Street, Westminster, erected for the reception of
the rapid increase of the collection of the latter. Sir Henry
succeeded in attracting to this institution a number of ardent
young men of science, amongst whom we may mention the
late Professor E. Forbes, and through their labours this insti-
tution rapidly became one of the most important scientific es-
establishments in the country. In 1851 courses of lectures were
given by the various members of the corps, and under the
name of the Government School of Mines, they are
now on with increasing vigour and usefulness under the presidency of
Sir Frederick Pollock, Sir Roderick Impey Murchison, and Sir Walter
For several years previous to his death, Sir Henry had
suffered from a gradually increasing paralytic disorder, which,
although it prevented him using his limbs, left his fine
intellect almost unimpaired. Day after day it was evident
that his frame became feebler, but his attention to the interests
of the school he had founded did not diminish, and till
DEB
169

DEBENHAM. [Burlon.]

DEBT, ACTION OF. The peculiarities connected with this action, which led to the use in ordinary cases of the action of assumpsit, have for all practical purposes ceased to exist. Wager of law having been abolished, and the pleadings in personal actions greatly simplified, nothing remains to the public mind, and nothing to the courts, of what was so called, from any other action for breach of contract.

DEDINGTON. [Oxfordshire.]

DEEP MOUTH. A term used in the Egyptian and Carian scripts.

DEFAMATION. The jurisdiction of the Ecclesiastical Courts, or, as Blackstone says, of "a petty arrogante in the country" to punish for "railing or contumelious words" in "sacra arma", by means of the "brutum fulmen of ecclesiastical censures," having long been a subject of considerable ridicule, though frequently of grievous oppression to the poor, has at last been abolished by the statute 18 & 19 Vict. c. 41.

DELAROCHE, PAUL, an eminent French painter, was born in Paris in 1797. Early intending to follow art as a profession, he first studied landscape, and was in 1817 an unsuccessful candidate for the Academy prize in landscape-painting. Convinced that landscape-painting was not his vocation, he entered the atelier of Baron Gros, under whose guidance he made rapid progress in the study of the figure. Gros had himself in a great measure thrown off the classic trammels which his master David had fixed on French art, and Delarocque entirely emancipated himself from their thraldom. But he did not desert the study of landscape and architecture, to which his mind had been so much attracted. Still adhering to the old laws, and many of the conventionalities of art. Choosing his subjects to a great extent from modern history, and painting without much regard to academic attitudes and arrangements, he yet sought to maintain the grandeur of style of the ancients and of the Middle Ages. He was, however, with his superiority in his chosen line to be generally recognised, and Delarocque was the acknowledged chief of a school, that school received the name of the "École de Delacroix," in contradistinction to the Romantics of Delaroche and the Classic School of David and his followers.

Paul Delarocque in 1819 and the following years exhibited some paintings of scriptural subjects, but it was not till 1834 that he acknowledged the public. His paintings at that period are noted for the finish of his manner, and the beauty of his composition. His pictures never reach the highest order of art. They are rather melodramatic than epic or tragic. They are suggestive always of a certain kind of stage effect. You see that the painter is aiming at the actor's trick — that he is seeking to make an impression. But allowing for this, it must be granted that M. Delarocque, that estimable countryman of mine, has had undoubted genius, if it was not of the highest order; he was a master of his art; and he was always truthful, conscientious, correct in draughtsmanship, and as a colourist, and tells his story with admirable perspicacity.

M. Delarocque was justly regarded by the French as one of their greatest living painters. His pictures reach the highest order of art. His pictures never reach the highest order of art. DENIZEN. Letters of Deniziation are now disused, aliens generally having recourse to the simpler and more advanta-
geous certificate of naturalization granted by the Secretary of State. [Acres, S. 1.]

DEN'TINE. A genus of Fishes belonging to the Family Spardae. It has the following characters:—Body deep, compressed; dorsal fin, single; head large; teeth conical, placed in a single row, four in the front above and below, elongated, and curved inward, forming hooks; teeth on the branchial arches, but none on the vomer or palatine bones; nose and suborbital space without scales; branchiostegous rays 6. There are several species of this genus.

D. vulgaris, the Four-Toothed Sparus, is regarded as a native of the Mediterranean sea, and seen. It is stated to have been taken in this country, and that by Mr. Donovan in 1805 off Hastings. It is a very common fish in the Medi-
iterranean, and is the Dentex of the Romans. It is remark-
able for the great length of the four anterior teeth in each jaw, which are placed in a single row, leaving a large gap. It weighs from 20 to 30 pounds, and measuring 3 feet in length. Mr. Donovan's specimen weighed 16 pounds. "A more voracious fish," says Mr. Donovan, "is scarcely known; and when we con-
sider its ferocious inclination and the strength of its formi-
dable canines teeth, we may fairly attribute to the great
ability it possesses in attacking other fishes even of superior size, with advantage. It is asserted, that when taken in the fisherman's nets, it will seize upon the other fishes taken with it, and swallow them copiously. This species is
little swiftness, as its teeth are so strong and its gills so
abundant and proximate, and soon attains to a considerable size. Willughby observes that small fishes of this species are rarely taken, and the same circumstance has been mentioned by later writers. During the winter it prefers deep waters, but in the spring or about May it quits this retreat, and approaches the entrance of great rivers, where it deposits its spawn between the crevices of stones and rocks.

"The fisheries for this kind of Sparus are carried on under an extensive charter granted by the Emperor. In the
regions of Dalmatia and the Levant, the capture of this fish is an object of material consideration, both to the inhab-
itants generally as a wholesome and palatable food when fresh, and to the mercantile interests of those countries as an article of export. They prepare it with considerable	
ancient custom, by cutting it in pieces and packing it in bar-
rels with vinegar and spices, in which state it will keep perfectly well for twelve months."

DENTINE. [Tissue, Organic, S. 1.]

DEONARD. Judges and juries having (as stated in the Penny Cyclopaedia, vol. viii. p. 411) alike condemned this species of forficule, the law has been altered by the statute 9 & 10 Vict. c.62, and deodands are now entirely abolished. [Criminal Cases]. The statute 11 & 19 Vict. c. 42, has prescribed with great care and exactitude the mode in which the depositions of witnesses are to be taken in criminal cases. The statute requires a deposition to be put in writing, to be read over to the witness, and to be signed by him. Unless these formalities are complied with, and the deposition has been taken in presence of the accuser, and he has had full opportunity of cross-examination, it is not admissible in evidence against him.

DEPOSITIONS (in Equity). Evidence is now taken in Chancery by an Examinor, and not by written interrogatories, but orally, in the presence of the parties, the witness being subject to cross-examination and re-examination. This new system, in imitation of that put in practice in American courts of common law, which is justly considered a great improvement in fact, was introduced as part of the practice of the Court of Chancery by the statute 15 & 16 Vict. c. 86. (Blackstone's 'Commentaries,' Mr. King's ed., vol. iii. p. 503.)

DEPPING, GEORGE BERNARD, was born at Münster, May 11, 1784. Having completed his educational course, he visited in Paris in 1808, when, forming acquaintance there, and observing the facilities which the city afforded for the pro-
secution of literary studies, he determined to make it his
permanent residence. The rest of his life was spent there in the uneventful career of a busy littérateur.

For many years M. Deppping mainly occupied himself in promoting juvenile and other works chiefly of a geographical subjects, in translating, and in writing for magazines and encyclopedias. His first important original work was one written for a prize offered by the Institute on the 'Expédi-
tion Maritime des Normands en France au Dixième Siècle.' This is a History and Geography of Normandy, written in French, and published in 2 vols. 8vo, Paris, 1830; 'Histoire du Moyen Age, Essai Historique sur leur État Civil, Commercial, et Littéraire,' 8vo, 1840; 'Règlements sur les Arts et Métiers, rédigés au Tréntième Siècle,' and connus sous le nom de Livre des Métiers d'Étienne Boileau,' &c., 4to, 1837; 'Geschichte der deutschen Schifffahrt im Mittelalter,' 4to, 1840; 'La Rénaissance maritime des Normands,' 2 vols. 8vo, Münster, 1840; 'Correspondance Administrative sous le Règne de Louis XIV.' (forming vols. i. to iii. of the 'Collection
Documents Inédits de l'Histoire de France'), 4to, 1850-53; 'Romansco Castellano,' 1 vol. 12mo, Paris, 1817, and several others. M. Deppingle has written also the biographies of various maritime and literary personages, and in some works have been translated into German and Dutch, while seve-
rals of his juvenile works have been translated into most of the European languages. M. Deppping wrote many of the more im-
mportant works of the 'Journal des Sciences,' 'L'Art de diri-
ger les Délices,' &c. He died in Paris September 6, 1853.

DESIGN, SCHOOLS OF. [Science and Art, Depart-
ment of, S. 2.]

DESMENTIA, a group of organised beings regarded by
some naturalists as Animals and by others as Plants. The
terminology who have adopted them into the vegetable kingdom have regarded them as Algae, and allied to the Dicotyledoneae. Some who admit the vegetable characters of Des-
mentia, regard them as classed under the Genus Rhodochry-
seus, and others as under Desmochyseus as a sub-order of the Dicotyledoneae, which he characterises as crystalline branchial fragmentary bodies, brittle, and multiplying by spontaneous separation. Amongst this group of Desmochryseus are classed as being especially peculiar. The following is a list given by Mr. Raffles in his 'British Desmochryseus,' a work which has greatly increased our knowledge of those obscure beings: 'Fresh water figured, mucous, and microscopic Algae, Desmochryseus, Desmentia, and Rhodochryseus, consisting in some genera incompletes. Cells or joints of two sym-
metrical valves, the junction always marked by the division of the endochrome, often also by a constriction. Sporangia formed by the coupling of the cells and union of their con-
tents. It will be seen from this definition that Mr. Raffles regards these beings as plants. The principal points on
which he relies for establishing this position are the occur-
cence of conjugation and swarmmg, and the presence of starch amongst the Desmochryseus."

The union or conjugation of the two filaments for the production of spores, has long been known amongst certain forms of Converre. This has been seen by many observers to occur amongst the Desmochyseus. In the
Eucratium rumputre, p. 3 represents the genera) Nageot describes this process. Two individuals are placed close together, and push out short processes, which meet, and by the absorption of the wall constitute a canal, into which the entire contents of the two cells thus connected enter, and imbibe, so that one becomes a single cell. This process is not always identical in different species. In Closoterium (fig. 6) the middle of the cell-membrane dehiscens with a transverse fissure, and the entire contents from two contiguous opened cells coalesce into a single round or angular mass, and pass into the spore containing green bodies which result from the union of the cells, that they are not in all cases developed into a single Closoterium like spores; but that, as in the case of other Algae, such as
Voschera and Gelodoreum, there are two sorts of spore-
formations, and that under certain circumstances these green bodies represent a germ, capsule, or sporangium, in which, by a process of division, several young Cladostersia come to be produced. The union of the cells of Didemnum Borberi is seen in fig. 1.

The process above described appears to be one entirely confined to the vegetable kingdom, as it has never been observed in unicellular organisms, which are regarded as decidedly animal.

The process of swarming is one which, although a few years ago its distinguishing feature would have been regarded as entailing the organism exhibiting it to a place in the animal kingdom, is now by English naturalists, and is regarded as purely vegetable. It has been observed in many species of Conchocelis, more especially in Cladosteresia and Conchocelis arenosa. The following is M. Agardh's account of this curious phenomenon in the latter plant. After describing the interior matter in the joints, he says—"The granules of which it is composed detach themselves from the mass one after another, and having thus become free they move about in the vacant space of the joint with an extreme rapidity. At the same time the exterior membrane of the joint is observed to swell in one point till it there forms a little mamilla, which is to become the point from which the moving granules finally issue. By the extension of the membrane for the formation of the mamilla, the tender threads of the plant burst between them, making the mamilla at the end of the mamilla, and it is by this passage that the granules escape. At first they issue in a body, but soon those which remain, swimming in a much larger space, have much more difficulty in escaping; and it is only after innumerable knockings (turbations) against the walls of their prison that they succeed in finding an exit. From the first instant of the motion, one observes that the granules or spores are furnished with a little beak, a kind of anterior process always distinguishable from the body of the spore by its paler color. It is on the vibrations of this beak that the motion, as I conceive, depends; at least I have never been able to discover any cilia. However I will not venture to deny the existence of these; for with a very high power of a compound microscope one sees the granules surrounded by a hyaline border, as we find among the ciliated Infusoria on applying a glass of insufficient power. The spores during their motion always present this beak in front of their body, as if it served to show them the way; but when they cease to move, by bending it back along the side of their body, they resume the spherical form; so that before and after the motion one sees no trace of this beak. The motion of the spores before their exit from this point consists principally in quick dartings along the walls of the articular spaces, which themselves are caused by innumerable shocks; and in some cases we are almost forced to believe that it is by this motion of the spores that the mamilla is formed. Escaped from their prison, they continue their course for one or two hours, some hours longer; and retiring gradually towards the darker edge of the vessel, sometimes they prolong their wandering courses, sometimes they remain in the same place, causing their beak to vibrate in rapid circles. Finally they collect in dense masses, containing innumerable grains, and attach themselves to some extraneous body at the bottom or on the surface of the water, where they hasten to develop filaments like those of the mother plant." This process, to which the name swarming has been given, has been observed by Mr. Ralfs, Dr. Halle, and others in various species of Didemum, more especially in Syntrophes crispus and Dragmellum tenuis. No similar movements to these have been anywhere observed among the ova of the animal kingdom.

The presence of starch in the Democclus is a third point relied on by Mr. Ralfs as distinguishing the vegetable kingdom. The existence of this substance is easily ascertained by the well-known reaction of iodine upon it. Meyen first discovered this substance in the Algæ, and Mr. Ralfs and others have since corrected the observation. At the same time it should be stated that starch, although not found present in the tissues of the lower animals, has recently been detected in the brain of man by Mr. Busk ('Microscopical Journal,' vol. ii. p. 106). This may lead to the conclusion that the starch is more commonly met with in the animal kingdom than has been hitherto supposed.

The following reasons are given by Mr. Dalrymple, after giving an account of the structure of Cladostersia, for placing the species of this genus amongst animals—

1st. That while Cladostersia has a circulation of molecules greatly resembling that of plants, it has also a definite organ unknown in the vegetable world, in which the active molecules appear to enjoy an independent motion, and the parietes of which appear capable of contracting upon its contents.

2nd. That the green gelatious body is contained in a membranous envelope, which, while it is elastic, contracts also upon the action of certain reagents, whose effects cannot be considered purely chemical.

3rd. The comparison of the supposed ova with cytoplasm and cells of plants precludes the possibility of our considering them as the latter, while the appearance of a vitelline nucleus, transparent but molecular fluid, a chorion, or shell, determines them as animal ova. It was shown to be impossible that these eggs had been deposited in the empty shell by other Infusoria, or that they were the produce of some Entozoon.

4th. That while it was impossible to determine whether the vague motions of Cladostersia were voluntary or not, yet the idea the author had formed of a suckorial apparatus forbade his classing them with plants.

On these reasons, Mr. Ralfs remarks, that the peculiar organ—the terminal globules—of the Cladostersia are as much vegetable as animal. That the throwing off the contents of the cell through chemical reagents, is as much vegetable as animal. "If fresh water touches Grifithsea oocysts, the joints burst and escape into the current." That the supposed ova contain starch, and are therefore vegetable. That he cannot discover that the orifices at the extremities of some of the Democclus are tubes, or that they possess a suckorial power.

1. Didemnum Borberi, with the cells uniting to form the green matter.

The Democclus are all of an herbaceous green colour, and from this circumstance are easily discovered amongst the other microscopic beings with which they occur. They are mostly inhabitants of fresh water. Mr. Tawte records two or three species from brackish water. They are remarkable for the very definite outline which their forms assume, especially in the genera Microstalasia ('fig. 2'), Enterium ('fig. 8'), Xanthodinum ('fig. 4'), and Pedilastum ('figs. 7, 8'). Their most obvious characteristic however is their evident division into two valves or segments. The point of union between the two segments is in general very definitely marked. In Pedilastum and Smedemus it is less obvious than other genera. It is at this point of union that the cell...
be found in great abundance on the linens, which, if kept moist, will allow of the growth and development of these beautiful objects for many months.

The study of this family will undoubtedly repay the naturalist for years to come. Comparatively little is known of the life beyond the continent of Europe. The following is an analysis of the genera found by Mr. Ralfs in the British Islands:

- Plant an elongated jointed filament. Sporangia orbicular, smooth.
  2. *Delipropogonium*—Filament cylindrical, or sub-cylindrical. Joints with two opposite or dentate projections. (Fig. 1.) Two species.
  3. *Desmidium*—Filament triangular, or quadrangular; joints connected by a thickened border. Two species.
  4. *Aptogonum*—Filament triangular or plain, with formina between the joints. One species.
  5. *Sphaeosoma*—Filament plane, margins incised or sinuated; joints with junction-glands. Two species.

Froend simple from complete transverse division, distinctly constructed at the juncture of the segments, which are seldom longer than broad; sporangia spinous or tuberculated, rarely if ever smooth.

- *Microasterias*—Lobes of the segments incised or bidentate. (Fig. 2.) Thirteen species. Thirty-three genera. Sixteen species.
  6. *Xanthidium*—Segments compressed, entire, and spinous. (Figs. 4 and 5.) Six species.
  7. *Arthrodema*—Segments compressed, and having only two spines or mucros. Two species.
  8. *Staurostomum*—End view angular, radiate, or with elongated processes which are never gynemate. Forty species.
  9. *Delipomeadamum*—Segments angular, each angle having two processes, one inferior and parallel with the similar one of the other segment, the other superior and divergent. One species.

Froend simple, from complete transverse division, generally much elongated, never spinous, frequently not constructed at the centre. Sporangia smooth.

- *Tetramorium*—Froend straight, constructed at the centre, and notched at the ends. Three species.
- *Penium*—Froend straight, scarcely constructed at the centre. Eight species.
- *Dioecium*—Froend straight, much elongated, constructed at the centre, truncate at the ends. Seven species.
- *Clorostomum*—Froend crescent-shaped or aruncate, not constructed at the centre. (Fig. 6.) Twenty-two species.
- *Sporoziella*—Froend straight, not constructed at the centre; endochromie spirally twisted. Two species.

- *Cells elongated, entire, fasciculated.*
- *Anhydremma*—Cells aggregated into faggot-like bundles. (Fig. 3.) One species. *Sporangia unknown.*

Froend composed of few cells, definite in number, and not forming a filament. (Fig. 7 & 8.) Eleven species.

- *Podostrium*—Cells arranged in the form of a flattened star, their outer margin bidentate. (Figs. 7 & 8.) Eleven species.

- *Bacillaria*—Cells oblong or fusiform, entire, placed side by side in a single row, but during division into two rows. Six species. (Ralfs and Jenner, *British Desmidiaceae: Siebold, On Unicalcal Plants and Animals, in Misc. Journal, 1855; Meneghini, On the Animal Natural History Described, translated by Ray Society, 1854; A. Braun, On Rejuiemence in the Plant, translated by Ray Society, 1854; Lindley, "Vegetable Kingdom; Nügeli, Gattungen einzelliger Algen physiologisch und rassbachisch, Zürich, 1840; Cohn, On the Natural History of Protococcus platensis, translated by Ray Society, 1864.*
DETRINE. In this action the defendant could, until recently, in all cases retain the chattels which the plaintiff sought to recover, on payment of the damages awarded by the jury as the alternative of not giving them up to the owner. If the plaintiff, therefore, was desirous of recovering the very chattel itself, he was obliged to seek relief in a court of equity, which, on the palpable ground of being insufficient, interfered, and compelled the defendant to make a specific delivery to the plaintiff of his property. It is no longer necessary to resort to the Court of Chancery for the specific deliverance of chattels. Courts of Equity now have the same powers as the Court of Equity to enforce the specific delivery of the chattels recovered in the action of detinue. ('Common Law Procedure Act,' 1864.)

DEXTRIN. [CHEMISTRY, § 1; TISSUES, ORGANIC, § 1.]

DIANE/A. [FULMUNDAEA.]

DIASPOR. [MINERALOGY, § 1.]

DIASTASE. [CHEMISTRY, § 1.]

DIATOMACEE, or DIATOMITE, a group of organised beings which naturalists have placed in the animal vegetable kingdom, according to as they have regarded their structures as most allied to the one kingdom or the other. These organisms consist of a single cell, and are remarkable for possessing a siliceous pellicle or frustule, which is composed of silice or flint, and which remains permanent after its organic tissues have perished.

The following is a definition of this group of beings by one of the most recent writers on this subject:—Plant a frustule; construct a cell or a vessel with the aid of a bivalve siliceous epidermis. Geminaries increase, by self-division; during which process the cell secretes a more or less siliceous connecting membrane. Reproduction, by conjugation, and the formation of sporangia. (W. Smith.)

The Diatoms are endowed with the power of motion; and when this function was supposed to be peculiar to the animal kingdom, it is not to be wondered at that the first observers of these organisms referred them to the animal kingdom. Ehrenberg, in his work on 'Infruticous Animals,' says: 'We add to our knowledge of this family, and added to the forms that were already known. He regarded them, as well as the Demidie, and other beings which are now generally referred to the vegetable kingdom, as animals. The following are the principal points on which he relied for assigning to this position:—

1st. The Diatomacee exhibit a peculiar spontaneous movement, which is produced by certain locomotive organs.

2nd. A large number of them have in the middle of the interior of their cells a large round or oval nucleus, situated, which became coloured blue when placed in water containing indigo, just as many of the Polygastrics Infusoria. (fig. 19.)

3rd. The shells of the Diatomacee resemble in structure and conformation those which are seen in the Mollusca and other animals.

These arguments are met on the other side by the statement, that spontaneous movement is now known not to be specially animal, as the spores of many Algae, and their entire fronds are known to be actively motile. In the next place the colouring of the interior by indigo also takes place in truly vegetable structures.

The complex structure of the minute siliceous frustules of the Diatomacee is a fact that has struck many observers. Certainly it is without a parallel in the vegetable kingdom. Schleiden in his 'Principles of Scientific Botany,' after giving a minute analysis of the siliceous structure of Navicula viridis (fig. 6) represents this genus, says: 'Such an artificial and complex structure, and one that has no parallel, is entirely without significance. In all true plants we find the silica present in a very different form, as minute scales or drops, and distributed through the substance of the cell-wall. Again, in another place he says, 'This curious structure is wholly without a parallel in the vegetable kingdom, and cannot be derived from the laws of vegetation with which we are at present acquainted.'

More recently Professor Meneghini has come forward as an advocate of the animal nature of the Diatomacee. In a very lucid and remarkable essay, published at Venice in 1845, he says:—

'We must suppose them to be plants, we must admit every frustule, every navicula, to be a cell. We must suppose this cell with walls penetrated, a cell that has developed within another cell of a different form, at least in every case where there is an obvious peduncle or investing tube. In this silicious wall we must recognize a complication certainly unsealed in the vegetable kingdom. If we were still remain in the eminently nitrogenous internal substance corresponded with the gomitic substance, and that the oil-globules could take the place of starch. The multiplication would be a simple cellular deduplication (odopliantum), but it would remain to be proved that the two distinct primitive unicells or by the introduction or constriction of the wall itself. Finally, there would still remain unexplained how the frustules, not only vegetable, but even the probable ternary non-axillar composition of the external gelatinous substance of the peduncles and investing-tubes. But as the presence of nitrogen is not a positive character of animal nature, so the absence of it is not a proof of vegetable. And in order that the objection should really have some weight, it would be well to demonstrate that this substance is isomeric with starch. For then, supposing all the arguments in favour of the animal nature of the Diatomacee were proved by such a number of most circumstantial observations, this peculiarity, if it deserveth the name, will be regarded as an important discovery. We should then have in the animal as well as in the vegetable kingdom a ternary substance similar to that forming the basis of the vegetable tissue in the Dictyoneurum.'

Of the chemical composition of the Diatomacee little satisfactory has at present been made out. Professor Frankland of Manchester, according to the Rev. W. Smith, whose work on the British Diatomacee is one of the last that has hitherto been published, has found that a large amount of iron exists in the state of a silicate or protosilicate in the silicious frustules, which probably accounts for the brown or yellow colour of these organisms. On the application of external means to the shells, the shells become broken and their contents, and converts these from a golden-yellow to a bright green. On the addition of sulphuric acid they exhibit a deep brown hue.

The fact which is most relied on to support the vegetable nature of the Diatomacee, by those who advocate this view, does not appear to have been known to Meneghini, and that is the conjugation of the cells of which they are composed in the same manner as in the Dictyoneuro. [DEMIDIE, § 2.] This discovery was made by Mr. Tawseiles, and observed in the species of Eunana (fig. 19.), Fragilariopsis, and other species. This process takes place as follows:—Two individuals closely approximated deliquesce in the middle of their long diameter, whereby one of the individuals arises in one situation, and the opposite frustule. These indicate the future channels by which the endochron of the two frustules becomes united, as well as the spot where subsequently the double sporangium is developed (figs. 8, 19). From the sporangium the new individuals are developed. This process is precisely analogous to what takes place in the Dictyoneuro, so that the frustules of the Diatom must be regarded as cells of the same individual. "If we duly consider this," says Mr. Tawseiles, "which does it the lower tribes of plants in our estimation! since we may contemplate an individual plant of them not as the single phytos—not as the single frond—not as the single cell— but it may be as the aggregate thousands of these;—view it occupying as much space, and forming as much surface in the economy of nature as the largest forest-tree!"

The mode by which the cells are multiplied amongst the Diatomacee appears to be strictly in accordance with what occurs generally in the vegetable kingdom. This process is one of self-division. The first step is the fragment or division of the internal cell, "probably by the doubling-in of its membranous wall, and consequently the separation of the endochron, or cell-contents; the central vesicle or cytoplasm also dividing into two parts, which adhere to each other; these movements being simultaneous with a retrocession of the epidermal valves and the formation of the silicious connecting-membrane already described. In the centre of the enlarged frustule, in exact opposition to the original valves and closely applied to each other; these valves, covering the surface of the cell-membranes along the line of fission. The divided portions of the endochron
spread themselves along the membrane which is embraced by the new valves, and there result two half-new frustules bound together by the connecting membrane, generated during the process we have described.

"During the healthy life of the Diatom the process of self-division is being continually repeated; the two half-new frustules at once proceed to divide again each into two frustules, and thus the process continues. I have been unable to ascertain the time occupied in a single act of self-division, but supposing it to be completed in twenty-four hours, we should have, as the progeny of a single frustule, the amazing number of one thousand millions in a single month; a circumstance which will in some degree explain the sudden or at least rapid appearance of vast numbers of these organisms in localities where they were but a short time previously either unrecognized or only sparsely diffused." (Smith, p. 266.)

become solid except by crystallizing or depositing itself on some pre-existing substance. On the other hand, we cannot admit, with Nigelli, that it has been deposited externally for in many genera, and especially in the 

"Achaeanthids, the siliceous shield is covered with a very delicate, distal membrane, itself containing silica, as is proved by the observation of several authors on the action of silica and acids. Therefore, comparing this shield with other organic formations whether animal or vegetable, containing in like manner either silica or some other so-called mineral element, we may reasonably assume that the whole is cemented or intimated by silica. This permeation may occur either in the wall of a simple cell, as is seen in the epidermal cells of many plants, or within minute cells, as in various plants and animals. The action of heat or of acid, in these cases, destroys or dissolves the matter and leaves the silica untouched; does not alter the apparent form of the organ, because the skeleton remains unaltered.

"Externally to the shield 

Nigelli observed a thin stratum which is denominated cement, which may be made visible either by desiccation or by calcination; and produces either a simple opacity, or lines, points, and maculae, sometimes irregularly disposed, sometimes regularly. He supposes it to be a silicate of iron or of alumina. Independently of the chemical materials which it may contain, this outermost "cement" seems to me the more important, inasmuch as even without resorting to the means indicated by Nigelli, I observe it to be constant, not merely in the species enumerated by him, but also in many others, and I could almost assert that it occurs in all. For to me it appears to appertain with that fine membrane of the 

Achaeanthids above mentioned, which, according to Kützing's own observations, is always visible whenever the two new individuals (in duos) that 

Diatom is resolved in its multiplication by d 

duplication (duplicationis) begins from points and lines supposed to belong to the subjacent shield very frequently to this kind of covering.

The shield itself is formed of at least four pieces, or valves, united together in a four-sided figure—a tetragon. The mode of union is unknown. But the existence of a kind of articulation which permits an opening and closing, like the valves of a shell-fish described by Corda in a species of 

Surirella, has been denied by other observers. Be this as it may, whether spontaneous after death or induced by external means, this separation does take place in a regular manner. Now, if we suppose an organic cell with a wall permeated by silica, and with a four-sided figure, we can easily suppose that all the sides will mechanically support each other. Moreover, we shall meet with numerous examples of a different kind of analogy, namely, that with solid animal tissues belonging either to the internal skeleton or the external tegument.

The four valves are equal in length, but in many species and genera one pair exceeds the opposite pair in breadth. In order to establish an uniform language it is convenient to term these primary valves or surfaces which exhibit along the middle the line of division in the act of deduplication, which, since it is formed here in a normal manner, is parallel to the other two surfaces, denominated lateral. Along the primary surfaces we frequently see longitudinal lines, which terminate at the two extremities in small apertures. From their internal surface there project into the cavity linear marks variously formed but always longitudinal; these are termed vitre.

The lateral surfaces have frequently a rounded aperture of greater or smaller size in the centre, and from this a fissure extends outwards, sometimes only on one side, and sometimes itself gradually or expands into the regular terminal apertures. When this occurs each of these surfaces is divided into two distinct valves. On these lateral surfaces we observe the striae, longitudinal and transverse costae, no less admirable for their beautiful linear appearance than for their constant regularity in number, direction, and proportion. When many individuals are united together to form one compound being, like a polypl, for instance, it is always by the lateral surfaces that they unite; and since all other characters sometimes fail, we can affix to them the denomination 'lateral' from this principal one.

Besides the vitre before mentioned, in some general (Busk, fig. 15, Clathraaphos, Terpinoe) there are other solid ridges in their internal cavities; these are variously arranged.

These essential peculiarities of the shield may perhaps
be regarded as indicating a complex structure, very different therefore from what would be prescribed by a simple cellular wall. Ehrenberg deduces from its an arrangement to compare it with the shell of *Mollusca*. The *Aviculoidea* may be cited among the *Alveolaria*. Kölliker, in reply, that among vegetable cells there is found a peculiar conformation of the walls, with prominences, depressions, points, lines, papillae, and perforations, disposed in a regular manner; he refers to grains of pollen, as an instance. He might have added the more appropriate instance of the *Diatoma*, which could be very closely allied to the *Diatomae*, if the latter, like the former, could be referred to the vegetable kingdom. If not equal in constancy and regularity, the *Diatomae* display a greater degree of uniformity than the *Aviculoidea*, owing to the different nature of their substance, for in the vegetable cell, when lime or silica predominates, the wall becomes uniform and regular (l'unicorne ed irregolare)."

The siliceous epidermis presents an extraordinary variety of forms, which in every genus and species offer the best possible means of distinction and identification: striæ, or lines frequently moniliform, dots arranged in a radiate or concentric manner, and minute divisions presenting perfectly hexagonal outlines, are amongst the most frequent ocurrences. It has been said with justice that the examination of the nature of these. Mr. Smith says, "I am disposed to regard them all as modifications in the arrangements of the silex of the valve, arising from the mode of development peculiar in each, to the tubes which within are more or less "cristated." He also denies that there are any perforations in the valve, as supposed by Ehrenberg and Kölliker. These foramina are also denied by Schleiden. Mr. Smith denies also that the valves are externally covered with any organic membranes.

The delicacy of the markings on many of the *Diatomacea* render them objects peculiarly adapted for testing the powers of the object-glasses of the microscope. The following table, drawn up by Messrs. Solliet and Harrison of Hull, to whom microscopy is indebted for having first pointed out the nature of these objects, is presented by them at the meeting of the British Association at Hull in 1853:

The *Diatomaceae* possess the power of moving. "The cells have no special organs for these movements. But as, in consequence of their nutritive processes they take in and give out fluid matters, the cells necessarily move when the attraction and the emission of the fluids is unequally distributed on parts of the surface, and is so active as to overcome the resistance of the water. This motion consequently is observed more particularly in those cells which, in consequence of their taper forms, easily pass through the water; these cells moreover move only in the direction of their long axis. If one half of a spindle-shaped or elliptical cell chiefy or exclusively admits material, the other half, on the contrary, giving it out, the cell moves towards the side where the admission takes place. But, as in these cells both halves are physiologically and morphologically exactly alike, so it is that it is first the one and then the other half which admits or emits, and consequently the cell moves sometimes in one, and sometimes in the other half of its thinness." (W. Smith.)

This is perhaps as satisfactory an explanation of these movements as can be given in the present state of our knowledge. All observers agree that they can find no evidence to support Ehrenberg's account of a pedal or ostiate organ projected from the interior of the siliceous shield. The Rev. W. Smith has also detected cyclosis in the *Diatomaceae*. "A distinct movement," he says, "of the granular particles of the endochrome, closely resembling the circulation of the cell-contents in *Chara trichiata*, noted by Mr. Ralfs [Demidoff], and which I have frequently detected in the same species, has occasionally fallen under my notice in some of the larger forms of *Diatomaceae*. He has observed it in *Surirella hysterae.* This publication, after young did not, however, the regularity of movement so conspicuous in the *Demidoff*, and is of too ambiguous a character to furnish data for any very certain conclusions, save one, namely, that the *Diatom* must be a single cell, and that the repeated contents of separate organs, such as have been alleged to occupy its interior; since the endochrome moves freely from one portion of the frustule to another, approaching and receding from the central nucleus, unimpeded by any partition."

The *Diatomaceae* are the most abundant and extensively distributed of unicellular organisms. They are found in the ocean, at the mouths of rivers, in brackish waters, in rivers, lakes, ponds, ditches, pools, and estuaries. In fact, wherever a few drops of water are allowed to remain exposed to the air, we may expect to find forms of *Diatomaceae*. Their forms are not less abundant than their presence. In the first volume of his "Synopsis of the British Diatomaceae," the Rev. W. Smith has described upwards of 380 species, and the number of new species of *Diatomaceae* of British species known in Great Britain is considerably above 800. The facility with which their forms are preserved, give to these objects a great advantage, and a handful of sand from the sea or from any river in the most remote district of the world may be expected to reveal a number of the abundant forms. They occur in great abundance in the river Thames, and its mud affords a large variety of the frustules of those which have ceased to exist. In a recent report on the Microscopic Examination of the Condition of Muddy Rivers, and other Water," by Dr. Lankaster and Rodem, upwards of forty species were observed.

The mode of collecting living specimens for observation is simply to allow the water in which they exist to stand fast for a few hours, when, by carefully draining the water, the portion remains at the bottom of the vessel more turbid than the rest, and which generally contains in large numbers the objects sought for.

In describing the bowers of coloured dust which have occurred in various parts of the world, Ehrenberg has demonstrated that various forms of *Diatomaceae* have been found present. In some seasons these organisms occur in such numbers in the waters of rivers as to give to their banks a peculiar physical aspect. In the autumn of 1841 the stones and pebbles in the nearly dried-up bed of the Annan, in Dumfrieshire, presented an appearance as though they were white-washed. The substance which gave the stones this appearance could be scraped off, and looked like some form of calcareous matter. On further examination, however, Dr. Lankaster found that it consisted entirely of the siliceous shields of a species of *Synedra*. (Fig. 5.) In the first volume of the new series of the "Transactions of the Microscopical Society," Mr. Shadbolt has given an account of the examination of portions of mud given him by Mr. Dusk from Port Natal. This mud was recent, and from the nature of the specimens in it, Mr. Shadbolt thinks it probable that it was obtained not far from the mouth of some river. In this mud he made out fifty-five distinct species of *Diatomaceae*, twenty of which he has described as entirely new species. In the "Microscopical Journal" for July, 1853, Mr. Brightwell of Norwich has described nine new species of one genus—*Surirella*—and a number of new species are being detected nearly all the recent species described in this memoir in material obtained from the surface of the large sea-shells of the genera *Hipposoma* and *Haliaeita* before they have been cleaned. Many of them in this state are covered with small zoophytes, minute algae, and other minute organisms; thus presented to the naturalist are entirely new, and are amongst the most singular of the family. It has been suggested that the silex thus introduced into the guano may contribute to its fertility, as it is well known that this sub-
The polishing powder or slate (polischief) found at Bilu in Bohema is used for the purpose of producing a polish or fine surfaces. This irregularity of the frustules of the Diatomae well adapt them to this purpose.

Another deposit in which the Diatomaceae have been found in great abundance is the Bergmeilh of Sweden (Bemsha, 5. 1.). The Diatomae found by Ehrenberg in this formation are principally species of Navicula. (Fig. 6.)

Amongst the tertiary deposits, beds of Diatomaceae are very common. They have been observed in Italy, in Germany, and in several of the States of America. The city of Richmond in Virginia is said to be built upon a stratum of Diatomaceous remains, 18 feet in thickness. (Smith, Professor Gregory of Edinburgh has recently described, in the 'Transactions of the Microscopical Society,' a Diatomaceous earth, discovered about two years ago by the Duke of Argyll in the Isle of Mull. It constitutes a soft bed, resembling marl in appearance, lying in a rough piece of ground between Loch Baas and the sea. The lake is about 30 feet, the land about 40 feet, above the sea-level. At one part there is a hollow, which in winter used to become a small loch, in summer only a stagnant pool, and in draining this the bed of marl was discovered. The bed rests upon gravel, which appears to belong to the diluvial period, and the Diatomaceous earth is probably of recent origin. Professor Gregory has sent a sample to the directors of the British Geological Survey, and has given a list of upwards of 130 species, which he has been able to make out (Quarterly Microscopical Journal, January, 1854). Of these upwards of twenty are altogether new species, or species that are new in a British locality. From these facts it will be seen that the subject of fossil Diatomaceae promises an almost boundless field for further inquiry. It appears that we may say of these organisms what we can say of no other family or group of organised beings, that once created they exist for ever. Myriads of species of soft-bodied animals have perished, never to be recognised, but each individual cell of the Diatom leaves its silicious wall as a record of its existence—a record that the ordinary forces of nature seem to have little or no power in obliterating.

We now turn to the subject of arrangement. It would of course be impossible here to give any account of individual species, and systematic arrangements are being constantly modified by new discoveries. The following is an arrangement of the families or tribes by Kitting:

Tribe I. STRIATA.

Order I. ASTRONAUTICA.

Without a central opening on the secondary valve.

- Transverse striae unbroken.

Family 1. Euonoe.
Family 3. Pogonaria.

** Stria broken (interrupted) in the median line.

Family 5. Survitellas.

Order II. SISTOMATIC.

With the central opening.

- Monostomatic.

Having a median aperture on only one of the secondary surfaces.

Family 6. Cocconeis.
Family 7. Achmea.

- Diatomica.

With a median aperture on each secondary surface.

Family 8. Cymbelina.
Family 9. Geitlerin.
Family 10. Navicula.

Tribe II. VITTATA.

Order I. ASTRONAUTICA.

Without central opening on secondary side.

Family 11. Licmophora.
Family 12. Striatelles.
Order II. Stemataceae.

With a large distinct aperture.

Family 13. Tabulariaceae.

Sub-Tribe 1. Connecting membrane subperisent as a siliceous annulus; frustules after self-division united into a cylindrical filament.

3 Genera—

1. Tabellaria... 2 species.

2. Amphipteris... 1 species.

3. Biddulphia (fig. 15)... 4 species.

1. Iaithia... 2 species.

Sub-Tribe 2. Membrane subperisent; frustules after self-division united into a anatomous enclosure.

3 Genera—

1. Podoloria... 2 species.

2. Melolipus (fig. 16)... 6 species.

3. Orthoria... 6 species.

Sub-Tribe 3. Frustules invested with a gelatinous or membranaceous envelope.

1. Family 17. Dictyodonteae.

Family 18. Anciaceae.

Family 19. Actiaceae.

The Rev. W. Smith, in his 'Synopsis of the British Diatomceae,' gives the following arrangement of the genera:

Tribe I. Frustules naked; not imbedded in gelatinous nor inclosed in membranaceous tubes.

Sub-Tribe 1. Connecting membrane deciduous; frustules solitary, or during self-division in pairs; rarely in greater numbers, adherent or free, dispersed, or aggregated into a mucous stratum.

22 Genera—

1. Epiactis (fig. 19)... 16 species.

2. Exarata (fig. 1)... 7 species.

3. Cymbella... 6 species.

4. Amphora... 8 species.

5. Cocconeis... 6 species.

6. Coecinodiscus... 3 species.

7. Euxipho (fig. 2)... 6 species.

8. Actinocyclus... 1 species.

9. Arachnoides... 1 species.

10. Tetracrinum (fig. 3)... 4 species.

11. Cyclotella... 4 species.

12. Campylodiscus... 7 species.

13. Sardinella (fig. 4)... 20 species.

14. Trybliionella... 6 species.

15. Gymnocalveolus... 6 species.

16. Nitzschia... 23 species.

17. Amphiporella... 5 species.

18. Amphipora... 2 species.

19. Navicula (fig. 6)... 36 species.

20. Pinnularia... 24 species.

21. Staurotesta... 10 species.

22. Pleurosigma (fig. 7)... 25 species.

Sub-Tribe 2. Connecting membrane subperisent; frustules after self-division attached by a gelatinous cushion, or dichotomous striæ.

7 Genera—

1. Synedra (fig. 5)... 24 species.

2. Daphora... 2 species.

3. Cocconema (fig. 6)... 4 species.

4. Dicranoma (fig. 9)... 12 species.

5. Podaphora... 5 species.

6. Haplophora... 2 species.

7. Loxophora... 2 species.

Sub-Tribe 3. Connecting membrane evanescent, or obsolete; frustules after self-division united into a compressed filament.

15 Genera—

1. Morsella (fig. 10)... 2 species.

2. Bacillaria (fig. 11)... 1 species.

3. Hinnaitestia... 7 species.

4. Odontidium... 4 species.

5. Denticula... 4 species.

6. Fuwaria... 3 species.

7. Encostoma... 1 species.

8. Achnanthes (fig. 9)... 6 species.

9. Diademia... 3 species.

10. Rhabdomor... 2 species.

11. Sertularia (fig. 12)... 1 species.

12. Tetracyclus... 1 species.

Sub-Tribe 4. Connecting membrane subperisent; frustules after self-division united into a zigzag chain.

6 Genera—

1. Diatoma (fig. 14)... 4 species.

2. Grammatophora... 2 species.

3. Tubellaria... 2 species.

4. Amphipteris... 1 species.

5. Biddulphia (fig. 15)... 4 species.

6. Iaithia... 2 species.

Sub-Tribe 5. Connecting membrane subperisent as a siliceous annulus; frustules after self-division united into a cylindrical filament.

3 Genera—

1. Podoloria... 2 species.

2. Melolipus (fig. 16)... 6 species.

3. Orthoria... 6 species.

Sub-Tribe 6. Frustule indefinite; mammillate; frustules scattered.

1. Mastogloia... 3 species.

Sub-Tribe 7. Frustule definite; compressed or globular; frustules scattered.

2 Genera—

1. Dickoria (fig. 17)... 3 species.

2. Berkleopora... 1 species.

Sub-Tribe 8. Frustule definite; filamentous; frustules in rows.

3 Genera—

1. Encosoma...

2. Colleoma...

3. Schizosoma (fig. 18)... 16 species.

Sub-Tribe 9. Frustule definite, filamentous; frustules fasciulated.

1. Homoeocladia... 3 species.

DIBDIN, REV. THOMAS FROGNALL, the most conspicuous English writer on Bibliography in the earlier half of the nineteenth century, was born at Calcutta in 1776. His father, Captain Thomas Dibdin, the commander of a sloop of war in the Indian Ocean, was the elder brother of Charles Dibdin, the celebrated naval song-writer. [Jems, Caxton.] Both he and his wife, whom he had first met in the East Indies, died on their passage home in the year 1780, and Froggall Dibdin first landed on the English shore an orphan of four years old. His mother's brother, Mr. Compton, took charge of him from that age to man's estate; and of other relations he saw so little, that, he tells us in his 'Reminiscences,' he conversed with his famous uncle Charles but once in his life, though Charles lived till 1814, when Frognall was eight-and-three, and was sent to St. John's College, Oxford, but quitted the university without taking a degree, and studied the law under Mr. Basil Montagu, whose office he left to practise in the unusual character of a provincial counsel at Worcester.

Finding no prospect of success, he soon abandoned the law for the church; and a passage in his 'Reminiscences,' in which he describes his studies, furnishes the key-note of much of his subsequent career. "In Greek Testaments my little library was rather richly stored. I revelled in choice copies of the first Erasmian, and of the first Stephanus, and defied any neighbouring clergyman to match me in Elzevirs and in Tossorin." In London, to which he speedily returned, and where he became a preacher at some fashionable chapels at the west-end, he was less known in the clerical than in the literary or rather the bookselling world. At that time, the "bibliomania," as it was called, or fancy for purchasing rare 2 A
and curious books at extravagant prices, was advancing to a height which it had never before attained in England or elsewhere. It reached its culminating point at the celebrated sale of the library of the Duke of Roxburghe, in June 1812, where a copy of an early edition of Boccaccio, printed by Vrba in Venice in 1471, was bought by Mr. B. R. Haldorn, afterwards Duke of Marlborough, for the sum of £260; and it was afterwards discovered that an imperfect copy of the same book was in the Sunderland library at Blenheim, at the very time of the purchase, but had three times the price placed upon it. This was mentioned in the Notice.

Dr. Dibdin proposed, at a dinner party at Baron Bolland's, even before the Valaderf was sold, the establishment of a club, to dine together in honour of Bibliography. The club was formed on 17th May, 1817, and was named the Roxburghe Club, and he became the first vice-president. This club afterwards adopted the rule that each of its members should yearly reprint a book, to be presented to every member; and this practice seems to have led to the establishment of the numerous printing and publishing clubs now in existence, more liberal in their regulations than the original. The rise and progress of the bibliomaniac was stimulated and recorded by different publications of Dr. Dibdin: an Introduction to the Greek and Roman Classics, in 1802; a dialogue, entitled the 'Young Man's Guide to the Laos of France and Germany,' in 2 vols., 1811; and the Bibliographical Decameron, in 3 large vols., in 1817. A new edition of Aesop's 'Typographical Antiquities' was also commenced by him, but was not completed until 1819; and a minute account of the rare books in Earl Spencer's library, under the title of 'The Bibliotheca Spenceriana,' which occupied four volumes, and was extended by the 'Archive Althorpiana,' a description of Earl Spencer's seat at Althorp, in Northampton; or, 'Young Man's Guide to the Old Man's Commonplace in the Choice of a Library' (1824), he apparently appreciated at producing something of more general and permanent use; but the result was disastrous. The flippant and frivolous character of his remarks, and the inaccurate and superficial character of his information, were resented upon in so severe a tone by some of the leading reviews, in particular the 'Quarterly' and the 'Westminster,' that his reputation never recovered the shock. In the preceding year he had obtained the post of Earl Spencer's librarian, and was introduced to the church—the living of Exning, near Newmarket; he was afterwards appointed to the rectory of St. Mary, Bryanston Square, London; and his publications for some years were chiefly of a theological character. He returned to the field of literature with his Reminiscences of a Bibliomaniac (2 vols., 1830), and in his Bibliographical, Antiquarian, and Picturesque Tour in the Northern Counties of England and in Scotland (3 vols. 1838). He also made, not long before his death, a tour in Belgium, of which he also intended to publish an account. He died on the 18th of November 1847, after a long illness, of paralysis of the brain. His latter years had been much clouded with pecuniary difficulties.

Many of the publications of Dr. Dibdin have already been enumerated, but it will be necessary to recur to some of them to afford a fuller notion of their character. The most important is the 'Typographical Antiquities of Great Britain.' The meritorious work of Amos Dibdin, the subject, professing to give an account of all the books printed in England from the introduction of the art to the year 1600, had been expanded from one volume to three by Herbert, who made such extensive additions that the work might justly be regarded as a new one. But little room for extensive improvement on Herbert—a very great alteration even in the arrangement would have much increased its value to nearly all who consulted it. The titles of the books are given in two ways, first under the name of the printer, and then under the name of the publishers: had they been disposed instead, according to the plan adopted for the 'Annals of German Literature,' in the plain order of date, a host of particulars would have presented themselves in combination which are now scattered and inaccessible. It would have been far from uninteresting to observe what books issued from the press in England during the year in which Henry broke up the monasteries, in which Mary lighted the fires of Smithfield, or in which Shakespeare first came to London. Dibdin has preserved the old arrangement, but has made the Mendelssohnian mistake of giving the marginal numbers of his edition, which was left imperfect, carry the record no further than the middle of the second volume of Herbert's three. Some of the matter which he has added is of interest, in particular his more minute account of the productions of the presses, but it is crowded and more or less common to book-collectors of the 18th century, illustrated with their portraits, which have nothing whatever to do with the history of printing in the 16th and 17th centuries. Much too of the character of the 'Decameron' is preserved in the 'Reminiscences' from the manuscript notes which Herbert had prepared for a second edition, and inserted in a copy of his work which is now in the British Museum. It is to be hoped that the whole subject will be resumed ere long by some competent scholar, with the numerous additional materials which he has command in our public libraries, when, with some industry and intelligence, a work may be produced which will interest not only the bibliographer but all who have a tincture of feeling for literary matters. The 'Bibliotheca Spenceriana,' from the first to the last, isprodigious, with little to do to the public in general, is often used as a work of reference: but those who have consulted it the oftener regard it with the most distrust. Such was Dr. Dibdin's habit of inaccuracy, that he is not at all unlikely to have regarded the English nobility of the name of 'Decameron' as 'the English version of the Decameron,' and to have given the story of the date of the latter as being 'on the evening before the sale of the Boccaccio of 1471, which took place on the 17th of June, 1512.' It may easily be conceived that his accounts of the dates of rare books are not to be depended on till after they have been verified. It may be remarked also, that the object of describing a book has too little of the scholar and the man of letters, and too much of the bookseller and the bookbinder. The width of the margin, and the kind of leather in which a book is bound, attract as much of his attention as the matter of the book; which all copies of the book have in common. The 'Decameron' are a singular compound of anecdotes of rare interest mixed up with the most idle and irrelevant matter. The 'Decameron' is by far the best of Dr. Dibdin's works, as comprising the least of the detail and the most of the anecdote; and it is often in many portions with a degree of care and spirit often wanting in his other works. The 'Reminiscences' afford singular proof of that, although the author of an 'Introduction to the History of Printing' in England, first of its kind, and more than usually deficient. On the whole, though his bibliographical works abound with much that the reader wishes away, they are indispensable in any large library of English literature. His other productions, which are numerous, are mentioned in the 'Reminiscences.'

DICHROITE. [MINERALOGY. S. 1.]

DICK, THOMAS, LL.D., was born in 1772. He was educated for the Christian ministry in connection with the Secession Church of Scotland, and was a preacher in connection with that body in the early part of his career, but it is as a popular writer on physical science that he is best known to the world. The works by which he first became generally known were the 'Christian Philosophy,' which followed by works on the 'Improvement of Society by the Diffusion of Knowledge,' the 'Mental Illumination of Man,' 'The Philosophy of a Future State,' a 'Treatise on the Solar System,' 'Celestial Scenery,' 'The Sidereal Heavens,' 'The Practice As Well as the Theory of Christian Beneficence, contrasted with Covetousness,' written in competition for the prize which was conferred on Dr. Harris for his work, entitled 'Mammon;' or Covetousness and its Effects,' which was written in a singularly unobjurgative disposition, and was content to labour perseveringly for the public instruction, although his immediate reward was but small. His principal works were reprinted at low prices, and had extensive circulation in the hands of those who obtained them from them. A public subscription on his behalf, as an acknowledgment of the benefits he had conferred upon society, was projected a few years since by some of his admirers,
but realised a very small amount, most of it being raised in
the town of Dundee, where the subscription was commenced.
Dr. Dick’s works have been reprinted and very extensively
sold in the United States. Dr. Dick resided in the small
village of Drought, Perths, on the left bank of the river
Tay, in Forfarshire. Besides instructing the public by his
pen, Dr. Dick had been in the habit of accepting occasional
appointments to preach in neighbouring churches, and also
to deliver popular lectures on scientific subjects. A few
years ago a small pension was granted to him by the govern-
ment in acknowledgment of his services in the advancement
of popular sciences. He died July 29, 1837.

DICTYOGEN, B. a class of plants, proposed by Lindley, and
adopted in his Vegetable Kingdom. It seems to be
remarkable for the wide distribution of its species among
the larger classes of Exogens and Endogens. They have a monocotyledonous em-
by, but they have also a broad net-veined foliage, which
usually disarticulates with the stem. The following are the
natural orders of Dictyogenae: —

- Trivirgataceae.
- Discocasaeeae.
- Smilaceaeeae.
- Phaceszaeeae.
- Trillabeceae.

Flowers unisexual. Perianth free. Carpels
00; one seed.

Flowers unisexual. Perianth adherent. Carpels consolidated; several seeds.

Flowers bisexual. Carpels several, quite consolidated. Placenta axile. Flowers hexagonal, apetalous.

Flowers bisexual. Several carpels, quite consolidated. Placenta parietal. Flowers 3-6-petaloides.

Flowers bisexual. Several half consolidated. Placenta axile. Flowers 3-petaloides.

Flowers bisexual. Carpels solitary, simple, many-seeded, with long-stalked ana-
tropol seeds, and a basal placenta.

DIDYMOPIRUM. [Dicyphy, S. 2.]

DIEGO, SAN. [Canada, S. 2.]

DIGENITE, a native Sulphur of Copper.

DILMAN, a town in Perú, is situated on the caravane route from Trabiz to Erzerum, 70 miles W. from Trabiz, 20
miles W. from the north-west angle of Lake Urmiah, and
has about 16,000 inhabitants. It is situated in the wide and
fertile plain of Selimias, which stretches westward from the
lake to the base of the Kurdish Mountains. The town is
surrounded by gardens and orchards, and has clean streets.
The plain about it is inhabited by Nestorians, Armenians,
Catholics, Kurdish Leks, and Russian emigrants. About 4
miles to the westward is the old town of Dilman, a great
portion of which is in ruins. From the number of mounds
in it, and from the great size of some of them, it appears
an able extent, and it is described by St. Martin as being a very
ancient Armenian city. (Colonel Sheil, in London Geogra-
phical Journal, vol. vi.)

Birds. Several species of birds probably extinct, the
remains of several species of which have been found in New
Zealand.

In November, 1839, Professor Owen exhibited, at a meet-
ing of the Zoological Society of London, the fragment of
the shaft of a femur, 6 inches in length, and 2 inches in its
smallest circumference, with both extremities broken off.
This bone of an unknown struthion bird of large size,
assumed to be extinct, was put into the Professor’s hands
for examination by Mr. J. E. Nelson, of New Zealand, who
had recently been in New Zealand, where the natives have a tradition
that it belonged to a bird of the eegle kind, which hasecome extinct, and to which they give the name Movie or
Mouse. Similar bones, it was said, were found buried on the
banks of the Waikato.

After a minute description of the bone, Professor Owen
made the following statement: — There is no bone of
similar size which presents a cancellous structure so closely
resembling that of the present bone as does the femur of the
structure into which it is inserted, at the middle of the shaft, where the parietes of the medul-
lar or rather air-cavity, are smooth and unbroken. From
this difference I conclude the struthion bird indicated by the
fragments was not the heathen, of the sloughy species than the ostrich; its femur, and probably its
whole leg, was shorter and thicker. It is only in the ostrich’s femur that I have observed superficial reticulate impressions
similar to those on the fragment in question. The ostrich’s
femur is subcompressed, while the present is cylindrical,
approaching in this respect nearer to the femur of the emu;
but its diameter is one-third greater than that of the largest
emu’s femur with which I have compared it. The bones of
the struthion birds are more massive than those of the
great species, to daphoenus, are solid throughout; those of the crocodile he indicates the structure
like the present bone. The cancellous structure of the mamma-
rous long bones is of a much finer and more fibrous character than in the fossil. Although I speak of the bone
under this consideration, I believe it to be observable that it does not present the
characters of a true fossil; it is by no means mineral-
ised; it has probably been on or in the ground for some
time, but still retains most of its animal matter. It weights
7 ounces 12 drachms avoirdupois.

The discovery of a new struthion bird in New Zealand is one of peculiar interest, on account of the
remarkable character of the existing fauna of that island,
which still includes one of the most extraordinary and ano-
malous genera of the struthion order; and because of the
close analogy which the event indicated by the new fossil
offers to the extinction of the Dodo of the island of the
Mauritius. So far as judgment can be formed of a single
fragment, it seems probable that the extinct bird of New
Zealand, if it may be so called, was at least as well adapted
nearly resembling those of the Dodo than of any of the existing Struthionidae. Any opinion however as to its spe-
cific form can only be conjectural. The femur of the Stilt-
Bird (Himantopus) does not reveal the anomalous development of the other bones of the leg, but as my skill in interpreting an osseous fragment may be credited, I am willing to risk the reputation for it on the statement
that there has existed, if there does not now exist, in New
Zealand, a struthion bird nearly if not quite equal in size to the ostrich.

It was not long before an opportunity occurred of testing this very remarkable statement, and of proving the
capacity of the naturalist who had thus staked his reputation upon his conviction of the truth of the general principles of the
science of comparative anatomy. Professor Owen received
a communication from the Rev. W. Cotton describing several
other remains of animals of the same kind, and in 1843 a
collection, comprising vertebrae and bones of the hinder
extremities, pelvis, &c., were transmitted by the Rev. W.
Williams to the dean of Westminster (Dr. Buckland); and
in 1846 many specimens were sent to England by Dr.
Macmillan, Mr. Percy Earl, and Colonel Wakefield. These
were placed in the hands of Professor Owen, and form
the subject of his first and second "Memoirs on the Dinornis," in the "Zoological Transactions," vol. iii.

In these Memoirs Professor Owen pointed out that the bones which had been sent over from New Zealand contained the remains of no less than a remarkable group of birds, which he at first supposed belonged to the family of Struthionidae. Subsequent examina-
tion however has led Professor Owen to the conviction
that, although the two birds are not closely connected structurally and physiologically with the ostriches as with any other group of recent birds.

From an examination of the various bones thus collected, Professor Owen was enabled to point out that the fragment of bone which he had first received belonged to a species of the genus not only much larger than any of the other species indicated by these remains, but larger than any form of existing bird. To this species he gave the name of Dinornis gigas, and he determined that the height of the male had been from 10 feet to 10 feet 6 inches. The other species described were — D. ingens, attaining a height of 9 feet; D. struthoides; D. dactylopus, 4 feet; D. dromomæus, 5 feet; D. struthiodgacaudatus, 6 feet. In addition to these were described — D. curtus, D. croesus, and D. caurinus. Thus these remains showed the existence of a number of birds, varying in size from the almost flightless Bustard to birds of the size of the Dodo, the Emen, and the Ostrich, all of which

On a subsequent examination of the bones of D. ingens and D. dromomæus, Professor Owen discovered a back toe which he had seen nowhere in the other species, and for these he proposed the generic name Palæopteryx. To these birds was added the skeleton of D. curtus. Dr. Mantell gives the following account of a further discovery of the remains of birds in New Zealand: —

In 1846 and 1847 my eldest son, Mr. Walter Mantell, of Wellington, who had resided several years in the colony,
explore known every locality of these fossil bones within
his reach in the North Island, and went into the interior of
the country, and located with the natives, for the purpose of
collecting specimens, and of ascertaining whether any of these
genera, or others, had been formed, from the following facts;
that every bed of a loose bottom, almost 100 feet thick, covering a deposit of finely-laminated
sand, which covers a thick stratum of blue clay full of shells.
The conglomerate consists of pebbles and large boulders of
an inch or more in diameter, which are almost entirely of the
most visible bed; the shells it contains are marine, and
ressemble species existing in the South Pacific Ocean; but I
suspect many will be found specifically distinct from any
recent forms. Between the two bluffs near the embouchure of
lakes of which the bones of the Waikato are deposited, and
this on my first visit was strewn with bones of men, moa
and other birds, and two species of seals. I had some deep
openings made near the foot of the ancient cliff on the top of
which is the Pa or native village of Kurata, Z. diversi, the
to the same level as the flat on which I had observed the strew
fragments of bones I came to a regular ossiposiferous deposit.
The bones however perfect were as soft and plastic
as putty, so that if grasped strongly they changed as it were
by magic into pieces; and it was necessary to dig them up
with great care, and expose them to the air and sun to dry,
before they could be packed and removed. Unfortunately
the natives soon caught sight of my operations, and came
down in swarms, men, women, and children, trampling on the
bones, and destroying them. I was in a state of great anxiety,
lest I should without any notice I might have observed I
myself, or any one else, have overlooked any bones. The
end of the bones I had seen. The work was easier than
expected, and of a number of bones has been collected.
The chief part of this collection is now deposited in the
British Museum.

The locality from which these specimens were obtained is
described by Mr. Mantell:—"Near Waikorati, 17 miles
north of the head of the Waikato, and three-quarters of
a mile in length and 150 in height; it consists of sandy
clay distinctly stratified and traversed by
dikes of columnar trap, the columns being at right angles
to the layers of clay. In a little sight, south of Island
Point, on the side of the Waikato, the marl, which
the mainland at the entrance of the River Waikorati in front
of the native Kaiks, named Makuku, is situated the exposed
parts of the so-called turbar deposit, whence bones of Moa
and other birds of various kinds have been obtained in such
large numbers and perfection. This bed is about 3 feet in depth
and not more than 100 yards in length, and lies immediately
on a stratum of tertiary blue clay; its inland boundary is
otherwise denoted by vegetation, and appears to be of a very limited
extent; the bed is entirely subaqueous, and only visible when
the tide has receded. It consists almost wholly of decayed
vegetable matter, and its surface is studded with the undis-
turbed roots of small trees, which appear to have been burnt
to the ground at some remote period. It is a light, sandy,
elastic earth, of a blackish-brown colour, and emits a strong
fetid odour when first collected; from the large quantity of
animal matter it contains I conceive it was originally a
swamp or morass, in which the New Zealand Flax (Phormium
tenax) grew in larger plantations than the piper, not not by the
first layer of sand when exposed at low water... Although
bones of several species of Moa, especially of the largest
kinds, have been collected from this locality in considerable
numbers, and in great perfection, yet as the bed is rapidly
diminishing from the land to the sea, and the exportation
of bones by the tides, I fear that it will be entirely washed away, without yielding
to the palaeontologist all the desired information respecting
the extinct animals whose relics it enshrines; for the natives
and whalers are well aware of the interest attached to the
bones by Europeans, and they seize indiscriminately on any
specimen exposed by the receding tide, and if it cannot be
readily extracted they break it off, and thus many a valuable
relic has been destroyed. Their capricity and avarice have
too been so much indulged by the latter, that casual visitors, that the cost of specimens has increased to an unreasonable amount."

In their general aspect the bones which have been obtained from these spots closely resemble those obtained from the
oosiferous cavans in Germany. Professor Cotta gives a
analysis of their chemical composition, and from this infers
that they may have been recently deposited. Mr. Mantell
describes the bones also from North Island:—"On the western
shore of the Hokianga, about 30 miles north of the mouth of
the river; the Waipoua, for a distance of 40 miles, has a
complete canal for the small boaters at the back part of
the proximal end of the taro-metatarsal; the perforation
above the interspace between the outer and middle meta-
tarsals for the tendon of the adductor muscle of the fourth
toe, and the more distal part of the sole for the inner
toe—all concur to indicate the generic distinction of the
bird to which it belonged from either Dinornis or
Palapteryx; and I propose to distinguish the new genus by
the specific name A. oblonga, "taro-metatarsal..."

With the remains of the bones found on the banks of
the river Waikorati were mixed the fragments of egg-shells.
The eggs to which the fragments belonged were supposed to
belong to a species of bird similar to those about
subject to the recent discovery of a large egg in Madagascar
is interesting.

In a report to the French Académie de Sciences, M. Indres
Geoffroy St. Hilaire described three enormous fossil eggs
existance of a line of cliffs which extends inland, and has
manifestly been produced by the corrodion action of the
river. Driven from its course probably by a change in the
relative level of the land and sea, a stream of waterains its
course. If for instance a bed of loose soil has formed
its rate, 100 feet thick, overlying a deposit of finly-laminated
sand, which covers a thick stratum of blue clay full of shells.
The conglomerate consists of pebbles and large boulders of
an inch or more in diameter, which are almost entirely of the
most visible bed; the shells it contains are marine, and
ressemble species existing in the South Pacific Ocean; but I
suspect many will be found specifically distinct from any
recent forms. Between the two bluffs near the embouchure of
lakes of which the bones of the Waikato are deposited, and
this on my first visit was strewn with bones of men, moa
and other birds, and two species of seals. I had some deep
openings made near the foot of the ancient cliff on the top of
which is the Pa or native village of Kurata, Z. diversi, the

With the remains of the bones found on the banks of
the river Waikorati were mixed the fragments of egg-shells.
The eggs to which the fragments belonged were supposed to
belong to a species of bird similar to those about
subject to the recent discovery of a large egg in Madagascar
is interesting.

In a report to the French Académie de Sciences, M. Indres
Geoffroy St. Hilaire described three enormous fossil eggs
from Madagascar, and some bones belonging to the same bird. The captain of a merchant-ship trading to Madagas- 
car, who had a very large collection of specimens of Psopho-
notornis giganteus, which is one of the birds found in the Zoological Society. An almost perfectly restored skeleton of the Dinornis giganteus exists in the Museum of the Col-
lege of Surgeons. Professor Owen concludes one of the 
memorials referred to with the following general remarks:—
The extraordinary number of wingless birds and the vast 
number of the peculiar species peculiar to New Zealand, and 
which have finally become extinct in that small tract of dry 
land, suggest it to be the remnant of a larger tract or conti-
ent over which this singular Struthion-Fana formerly roamed. One might almost be disposed to regard New 
Zealand as one end of the mighty wave of the unstable 
and ever-shifting crust of the earth, of which the opposite end, 
after having been long submerged, has again risen with its 
accumulated deposits in North America, showing us in the 
Connecticut Sandstone of the Permian period the foot-prints 
of the gigantic birds which trod its surface before it sank; 
and to surmise that the intermediate body of the land-wave 
along which the Dinornis may have travelled to New 
Zealand has progressively subsided, and now lies beneath the 
Pacific Ocean.”

(Own, Memoirs on the Dinornis; Zoological Tran-
sactions, vol. iii.; Owen, Proceedings of Zoological Society, in 
Annals of Natural History; Mantell, Fossil Fossils and their 
Teachings.)

DIOMEDÉEN, a family of birds, to which the Alba-
crese belong. The characters of the genus Diomedea are 
given under ALBATROS. In that article three species of this genus are 
recorded. We give a complete list of the 
species of this important genus—

D. diomedea, Linn. This bird is abundant between 
30° and 60° S. lat., and equally numerous in all parts of 
the ocean bordered by those degrees; its range, however, 
extends much farther south, even to within the antarctic 
circle.

D. melanophris, Temm. It is the most abundant species 
of the southern seas; equally numerous in every part between 
the 30th and 60th degrees.

D. caieta, Gould. This species was procured by Mr. 
Gould off the Island of Van Diemen’s Land.

D. chlororhyncha, Lath. It occurs between 30° and 60° 
S. lat., in both the Atlantic and Pacific Oceans.

D. culminata, Gould. This bird is rather abundant both in 
the Pacific and Atlantic Oceans, between 30° and 60° S. 
lat.

D. fuligina, Gmel. It occurs in all parts of the ocean 
between 30° and 60° S. lat.; equally common off Van Die-
men’s Land, Cape Horn, and the Cape of Good Hope.

D. brevipes, Gmel. In the North Pacific Ocean.

D. gibbons, Gould. An inhabitant of the North Pacific 
Ocean.

D. olivacea, Gmel. China seas (?). Mr. Gray, in his ‘Genera of Birds,’ also 
lives D. spectabilis as a species. It is abundant in the Atlantic Ocean, with 
and adopts the latter name as having the priority.

DIOPSIDE. [A.QUITA.]

DIPHTHERITE. [MATERIA MEDICA, S. B.] DISRAELI, ISAAC, was born at Enfield, Middlesex, in 
1766. His father, Benjamin Disraeli, was the descendant of 

D. fuligina, Gmel. It occurs in all parts of the ocean 
between 30° and 60° S. lat.; equally common off Van Die-
men’s Land, Cape Horn, and the Cape of Good Hope.

D. brevipes, Gmel. In the North Pacific Ocean.

D. gibbons, Gould. An inhabitant of the North Pacific 
Ocean.

D. olivacea, Gmel. China seas (?). Mr. Gray, in his ‘Genera of Birds,’ also 
lives D. spectabilis as a species. It is abundant in the Atlantic Ocean, with 
and adopts the latter name as having the priority.

DIOPSIDE. [A.QUITA.]

DIPHTHERITE. [MATERIA MEDICA, S. B.] DISRAELI, ISAAC, was born at Enfield, Middlesex, in 
1766. His father, Benjamin Disraeli, was the descendant of 
a family of Spanish Jews, who, driven from the Peninsula in the 
10th century by the persecutions of the Inquisition, had settled 
in Venice, and there, to mask their race, had exchanged the 
Gothic Spanish name they had hitherto borne for that of 
Disraeli—"a name never borne before or since by any other family 
(the name was originally written D’Israël; but in his later years the subject of this memoir was in the habit of 
omitting the apostrophe). He had come over from England 
and from Italy in 1748, and made a considerable fortune by 
commerce. He married in 1765 "the beautiful daughter of a 
family" of his own race "who had suffered much from persecution. "She was a person of strong sense but no 
esthetic or fancy for fancy, and in the main a useful woman, of 
her race." The only child of this union was the subject of our 
notice. His sensitive and poetic character as a boy puzzled 
both his parents, and, in particular, occasioned continual 
complaints from his father, that he and his mother had 
"bred a fool, and thus ruined him and the family to the 
ruin of his sight and fortune." But from the first he showed 
a decided aversion to an active life. Educated first at a school near 
Enfield, and then at Amsterdam, where the only advantage 
he received was that derived from access to a large library, 
he was not more than eighteen when, in spite of all that his
father could say or do, he signified his intention of being a literary man. "He had written a poem of considerable length, which he wished to publish, against commerce," his father naturally opposed this intention, and accordingly on one occasion "Dr. Jarratt, in the statement of his case, complaining that he had never found a counselor or literary friend. He left his packet itself at Bolt Court, where he was received by Mr. Francis Barber, the junior, in a black servant's dress, to call for, 'two or three times a week.' When he did call the packet was returned to him unopened, with a message that the doctor was too ill to read anything. The doctor, in fact, was then on his deathbed. In 1788 Dianas's father sent him to travel in France. On the way he met Dr. Maitland, a shadowy Chartist. At some point in the conversation he ventured anonymously to publish by way of corrective some verses "On the Abuse of Satire," which Walcott attributed to Hayley. About this time he became acquainted with Mr. P. F. afterwards poet laureate, who was of service to him in many ways, and who persuaded his father to allow him to follow his own inclinations. Accordingly from about 1790, without any further opposition on the part of his family, and with sufficient means supplied by his father (who survived till 1819, when he was nearly ninety years of age), he was free to devote himself entirely to literature. His first efforts were in poetry and romance. His early verses are forgotten; but a volume of romantic tales, including one called 'The Loves of Me neuen and Loo.' Some time after this, in the middle of the 18th century, a second edition appeared. But though he had a poetic taste, he was not fitted to be a poet or creative writer; and he was not long in finding out that his true vocation was in the history of society. A series of works illustrative of its literary and political history he could call "several other words," and these were researches in literature and history and gossips. It was in the year 1790 that he published anonymously a little volume entitled "Curiosities of Literature." The success of this volume determined him to prosecute the walk which had there entered upon. Accordingly, with the exception of the volume of romance above alluded to, and we believe, one or two other anonymous publications, all Mr. Diaries's further productions during his long life consisted of the fruits of his literary labors. These researches were prosecuted partly in the British Museum, where he was a constant visitor at a time when the readers who had access to its treasures were not more than half-a-dozen daily; partly in his own library, which, especially in the end of his life (when he resided on his own manor of Bradenham in Buckinghamshire) was very extensive. The results of these researches were put forth from time to time either as additions to his "Curiosities of Literature" (which thus eventually amounted to six volumes, published in 1789, 1790, 1797, 1806, 1807, of six volumes); or as independent publications. Among these independent publications may be mentioned his "Essay on the Literary Character" originally published in 1790; his "Anecdotes of Literary Controversy," and his "Inquiry into the Literary and Political Character of the First."—works originally published between 1812 and 1822, and since then published collectively under the title of "Miscellaneies of Literature;" and his "Life and Reign of Charles the First," published in five volumes at intervals between 1828 and 1831. In acknowledgment of this last work he was made D.C.L. by the University of Oxford. He contemplated a "Life of Patrick Colquhoun," and had collected materials for both; but a paralysis of the optic nerve which attacked him in 1839 prevented him from executing either. With the assistance of his daughter he selected from his manuscripts three volumes, which were published in 1841 under the title of "Amunities of Literature." His last years were spent in revising and re-editing his former works; and he died in 1843 at the age of 82. "He was," says his son, from whose memoir prefixed to a new edition of his "Curiosities of Literature," "a character of the literary character, a man who really passed his life in his literary labors. Even marriage produced no change in these habits: he rose to enter the chamber where he lived alone with his books, and tea was served in the same "wainscots." In his old age his appearance changed, he became more mild and venerable; he had then become rather corpulent.

Diss. [Norfolk.] "Divorce. The subject of the law of divorce has for several years engaged the attention of the legislature, and a commission having been appointed to consider the question, made a report which was presented to both houses of Parliament by command of Her Majesty in 1833. The statute 30 & 31 Vict. c. 56, which came into operation on the 11th day of July, 1835, has completely altered the recommendation of the commissioners into effect. For information as to the previous state of the law, see Divorce.

In the first place the jurisdiction in matters of divorce and causes connected therewith is in the High Court of Justice, which consists of the Lord Chancellor, the Lord Chief Justice of England, the Lord Chief Justice of the Common Pleas, the Lord Chief Baron of the Common Bench, the Lord Chief Justice of the Court of Exchequer, the junior puisne judge in each of the three Common Law Courts, and the judge of the Court of Probate. In the last-mentioned functionary is entitled the 'Judge Ordinary of the Court of Divorce and Matrimonial Causes,' and he is invested with power to determine alone all matters, except petitions for dissolving or annulling marriage, applications for new trials, bills of exception, special verdicts, and special cases.

The Act abolishes the old decree of divorce a mensa et thoro, but enables the judge to pronounce a sentence of 'judicial separation,' which is nearly the same thing, and which sentence may be obtained either by husband or wife, and is a sentence which, if not barely a separation, is a cause for two years or upwards. Desertion was not a ground for legal separation under the old system, which only offered to the party wronged such remedy as was afforded by a decree for the restitution of the community of property. The Act also contemplates that in the sentence of judicial separation has over the old divorce a mensa et thoro, consists, however, in this, that from the date of the sentence, and whilst the separation continues, the wife is considered as a feme sole with respect to her property, if every demand of the separation may be put an end to, either by the reversal of the decree or by the mutual consent and actual cohabitation of the parties, but in the latter case the property of the wife acquired subsequently to the separation is still held to her separate estate, if she consents to cohabit. The husband and wife may enter into while separate.

Applications for judicial separation and restitution of conjugal rights may still be made as before. The statute goes as far as to provide that a marriage may be put an end to, either by the reversal of the decree or by the mutual consent and actual cohabitation of the parties, but in the latter case the property of the wife acquired subsequently to the separation is still held to her separate estate, if she consents to cohabit. The husband and wife may enter into while separate.

Applications for judicial separation and restitution of conjugal rights may still be made as before. The statute goes as far as to provide that a marriage may be put an end to, either by the reversal of the decree or by the mutual consent and actual cohabitation of the parties, but in the latter case the property of the wife acquired subsequently to the separation is still held to her separate estate, if she consents to cohabit. The husband and wife may enter into while separate.
for dissolution of marriage, he may at the same time claim damages from the adulterer, who must be made a respondent. The damages are ascertained by the verdict of a jury, the old action of crim. con, being abolished by the statute. The adulterer may also be condemned in the costs of the whole proceedings.

After a decree of dissolution has been duly pronounced, either party is at liberty to contract a new marriage. Out of respect, however, to the religious scruples of a part of the community, clergymen of the established church are not compulsory to perform them, he was afterwards released from the bonds of a former marriage. In case of a general refusal on the part of the clergy to celebrate marriages under such circumstances, parties so situated may of course marry with the other formalities by which that course is regulated.

DOBRENTÉI, GABOR or GABRIEL, an Hungarian author and antiquary of distinguished merit, was born at Nagy-Szőlős, in the county of Vasprám, in 1766. He showed very early not only a remarkable zeal for the Hungarian language and literature, but a singular social talent for enlightening others in his views. At Eödesen, a town not far within the frontier from Austria, and chiefly inhabited by Germans, he succeeded in getting up an Hungarian literary society, of which he became the secretary; and under his auspices, the Hungarian Transactions was published. At twenty he studied at Witttenberg and Leipzig, and in 1807 was recommended by Kinczyczy, then the almost acknowledged head of Hungarian literature, to the post of tutor to the Exiles of Leopold, which made him for some years a resident in that country. With the literary contributions of some of his Hungarian and Transylvanian friends, and the pecuniary contributions of the Transylvanian magnates, he set on foot and edited a magazine, the Exilés' Museum, of which the first number was issued at Klansenburg and the remaining nine at Pesth, after which it ceased for want of support; but it contained so many articles of interest that no Hungarian library is considered complete without it. Pesth was his permanent residence for the remainder of his life, in the occupation of several highly respectable official posts of a legal character, and in such constant literary activity that he became the acquaintance or friend of almost every person of any note connected with Hungarian literature. Indeed almost all the information that has been put in circulation on that subject in England had its origin in Dobrentei. He was the friend and correspondent of Dr. now Sir John Bowring, to whom he supplied much of the information used in his valuable productions. Correspondence was exchanged with Miss Padroe for her account of Hungarian literature and authors in her 'City of the Magyar,' and he wrote the article on the subject in the Leipsie Conversations-Lexikon, which, by its being translated into the English and French Encyclopedias, and the translation reprinted in the Glasgow Popular Encyclopaedia, has become familiar to thousands of English readers. As a poetical writer, Dobrentei was not successful; his original poems appear to have been pleasing, but no more; and though his translation of Shakspere's Macbeth was acted at Brussels in 1825, it did not receive such a welcome as to encourage the publication of his versions of the other masterpieces of Shakspere, which were reserved in Hungary for the more successful pen of a lady, Emilie Lemoine, who in 1832 translated the whole of our great poet in any language. Dobrentei was more at home in his exertions to establish a Casino at Pesth, an establishment of nearly the same kind as an English club of our own country, but more numerous, a noble project, but being frustrated the post to take that of one of the secretaries of the Hungarian Academy in 1833, of which he was also a zealous promoter.

Kohli, the traveller, bears testimony to the extraordinary influence of these establishments on the whole tone of the Transylvanian aristocracy, and an imitation of the modern style in art was imitated on a small scale. In 1837 Dobrentéi received an intimation from the government that his holding the post of secretary to the Academy any longer would be incompatible with his occupation as a member of the circle of the editorship of his great work, the 'Regi Magyar Nyelvemlékek,' or 'Ancient Monuments of the Magyar Language,' the first volume of which, a substantial quarto, was published at Buda in 1825, and the fifth was in process of publication at the time of Dobrentéi's death. His labours on this work were the delight of his life, he pursued them with irrepressible ardour, and on the result his reputation rests securely. When he began, hardly anything was known of the history of the Magyar language and literature, and in his study in darkness he left environed with light. He was indefatigable in discovering the existence of old correspondence or documents in family archives; when he had once discovered them, he was as eager in obtaining permission to copy and make use of them, as if he was himself the owner of a rare and costly manuscript. By this combination of qualities he amassed a quantity of materials which nobody before him had ever supposed to exist, and he made such good use of them that his works of literature and history of the greatest importance to Dobrentéi's 'Nyelvemlékek,' which has become one of the principal monuments of Hungarian literature. How the revolution of 1848 affected him we have not seen stated, but it is well known that his friend and fellow-promoter of progress, Count Stephen Széchenyi, became a maniac. Dobrentéi was still engaged in collecting materials for his great work when surprised by death on the 27th of March 1851, at the age of 65. He was the author of numerous lives of Hungarian worthies, and in 1839 he published for which he contributed in the 'Eszterházy Társ,' or Hungarian Journal, of the Leipsie Conversations-Lexikon, with original additions to the Hungarian articles, and in editions of Berzenyi and other authors published under his superintendence, but the work of himself appears to have been published since his death.

DOBUDRUSKA, a district in European Turkey, forms the north-eastern part of Bulgaria, and comprises the country north of the eastern rampart called Trajan's Wall, between the Danube on the north, and the Black Sea on the south. Trajan's Wall leaves the Danube between Rasova and Csernava, and runs across to the Black Sea a little south of Kustenje, a distance of about 35 miles. In its western part the work is a small stream, the Kara-Su (Black Water), that connects with another extended to the Danube above Csernava. At the head of the valley of the Kara-Su, near Bourik, a line of hills or downs, composed chiefly of a porous limestone rock, runs north and south 164 feet above the level of the Black Sea. Along the coast at Kustenje also there is an uninterrupted range of low hills and cliffs, so that it is certain the Danube never had an outlet across the Dobrudjaka in this direction. The formation of a canal from Csernava to Kustenje has been long a subject of speculation, and in the summer of 1848 a canal of porous limestone, no water ever rests to feed such a canal if it were cut. Besides, the only water communication between these two points that would be of much use would be a ship-canal, but even in these words, the opening of a new bed for the Danube; and this the nature of the ground renders all but physically impossible.

The low undulating down runs northward all through the Dobrudjaka, forming a small watered rift between the Danube and the sea; on the north it joins a lofty mountainous mass, which covers the north of the district between Baba-Dagh and Matchin. On the eastern side the Dobrudjaka is marshy, and contains several lakes. There is a great scarcity of drinkable water in this district. It contains however many great lakes, although in the hot season of the year, like all the countries near it, it resembles a desert. In the spring, on the melting of the snows, the soil is saturated with wet, and in most parts is converted into a sea of mud. The inhabitants are chiefly Bulgarians, Greeks, and Turks, the latter who rear sheep and buffaloes. Eagles, ostriches, cranes, wild geese, partridges, kites, ducks, wild swans, and wild dogs, are extremely numerous in the Dobrudjaka. Along the Danube are the fortresses of Hirsova, Matchin, Isaakitch, and Tulca, although in the interior of the town of the Danube, which forms part of the boundary between the Dobrudjaka and Russia. In the interior is the town of Baba-Dagh, between the mountains of that name and Lake Rasov. Kustenje is a mere village. In 1804 a Turkish army fell back to the fortress of Silistria, where they defended themselves successfully.

DOG-PIGH. [SQUALILO.] DONINGTON. [LEICESTERSHIRE.] DONINGTON, CASTLE. [LEICESTERSHIRE.] DONIZETTI, GAETANO, was born September 25, 1798,
at Bergamo, in Northern Italy. He studied in the Lyceum of that town, and his father having originally destined him for the Church, he received a good classical education and then proceeded to musical studies. He received his first instruction at the Musical Institute of Bergamo, of which Simone Mayer was then director. Here he remained three years, and in 1816 he moved to Boigny, where his musical education was completed. He then went to Maastricht, and entered the army. He dedicated his life to music. In 1818 he published his first opera, 'Enrico di Borgoja. He continued to write for the stage and was a frequent visitor to his home in Milan. His earliest works, however, are forgotten, or at least are no longer performed, and it was not till 1830, when he produced 'Anna Bolena,' at Milan, that he began to take rank with the higher class of musical composers. In the course of these first twelve years of his career he composed over 130 operas, and the four years from 1844 to 1847, when his last opera, 'Catarino Cornaro,' was performed, he produced 33 operas, of which several have sunk into oblivion, but others still retain their places on the stages of Italy, Germany, France, and England. Some are especial favourites, and frequently performed. Among these more fortunate productions may be mentioned 'Anna Bolena,' Milan, 1830; 'L'Elixir d'Amore,' Milan, 1833; 'Lucrècia Borgia,' Milan, 1833; 'Marino Faliero,' Paris, 1836; 'Lucia di Lammermoor,' London, 1835; 'Le Roi d'Ys,' Paris, 1836; 'El Fille du Régiment,' Paris, 1840; 'La Favorita,' Paris, 1840; 'Linda di Chamouni,' Vienna, 1843; 'Don Pasquale,' Paris, 1843; 'Maria di Rohan,' Vienna, 1843. Most of these later operas, besides his usual grace and facility, exhibit a certain amount of melodic interest, and some degree of construction and skill in instrumentation, much superior to his earlier productions. His artistic powers were thus manifestly improved and expanding towards the termination of his musical career. Soon after the performance of his 'Lucia,' which excited great admiration, he was appointed Professor of Counterpoint in the Royal College of Music at Naples, and after the production of 'Linda' at Vienna, he was named chapel-master and composer to the imperial court. In 1844, which was the year of mental labor, he described all those vices and habits of intemperance, began to show themselves, and he was for some time in a lunatic asylum. In October 1847 he was removed to his native town of Bergamo, where he died on the 9th of April 1848. (Neuvième Biographie Générale.)

DONOSO CORTÉS, JUAN, an eminent Spanish statesman and author, was born in 1609, of wealthy parents, at the town of El Valle in Extremadura. He was so precocious that at the age of eleven he studied logic at Salamanca, and had entered upon a political career before he was of age to enter on a legal one. A pamphlet however which he composed under the title of a 'Memoir on the Rights of Isabel the Second,' was suppressed by the advice of his friends as contrary to the constitution. Having been Igno 10, 1822, when the temporary revocation by Ferdinand of the decree for the succession of the present Queen Isabel awakened the apprehensions of the liberal party that all political liberty was at an end, he was sworn a member of the principal young men of Madrid waited on Queen Christina to offer her their lives in defence of the rights of her infant daughter, and at their head was Donoso Cortés. From this time he was distinguished by the favour of Queen Christina, and entered upon a political career before he was of age to enter on a legal one. A pamphlet however which he composed under the title of a 'Memoir on the Rights of Isabel the Second,' was suppressed by the advice of his friends as contrary to the constitution. Having been imprisoned for some time he was called to the ministry of Grace and Justice, and in the next published his 'Considerations on Diplomacy and its Influence on the Political and Social State of Europe, from the time of the Revolution of July that of the Quadruple Alliance.'

In 1833 he was sent as a royal commissioner with General Rodil to bring back to obedience his native province of Extremadura, and acted with such success as to receive the grand cross of the Charles I of Spain, a high official station; but dissatisfied with the turn that affairs were taking, he resigned and retired to the army, and for some time occupied himself in combating the party which supported the revolution of La Granja. He founded the newspaper 'El Píldor,' in which he was assisted by Alcalá Galiano, and at the same time was the editor of the 'Revista de Madrid,' a review or rather magazine established on the plan of the French 'Revue des Deux Mondes,' his first article in which was one of a series on 'Spain since 1834.' He delivered in 1837 at the Athenaeum of Madrid, a series of lectures on the social structure of the Spanish nation which excited much attention. He was in France in 1840 at the time of the expulsion of Queen Christina, hastened to offer her his services on her arrival in that country, and is said to have been the author of the manifesto which she issued from Madrid. He was at the war councils of Paris in the 'Revista de Madrid,' and have received high applause from Spanish critics. He returned to Spain in 1844 after the fall of Espartero, and was named plenipotentiary to invite Queen Christina back to Madrid, when his services were rewarded with the grand cross of Alcalá Galiano, which he never ceased to be active, was by this time active in an entirely different cause from that in which he had first won his laurels. From an ultra-liberal Donoso Cortés had become a Catholic conservative, and after Palmerston, the most distinguished literary advocate of Catholicism in Spain. He was ambassador to Prussia at the time of the revolution in 1848, and afterwards ambassador to France, a country for which he always avowed a strong partiality. It was while holding that office that he died on the 3rd of May 1853, at Paris.

As to his writings, 'Colección Escogida de los Escritos del Excelentísimo Señor Don Juan Donoso Cortés,' was published in two volumes at Madrid in 1848. It comprises none of his poetry but most of his political writings that have been mentioned, and several of his articles from the reviews, which seem, like those of Macaulay, to be considered the brightest ornaments of his literary career. For brilliancy of style they are remarkable among the general flatness of Spanish composition, but for soundness of thought they are too rare to be chief ornaments of the literature of England. One of them, on Pius IX., talks of the "singular privilege which Italy enjoys in conjunction with Spain of drawing towards itself the attention of the civilized world," and goes on to affirm that "the nations always keep their eyes fixed by instinct on the Italian and the Spanish race."

There is much that is questionable on most of the subjects on which he touches.

DON. [AVROYD.] DOBBIN. [OXFORDSHIRE.] DORN. [SUTHERLAND.] DOUBLEDAY, EDWARD, a naturalist of eminence, was born in 1810, and died in London in 1849. The family of Doubleday are honourably distinguished for their devotion to natural science, and have occasionally distinguished himself by his contributions to the literature of Ornithology and Entomology. His first papers were devoted to the subject of entomology, of which many were published in the volumes of the 'Entomological Magazine.' The early part of his life he made a tour through the United States of America, and made many important observations on the animals of that country. These he published in a paper 'On the Natural History of America,' in the fifth volume of the 'Entomological Magazine.' On his return from America he was appointed one of the curators of the British Museum. The large collections in this institution afforded him abundant materials for increasing his knowledge and developing his views of the structure of insects. The results he made are found in a variety of papers, but more especially in his work 'On the Genera of Diurnal Lepidoptera.' This work, which was published in parts and left unfinished at the author's death, consisted of descriptions, with coloured illustrations, of great beauty and skill, of species of all the genera of butterflies. This family of insects was studied by Mr. Doubleday with the greatest industry, and his contributions to our knowledge of their forms are the most valuable of his labours. He devoted also a great amount of attention to the study of spiders, and published a work on this subject. He also contributed a paper 'On the Occurrence of Alligators in East Florida,' to the 'Zoologist.' A list of his papers will be found in the section of the 'Bibliotheca Zoologica,' published by the Ray Society.

DOWNHAM. [NORFOLK.]
**Dracoina**, a sub-family of Saurians belonging to the family *Agamidae*, the tribe *Strobloeca*, and the sub-order *Pachylosauria* of Dr. J. B. Gray's arrangement. The family of Agamas, or Agamidae, is thus defined by Dr. Gray: "Teeth implanted on the end of the jaws. Tongue short, depress'd, apex entire or slightly nicked. Eyelids constrict, valvar. Feet, for walking. Toes all free, unequal; the thumb of the hind feet on the same plane as the other toes; the little toe lower down on the ankle than the thumb. The thumb is anterior and internal, and the great toe of the hind foot occupies the same position, the thigh and foot being bent forwards. This is proved by analogy; this toe being one that is clawless in the Crocodiles, which have the clawless thumb, and in *Anolis*, where the thumb and great toes are simple and not dilated beneath, like the other toes."

The synopsis of the genera of this family, according to the 'British Museum Catalogue,' is as follows:

I. Body compressed. Living on trees.

a. Ribs elongated, exserted, supporting wing-like lateral expansions. Throat with 3 pouches.

1. *Draco.*—Ears naked. Nostril below the face-ridge.

2. *Dracocela.*—Nostril above the face-ridge.

3. *Dracocelum.*—Ears covered with scales.

* Toes 4 or 5. Ears exposed.

** Toes 5—6. Tail with elongated keeled scales beneath. Scales of back small, often with scattered larger ones.

* Ears hidden under the skin.

†† Ears exposed.

*** Toes 5—6. Tail with broad rhombic keeled scales beneath. Scales of back uniform.

**** Toes 5—6. Tail with truncated keeled scales beneath. Scales small, keeled, in cross rings.

The nape and back with a low crest. Tail rather compressed. Face-ridge rounded, with small scales.

16. *Charaxis.*—Parotis swollen, with some spines above. The nape and back with a low crest. Tail tapering. Face-ridge distinct, with enlarged imbricated scales.

17. *Gindalia.*—Parotis rather swollen, with 2 or 3 spines above. Nape and back not crested. Tail tapering, round. Face-ridge indistinct.

B. Femoral pores distinct.

18. *Lophora.*—Back and tail with a fin-like crest, supported by bony rays. Head squarish.

* Neck with a frill-like expansion on each side.

20. *Chlamydosaurus.*—Head rhombic.

** Ears simple.

25. *Grammatolophus.*—Back not crested, with cross rows of larger scales. Femoral pores numerous.

* Pre-anal and abdominal pores in several rows.

27. *Stellio.*—Tail with rings of large spine scales. Parotids spine.

** Pre-anal pores in a single line. Abdomen poreless.

* Ears exposed. Body and limbs with large spine tubercles.

34. *Uromastyx.*—Tail broad, depressed, with complete rings of spine scales.

35. *Saara.*—Tail broad, depressed, with scales of the upper part of the rings spine; of lower, armless.

36. *Latoilia.*—Tail round, elongate, tapering, with whorls of smooth scales.

The genera and species of the family *Dracoina* are as follows:

1. *Draco.*—Head small. Nostril in a scale, rather tubular on the side of the face-ridge. Tympanum of the ear visible, opaque, white. They live on trees, walking with agility with their wings folded on their sides, but they expand them and use them as a parachute when they throw themselves from the tops of trees. They spread out their pouches as they lie on the trunks of the trees. Scales unequal, some larger, keeled. Nape crested. For skeleton of *Draco*, see *Dracon.*

D. *volans*. Linn., the Flying Lizard. It is the *D. major* of Lamark, *D. viridis* of Daud. *D. Bournonii* of Lacoon, and the *D. Daudini* of Duméril. The scales of the back are rather broad, generally smooth; of the throat granular, of the same size; the lateral pouches of the males moderate, rounded at the end, covered with ovate keeled scales; the throat black-spotted; wings gray, fawn, or brown, spotted and marbled with black, sometimes forming four or five oblique black bands near the outer edge; the sides with a series of large keeled scales.

D. *Tenerum*, the Tiny Flying Lizard. It is the *D. viridis Tenerum* of Schlegel. It has flat scales, rather large, smooth, unequal, with a row of rather larger keeled scales upon and on each side of the vertebral line; wings reddish, brown-spotted; lateral pouches (of male) moderate, rounded at the end, covered with large keeled scales; sides with an interrupted series of large keeled scales.

D. *sensilis*, Kuhl, the Fringed Flying Lizard. Scales of the back small, equal, mostly smooth; the throat with many circular spaces, covered with large granular scales; head

3 B
white, brown-spotted; lateral pouches of male elongate, angular, acute, covered with large keeled scales; wings with short whitish longitudinal lines; sides with a series of small triangular keeled scales, placed in groups of two or three; nostrils sub-superior. For figure of Dracaena farmiliaris, see D. Rana.

2. Dracocela.—Head small, covered with small unequal scales; the nostrils roundish, in a scale, erect, vertical on the face-ridge; tympanum exposed, and opaque.

* Nape crested.

D. dussumieri, Dussumier's Dragon, has moderate scales, rather rough; toes with a series of rather larger scales placed in roundish groups; orbit with a small bony point at back and front angle; wings with large brown spots near the body, and largely marbled near the outer edge; a black hand across the throat; base of the pouch blue-black; the limbs moderate.

* Nape not crested.

D. nectarotopogon, the Red-Throated Dragon. The orbit with a small bony point above, upon the front and back edge; scales of the back equal, smooth, the sides with a series of large keeled scales; nape not crested; a large round black spot on each side of the base of the pouch; wings brown-spotted; the limbs elongate.

3. Dracunculus.—Head quadrangular, covered with small unequal scales; nostrils lateral, on the face-ridge; tympanum hid under the skin, covered with scales. Weigmann describes it as a small, but fine and well formed specimen in the British Museum, like the other dragons, have six on each side.

* Nape not crested, with a longitudinal fold.

D. guineofasciatus, the Banded Flying-Lizard. Wings with five cross bands; scales of the back keeled; nape with a longitudinal fold, not crested; nostrils superior, erect; ears covered with many equal granular scales.

* Nape crested. Ears slightly concave.

D. laticinctus, the Lined Flying-Lizard. Head gray, white-spotted; wings dark-banded, with small white longitudinal lines; the sides and throat bluish-black, with large white spots; the ears indistinctly marked, covered with three flat scales; base of the tail rounded over, with a slight crest on each side.

D. ornatus, the Banded-Head Dragon. Gray; head black, cross-banded; chin black, dotted; wings gray, reticulated with black, and with broad black bands at the edge; scales rhombic, of the middle of the back larger, keeled, of the sides smaller, smooth; ears covered with small equal granular scales; tail slender, compressed, with five keels above and two stronger keels beneath, rather depressed at the base, with the posterior ones slightly rounded.

D. maculatus, the Spotted-Winged Dragon. Gray; black-spotted; wings black-spotted; throat gray; pouch of the male elongate; scales of the back rather unequal, rhombic, keeled, or small; for smaller species of large keeled scales; ears rather sunk, with unequal flat scales; tail slender, with a central keel above and five more small ones on the sides; base dilated, with five nearly equal distant equal keels above.

D. splendidus, Weigmann's Flying-Lizard. Wings redish near the body, with large brown spots, yellow near the edge; throat yellow, black-spotted. This may be the same as the former species, but the wings are subelliptic, and the scales do not form a series.

D. DRAGON.FLY. [LIPSCULLA, S.1]

DRAKE, a genus of plants belonging to the natural order Orchidaceae. D. elatiusa has a single flower placed at the end of a slender smooth erect scape from 12 to 18 inches long, and its labellum, which is hammer-headed and placed on a long arm with a moveable elbow-joint in the middle, is stated by Mr. Drummond to resemble an insect suspended in the air and moving with every breeze.

DREELITE. [CALLONITUS]

DROXFIELD. [DERBYSHIRE]

DROZ, FRANCIS-XAVIER-JOSEPH, was born at Beaancon on the 31st of October, 1773. Having visited Paris in 1792 he witnessed the massacre of September; after which he returned to Beaancon, and enlisted as a volunteer during the national enrolments. His comrades, according to the fashion of the times, elected him as their captain. But after a short service of little better than three years, he quitted the army for ever in 1796, and devoted the rest of his life to study. About the same time he obtained by his family influence the appointment of Professor of Sciences at the University of Lille in his native town; and in 1799 he published his 'Essai sur l'Art Oratoire.' In 1812 he published in Lille a work on the Theory of History, which was highly appreciated by his contemporaries. He died in 1844, after a long residence in Paris, where he settled definitively, and became connected with Voltaire, Cabanis, and all the leading literary men of the time. The advice of Cabanis, he published his 'Laws,' a work which was published in 1834, to attract attention to his philosophical writings. In 1836 appeared his 'Essai sur l'Art d'etre Heureux,' which was followed by an 'Etude de Magenta,' in 1811, for which a medal was awarded to him. From 1816 to 1820 he wrote for several newspapers, inculcating his opinion of the views of modern political writers, and criticising politics. He then joined Picard in writing his 'Memoire de Jacques Fauvel,' a tame imitation of Gi Blas; the work appeared in 1832. The next year he carried off the Montyon prize for his treatise 'De la Philosophie, ou sur les differents Systemes sur la Science de la Vie.' In 1825 he was elected a member of the French Academy.

He had long desired to hold a professorship, and at length in 1832 he was appointed to lecture, by authority, at the Institute, on Moral and Political Science. In 1836 he published his best work, 'Histoire du Régne de Louis XVI.' His gentle and unambitious life came to a close on the 4th of November, 1850, when he died as peaceably as he had lived. Although his works are written in a very unpretending style, they are of theoretical importance, and were much valued by all the principal critics of his country have mentioned them with esteem.

DUCK-WEED. [Lemna.]

DUFFRENOYSITE. [Mineralogy, S.I.]

DUFFRENOY, a mineral, consisting of an arsenicite and sulphurised lead. It occurs in dodecahedrons of a dark steel-grey colour in the Dolomite of St. Gothard. The specific gravity is 5.

DUKE COLLEGE. Un under Astley, William, in the 'Penny Cyclopedia,' vol. i., p. 347, an account was given of the college of his institution. As the value of the property with which he had endowed it had enormously increased, it had been long felt, that the income was no longer sufficient for the stations and expenses of the college. An Act was therefore passed, 20 & 21 Vict. c. 84, for its better management. According to this Act, the educational branch of the college is very largely extended; two schools are established, an upper and a lower school, in which the classical and modern languages, mathematics, history and geography, physics, chemistry, civil engineering, and other departments of knowledge are to be taught to daily scholars, on the payment of a small fee, with no limit to the number except the amount of funds. Under the Act there are twelve exhibitions of 100l. a year each provided for the scholars of the upper school, tenable for five years while studying at an English university or for a profession; and twelve of 40l. for boys of the lower school, tenable for four years for the like purposes.

The life interests of the present master, wardens, fellows, and poor brothers and sisters are provided for; but for the future management nineteen governors are to be chosen; namely, two to be elected by the four persons who are elected to represent S. Savory, Southwark; St. Giles, Cambrewe; St. Lake, Middlesex; and St. Botolph, Bishopsgate, to hold office for seven years; and the remaining eleven to be appointed by the Court of Chancery, without any other restriction than that one must be resident in the parish. They are to be an upper and a lower master of the schools, a resident chaplain, and an organist for the chapel, which is to be maintained as a place of worship for Dulwich. The net income of the college is to be divided into four equal parts; three to be devoted to the maintenance and education of the scholars, and the fourth to the support of aged men and women, at present (1856) not to exceed twenty-four, and to be chosen in equal proportions from the four parishes above named.

Dulwich College. The reconstruction and preservation of the picture gallery. If a surplus should arise from this fund, it is to be applied in providing instructions in drawing and designing for such of the boys in the two schools as evince an inclination and capability for their acquisition.
DUM-CANE. [Caldium, S.]
DUMBLANE. [Pernishie.
DUNDAS. [Canada, S.]
DUNMANWAY. Cork, Ireland, a market-town and the seat of the Potou, of its beneficent siting on the river Bandon near its mouth, in 51° 43' N. lat., 7° 50' W. long., distant 33 miles S.W. from Cork, 190 miles S.W. from Dublin. The population in 1851 was 2222. Dunmanway Poor-Law Union comprises 15 electoral divisions, with an area of 245,625 acres.

The town is situated on level ground almost entirely surrounded by lofty and rugged hills. The greater part of the town was built by Sir Richard Fox, who also obtained for it a charter as a market-town. There are two churches for Episcopalians, a Roman Catholic chapel, and a district Bridewell. A Charter school was endowed by Sir Richard Fox. The market is held weekly; fairs are held in May, July, September, and October.

DUNDEE. [Bannockburn.]
DUNSTER. [Somestonshire.]
DUPERRÉ, VICTOR GUY, a baron of the empire and a French admiral, was born at La Rochelle on the 20th of Febriary, 1775. He commenced his maritime career in the merchant navy at the age of 16, and entered the merchant service. He was later commissioned in the navy and served on a number of ships, including the frigate La Brise. In 1803, he was wounded in the Battle of Trafalgar.

After the revolution of July 1830, Dupont de l'Évre became a commissioner of the law in the provisional government in his own department, and soon after, yielding to the entreaties of Latife, he accepted the office of Minister of Justice; but his principles and want of flexibility were suited neither to his colleagues nor to the government. He resigned his portfolio on the 27th of December, 1830, and resumed his place in the ranks of the opposition. After the fall of Louis Philippe in February 1848, Dupont de l'Évre became, as much against his will, a member of the Provisional government. He died in 1855, at the age of eighty-eight, a firm but by no means a violent republican, he was generally respected as a consistent and honest politician.

DUTENS, JOSEPH-MICHEL, son of Michel-François, was born in the Loire, and at the age of seventeen entered under the École des Ponts et Chaussées, and at twenty-two years of age left it with the brevet of engineer. In 1800 he printed his first work at Evreux, "Des Moyens de naturaliser l'Instruction et la Doctrine," and in the same year published a topographical description of the arrondissement of Louviers, in the department of Èvre. In 1804 he gave to the world his first work on political economy, an analytical exposition of its fundamental principles. In 1814, he was employed by the government to travel in England in order to obtain knowledge of the canal system there, and he extended his labours to all the great commercial works of the country, the results of which were published at Paris in 1819 in "Memoirs on the Public Works of the Canal System of England." The first is devoted to engineering, describing the canals, the works of art employed in their construction, the cost of making, the expense of maintaining, and the system of working; the second is principally to develop the mode of conveyance of water to the country, and the third is devoted to a country where the energies of association are in almost all cases employed instead of the intervention of the government. "Desirous of enabling his country to profit by his studies in England, Dutens published in 1825, 'Notes sur le Navigation de France,' in which he gives a detailed description of the geographical features of France, and an account of its rivers and canals; with an analysis of the agricultural and industrial products of France, showing their values if made available by a net-work of canals, sketching a scheme of what should be the principal branches, and discussing the financial condition which would ensure its success. In 1835 Dutens published his greatest work, the 'Philosophy of Political Economy; or a New Exposition of the Principles of this Science.' In this treatise, Dutens sets forth his ideas with considerable modifications of his previous work, and occasioned much opposition from the economists of the school of Adam Smith. Blanqui says, "It is only a new edition of the previous work, but otherwise it is a complete work in respect to commercial freedom and duties." The severe criticisms occasioned M. Dutens to publish in 1837 a defence of his work, and a second in 1839; and the contest was still going on when the Académie des Sciences elected him a member of their body. He then published in 1843 and 1845, 'Essai comparatif sur la formation et la distribution du Revenu de la France en 1815 et 1835,' a work which contains the best statistical resumed of the productive riches of France, and has received and deserves high praise. In his last issued work, 'Des pretendues erreurs dans les comptes, un jugement des modernes économistes, seraient tombés les anciens économistes relativement au principe de la richesse nationale,' in which he defends the theory of Quesnay, saying, that the rich come from the poor, that a nation does not constitute the wealth of a country, but that this advantage is only due to agriculture. M. Dutens died in 1848. (Neuvelle Biographie Générale.)

DUTROCHET, RENE-JOACHIM-HENRI, a distinguished French botanist and natural philosopher. He was born at the Château de Néon, Poitou, on the 14th of November 1776, and died at Paris on the 4th of February 1847. He contributed to science the discovery of the emigrated, and whose property was confiscated. Young Dutrochet in 1796 entered as a private the military service, but afterwards deserted. In 1803 he commenced at Paris the study of medicine. He made a brilliant career as a student, was received at the College of France in 1815, and was presented to Joseph Bonaparte, king of Spain. He became principal physician to the Hospital of Burgos, which was then devastated by typhus. He displayed here great energy and
skill. In 1820 he returned to France, and gave himself up to the study of those natural sciences for which his medical education fitted him. The tendency of Dutochet's mind was to develop the laws which regulated the existence of organic beings, and many of his researches have had a permanent influence on the development of the departments of science to which they relate. His name is best known to physiologists from his researches on the passages of fluids through animal and vegetable membranes. The laws which he observed to regulate these phenomena he applied to the explanation of the functions of absorption and excretion in the animal and vegetable body. The passage of a fluid from without inwards he called "exosmosis," and the passage from within outwards "endosmosis." His views on this subject were published in a work which appeared both in London and Paris in 1828, with the title "Nouvelles recherches sur l'Endosmos et l'Exosmos, suivies de l'application expérimentale de ces actions physiques à la solution du problème de l'irritabilité végétale et à la détermination de la cause de l'ascension des lîges, de la descente des racines." The phenomena comprehended under the terms endosmos and exosmos were rightly described by Dutochet, but he was hasty in tracing their cause to electricity, and failed to see that they were parts of a much more general set of phenomena than he had described. His other papers are very numerous, and were on a variety of subjects not immediately related. Thus we find his inquiries embraced amongst other things the following subjects: a New Theory of Voice; a New Theory of Harmony; on the Family of Wheel-Animalcules; History of the Egg of the Bird; on the Envelopes of the Foetus; Researches on the Metamorphosis of the Alimentary Canal in Insects; on the Structure and Regeneration of Feathers; on the Height of the Meteor which projected Aerolites at Charbonville in 1810; on the Growth of the Introduction of Plants; and on the Special Directions taken by certain parts of the Plants. The results of all his labours and a connected view of the subjects to which he devoted his attention, he gave in a volume entitled "Mémoires pour servir à l'Histoire Anatomique et Physiologique des Végétaux et des Animaux."

DUVERNOY, GÉORGES-LOUIS, a distinguished anatomist and zoologist. He was born at Montpellier, then a dependency of the duky of Württemberg, now an arrondissement in the department of Doubs in France, on the 6th of August, 1777, and died at Paris on the 1st of March, 1855. His father practised as a physician at Montpellier, and he was brought up to the same profession. He commenced his studies at Stuttgart in 1792, but the princely pittance of Montpellier having been ceded to the French in 1793, he was compelled to finish his studies at Strasburg. He subsequently went to Paris, where he graduated in 1801. In 1802 he was associated with M. C. Dumeril in reporting the lectures of Georges Cuvier, then in the zenith of his reputation. The "Lécons d'Anatomie comparée" were concluded and published in 1806. On the conclusion of this labours he married, and, as natural science afforded him little hope of support for a family, he retired to his native town to practise his profession. In 1809 he was recalled to Paris, and named by De Fontanes joint professor of zoology in the faculty of science. Again, however, he returned to practise his profession in Montpellier, and for nearly twenty years this distinguished zoologist pursued his harassing and laborious duties. In 1837 the chair of natural history in the faculty of science in Strasbourg was offered him; this he accepted; and from this time to his death we find him pursuing with unwearied industry zoological researches. In 1837 he was offered the chair of natural history in the College of France, vacated by the death of his great master, Cuvier. This chair he accepted, and held till 1850, when the death of his emperor having created a vacancy in the chair of comparative anatomy he was appointed to it, and held it for four years. Duvernoy's contributions to zoological science are extremely numerous. In his writings and lectures he was more remarkable for the accuracy and extent of his knowledge than for the novelty and originality of his views. He was an industrious compiler, and was an extensive contributor to the "Dictionnaire des Sciences Naturelles," and also to the "Dictionnaire Universelle d'Histoire Naturelle."

DYNASTES, a genus of Coleopterous Insects belonging to the section Pentacera, sub-section Lamellicornes, and family Dynastidae of M'Leay. The species have the body very large and thick, the outer edge of the jaws incised or toothed, and the lower jaws conoese and toothed. The genus Dynastes embraces the largest and most robust forms of the insect kingdom. They are nevertheless quite harmless. None of the species are found in this country, and only one in France. The largest forms are found in the tropical parts of India and South America. The habits of these insects are much the same wherever they found. They bury themselves by day in holes in the ground, or in the decaying trunks of trees. At night they are seen flying about the trees. The females are more numerous than the males, and do not go out of the holes which give the males so remarkable an appearance. The more remarkable species of this genus are the Elephant and Hercules Beetles. The latter is of a glossy black colour. In the males the thorax is developed into a thick and curved horn, which is bent downwards at the tip, and a similar horn projects from below which points upwards, so as to come in contact with the former. The entire length of this be-tle is 6 inches.

DYSART. [Fifeshire.]

DYSCLASTE, a Mineral consisting of hydrous silicate of lime. It occurs in white fibrous masses, consisting of delicate fibres of a whitish or yellowish or bluish colour. It has a hardness of 4½, and a specific gravity of from 2·88 to 2·96. It is easily gelatinised in hydrochloric acid. It is found in the trap of the Faroe Islands. A variety called Oelinite is from Greenland.

DYSDEMA, a genus of Spiders. The species have 6 eyes, placed in a curve resembling a horse-shoe open in front; the mouth-claws very large, and produced in front; the maxille small, long, and dilated at the place of insertion of the palpi. The type of the genus is D. erythrina, which is an uncommon species in Great Britain. It is mostly found under stones.

DYSODIL. [Coal. S. 2.]

DYSLOUTE. [Mineralogy. S. 1.]
such schemes as should appear to them to be best adapted for carrying those recommendations into effect; the Crown being empowered to make orders ratifying such schemes, having the full force of law. The statute above mentioned was passed in consequence; and under its provisions a great many beneficial measures were taken and are now in operation. The recommendations contained in the four reports of the original commissioners have also been carried out, with certain modifications and amendments, to which the sanction of Parliament (as well as the Crown) was necessary in some cases. 1 & 2 Vict. cc. 30, 106, 108; 2 & 3 Vict. cc. 99, 102 & 4 & 5 Vict. c. 39; 6 & 7 Vict. c. 77; 10 & 11 Vict. cc. 98, 103; 13 & 14 Vict. c. 41; 16 & 17 Vict. c. 50). The chief features of the alterations thus effected are the equalisation of the territorial extent of the dioceses, the creation of the new sees of Ripon and Manchester, and the union of the sees of Gloucester and Bristol. The revenues of the sees have also been equalised, by augmenting the income of the smaller out of the revenues of the larger. Cathedral and collegiate bodies have also been regulated. The powers and constitution of the Ecclesiastical Commissioners have been amended by the stat. 3 & 4 Vict. c. 113, s. 78; and by the appointment of Church Estates Commissioners, who are the Powers of the Office managing the establishment was regarded as a model for the excellence of its arrangements. M. Ebelmen was a member of the commission sent by the French government in 1851 to the Great Exhibition, London. In the beginning of March 1852 M. Ebelmen was named engineer-in-chief of the mines, but he survived the appointment only a few days, dying on the 31st of March, 1852, in his thirty-eighth year.

Ebelmen was regarded with great hope for his combination of sound and minute scientific knowledge with practical administrative ability, and extortive powers of generalisation; and his early death was generally regretted. He contributed a great many papers to the Annales des Mines, the Annales de Physique et de Chimie, and the Bulletins de l'Académie des Sciences. Among the more important were some upon the composition of coal-gas, and its employment in metallic manufactures; and several upon the composition of rocks, the artificial reproduction of mine ashes, c., of which we may mention—Sur les Produits de la Décomposition des espèces minérales, la famille des Silicates, 1845; Sur une Nouvelle Méthode pour obtenir des Combinations Cristallisées par la voie sèche, et sur ses applications à la reproduction des espèces Minérales, 1847; Sur la Décomposition des Roches, 1848, and particularly Sur les Alterations des Roches stratifiées sous l'influence des agents atmosphériques et des eaux d'infiltration, 1851. The more important of his Mémoires have been collected and published under the care of M. Salvetat with the title of Recueil des Travaux Scientifiques de M. Ebelmen, 2 vols. 8vo, 1855. (M. Cheveux, Notice sur M. Ebelmen; Nouvelle Biographie Générale.)

ECCLESIASTICAL COURTS. The Ecclesiastical Commissioners are a body corporate, created by the statute 6 & 7 Will. IV. c. 77, for certain purposes and with certain powers therein named. The great extent and income of the dioceses of England and Wales, in the duties and receipts of the cathedral and collegiate bodies, and in the extent of parishes and the annual value of the benefices of the Church of England, after long and angry comments gave rise in 1850 to the issue of two commissions, directing the persons named therein to consider the state of the dioceses with reference to the amount of their revenues, and the more equal distribution of episcopal duties, and of the several cathedral and collegiate churches, with a view to the suggestion such as appears necessary to them conducive to the efficiency of the Established Church; and further, to devise the best mode of providing for the cure of souls with special reference to the residence of the clergy on their respective benefices. These commissions met in 1851, recommending various alterations, and the appointment of permanent commissioners, for the purpose of preparing and laying before the sovereign in council

Eremurus, the Common Remora, or Suckling-Fish, is found in the Mediterranean Sea, and was known to the Greeks and Romans. Dr. Turton once took a specimen of this species feeding on cod-fish in Swansea Bay. The following is Mr. Yarrell's description of the sucker, subtracting the sucker from the fish:

"The disc of the adhesive apparatus in the specimen now described, with seventeen transverse lamines, was one-third of the whole length of the fish, not including the caudal fin, which was rather equal. The margin is free, flexible, and of considerable breadth, to secure perfect contact with the surface to which it is opposed; the parallel
laminas are represented as only slightly elevated: the degree of adhesion is in proportion to the power used to raise the inner surfaces of the disc in a direction perpendicular to the plane of contact. \* \* \*

The vertical direction of the moveable laminæ is effected by sets of muscles going off obliquely right and left from two elongated bony processes, running along the sides of the moveable carapace, which are divided into two equal sections. The contraction of these muscles acting upon these levers, raises the external edges of the parallel divisions, increasing the area of the vacuum; and it will be observed that, in each section, the moveable tracts, the divisions to which the muscles are attached, are nearer the middle line than the outer edge, by which the chance of interfering with the perfect continuity of the free margin, and thereby destroying the vacuum, is diminished. All the bony laminæ, the outer edge of which is continuous with the corresponding projection of the carapace, are to be considered as nearly gonal at the base, acute. Stamens 10, shorter than the petals, and adnate to the base. Scales 5, short, obtuse. Carpels 5, ending each in a subulate style. The species are succulent shrubs, natives of Mexico. Nectar of the species is found in the arts or medicine, but their buds, young leaves, and showy flowers give them a place in every collection of plants. The genus is closely allied to \textit{Sisyrinchium}, and of many of the species resemble that genus.

\textit{Echinodorus madagascariensis} \textit{[Austrian; Steinheim]}, \textit{Echinodorus gracilis} \textit{[Stebnavian]}, \textit{Echinodorus martii} \textit{[Stebnavian]}, \textit{Echinodorus prolifera} \textit{[Stebnavian; Nitzsch]}.

\textit{Echinodorus pygmaeus} \textit{[Nitzsch; Head-Louis; Paschals, Sorteis, and Bouchard]}. These ecbasic parasitic habits seem to be partaken of by some of the Vertebrate animals, as we find the \textit{Remora} \textit{[Echinus, S. 2]} and other fish attaching themselves to the bodies of animals by an apparatus adapted for the purpose.

\textit{Land animals} are subject to the attacks of various forms of \textit{Ectocoa}, more especially those belonging to the Articulate tribes of animals. The following is a list of the creatures to which man is subject in various parts of the world: \textit{Pulex irritans} \textit{[Nitzsch]}, \textit{Pulex tubercolosa} \textit{[Nitzsch]}, \textit{Pulex camptostoma} \textit{[Sowerby]}, \textit{Pulex camptostoma variegatum} \textit{[Buchheim]}. These \textit{Pulex} are peculiar species on almost every species of animal on which they are found, also with the species of the genera \textit{Pulex} and \textit{Oxina}.

\textit{Echidnus forsteri} \textit{[Nitzsch; Head-Louis; Pascals, Sorteis, and Bouchard]}. These ecbasic parasitic habits seem to be partaken of by some of the Vertebrate animals, as we find the \textit{Remora} \textit{[Echinus, S. 2]} and other fish attaching themselves to the bodies of animals by an apparatus adapted for the purpose.

productions. The first was a series of "Essays on Practical Education," published in 1785; and "Early Lessons," which was continued by him and his daughter; the "Parent's Assistant" was also a joint production, as was the "Essay on Irish Bulls," published in 1803. But Miss Edgeworth's fame rests upon her novels, which were produced without assistance, and which gained for her the benefit of her father's revision while he was living. The series commenced with "Castle Rackrent," published in 1801, and closed in 1834 with "Helen." In the interval there appeared "Moral Tales," "The Prince," "The Model," "Popular Tales," "Tales of Fashionable Life," "Peregrine," "Fizlark," "Harrington," and "Ormond," with some minor tales. Her last production was "Orlando," a children's tale, published by the Murray, Chambers in 1847.

Miss Edgeworth's fame published some years ago in a collected series. The manner which they describe, especially those of fashionable life, belong in some degree to a past generation. But her delineations of character, more particularly of Irish character, are so true to nature, and there is such a vein of quiet humour and practical good sense running through them all, that amidst the more exciting plots and strong situations of the novels of our own time, the more important may be referred to as worthy of a lasting place in our literature.

Miss Edgeworth passed a quiet but useful life with her family; she maintained an extensive correspondence with many friends and literary acquaintances, and at length died March 21, 1849, at the venerable age of 83.

EEO. [REPRODUCTION, S.]

EICHORN, CARL FRIEDRICH, son of Johann Gottfried Eichhorn, obtained considerable celebrity as a able and learned jurist. He was born at Jena on the 29th of November 1751. After passing through the usual course of academic and legal studies, he was named in 1780 Privatdozent at Frankfurt, in 1781. In 1811 he removed to Berlin, and in 1817 to Göttingen, where he held each place holding the same chair as at Frankfurt. Ill-health however compelled him in 1826 to resign, and to retire to an estate he possessed near Tübingen. Having somewhat recovered, he was in 1831 again summoned to Berlin, and along with his professorship he received an appointment in the ministry of foreign affairs. At length in 1833 he resigned his professorship, and devoted himself entirely to his official duties and to writing. About this time he was made a member of the cabinet, and of the commission of legislation. He died in July 1854.

Carl Eichhorn was one of the most erudite exponents of the ancient Germanic law, of its origin, its growth, and its various modifications. A fellow-labourer of Savigny, though taking a somewhat different branch of the subject as the main object of his investigations, and as holding the chair of German law for so many years, Eichhorn exercised an important influence on the study of law in Prussia. His principal writings are—Deutsche Staats-und Rechts-geschichte, 4 vols. 8vo. Göttingen, 1806-18, which work has passed through eight editions; Grundriss des Kirchenrechts der Katholischen und Evangelischen Religionspartei in Deutschland, 2 vols. 8vo. Göttingen, 1815-16; and Einleitung in das Deutsche Privatrecht, mit Einschluss des Lehrenrechts. In conjunction with Savigny and Goschen he also carried on the Zeitschrift für geschichtliche Rechts-wissenschaft, Berlin, 1815-1848.

EIEF, wild high region in the Prussian Rhein-Provinz, extends along the left bank of the Rhine between Bonn and Coblenz. Its proper geographical boundaries are the Rhine on the east, which divides it from the Westerwald; the deep valley of the Moselle on the south, which separates it from the plain; the Ardennes hills, and the Moselle on the west; and the great flat plain of the Lower Rhine on the north. The name however, is extended to the sources of the Our and the Roer to the Rhine. At the head of these rivers lies an extensive highland called Pèrens, or Fragen (from the Celtic fanc' for bog)—a dreary waste covered with ferns, mooruses, and reeds, and rising between 1500 and 2000 feet high, with a length of about 16 miles every way, which connects the Eifel with the Ardennen, and offsets of which stretch nearly to the Meuse below Aix-la-Chapelle.

The Eifel is a rugged, desert, and in parts swampy table-land, which extends from 300 to 600 feet above the Rhine. Its slopes are scored in all directions by deep ravines and valleys, which are traversed by tributaries of the three great rivers named above. The flat surface of the table-land, with the exception of some rather extensive forest-tracts, presents a wild and picturesque appearance. On either side there and here rise up abruptly naked crags and basaltic cones of various elevations, some of them richly wooded, with wide-spread layers of ancient lava between. The general composition of the rocks is basalt, with gravel, schistose and slate, but the hills and rocks of sandstone, limestone, rhyolite, rjasins, and glens of the Eifel are in many instances composed of basalt or cappell with it; indeed the Eifel almost everywhere shows traces of violent convulsions and volcanic eruptions at various periods. The remains of volcanoes, cauldron-shaped depressions, tars of circular shape filling up ancient craters and locally called 'Maare,' mineral-springs, lava-streams, columnar basalt, fossil zoophytes and shells, proving submergence under some ancient waters, are among the natural curiosities of this interesting region.

Amongst the highest points in the Eifel the following may be mentioned:—The Hohen-Acht, above Adenau, 3464 feet above the sea; Nürberg, which is also near Adenau, and is crowned with a castle; the castle of Rur, 2801 feet; Keilberg, near the source of the Eif, 2896 feet; Michaelisberg, near Münsiefer, 1680 feet; and the Schneisef, or Snow-Eifel, in the circle of Prüm, in the wildest part of the region, about the Oder, etc.

The Eifel has a length from east to west, between the Rhine and the Our, of about 60 miles. Along the left bank of the Rhine, north of Andernach, it extends for about 30 miles; but in the interior the breadth is in some places less than this. Rivers flow from it in all directions. On the northern slope lies the Minne-Eifel, a small town in the government of Cologne with about 1600 inhabitants, rises the Eiffel, which flows with rapid course down into the low country, and enters the Rhine at Grünlingen; a range of mountains called the Venn lies between these two streams, and below the Eifel the Roer receives on its right bank the Urt, which rises near Blankenheim, and passes Gemünd, a small town in the government of Aachen with about 1000 inhabitants, who manufacture woolen-stuffs, linen, and leather. Not far from the source of the Roer near the Wargrave, another past Malmedy, and throws itself into the Amblève, a feeder of the Ourthe, in the Belgian province of Liège. The Amblève itself rises a little south of the Warg, which it joins a little below Malmedy. Malmedy, a town in the government of Aachen, stands on the Warg, and has about 4000 inhabitants. It is a quaintly-built place; the houses and gardens are all in the Dutch style. The town is famous for its manufacture of sole-leather; there are above fifty tanneries. It also has many metal springs; many regions of woolen-cloth, lace, soap, potash, and glue. Montjoie stands in a marathy country between two high hills on the left bank of the Roer, and has a population of 3000, who manufacture woolen-stuffs, leather, and leather goods. A large, strong, and glosy castle above the town is said to have been erected as a hunting-seat erected here by Charlemagne: it is a fine specimen of a feudal fortress.

On the southern slope flows the Our, which passes Reil and forms below this town the border between the Prussian Prussia and the Dutch province of Limburg to its mouth in the Sure, a feeder of the Meuse. The Sure receives also from the Eiffel the Prüm, which rises in the Ourthe, and which is a branch of the Roer. Above its junction with the Sure the Prüm is joined by the Nette, which rises in the government of Tréves. It is situated to the south of the Schneisef at the foot of a beautifully wooded hill, and has 2100 inhabitants. Its name is taken by corruption from that of the Benedictine Abbey of Ad Pratam, founded here in the 8th century, and in which Pepin, natural son of
192

1300 inhabitants, at the foot of the Hope-Acht. Ahrweiler, is a pretty walled town entered by four gates, and has about 2000 inhabitants, who are chiefly engaged in the growth of timber and in the manufacture of hosiery. There is a castle, and a collegiate church, near the town, and a Benedictine nunnery. The town has a market, and a fair on St. Michael's Day. Ahrweiler is a seat of the bishop of Mainz, and has a beautiful gothic church erected in the 13th century.

The Brohltal, a small feeder of the Rhine, enters that valley about 10 miles north of Mainz, and is a tributary of the Nette and the Ahr. The streams at Brohltal drives a paper-mill and several tress-mills, in which the volcanic tufa, quarried in the neighbourhood, is ground for exp-rt to Holland; the tufa, reduced to dust, is used by the Dutch for making sugar. The river is lined with trees and shrubs, and is a beautiful scene. In the tufa quarries in the valley of the Brohltal, land shells and trunks of trees r-dced to the condition of charcoal, are found imbedded. Mineral waters, resembling Seltzer, are got from springs in the valley of the Br-hl. A little north frequency hover over it. In all Prussia there is a field repaired by Professor Bethmann Hollweg, of Bonn. Sinzig is a small ill-built walled town of about 1800 inhabitants, with an interest in the Rhine church, erected in the beginning of the 13th century; an adjacent chapel contains a natural mummy, which was carried away to Paris when the French extended their frontier to the Rhine, but was restored at the peace. Sinzig occupies the site of the ancient Sentinunc, near which the cross with the inscription 'In hoc Signo Vinces' is found, and which shows the ancient people marching towards Italy against Massenius. The ancient Roman road along the left bank of the Rhine nearly co-inides with the present diligence road between Bonn and Coblenz. Remagen, a small place of 1400 inhabitants, occupies the site of *Rhojugamum*. Roman antiquities have been found here.

About 6 miles inland from the mouth of the Brohltal, is the large and beautiful crater-lake of Laach, or Laacher-See, which is 666 feet above the Rhine, of elliptical shape, 2 miles long and about a mile and a half broad; its depth increases towards the centre where it is 214 feet deep. The lake is hemmed in on all sides by a ridge of hills covered with wood down to the water's edge. It is supposed to occur from a subterranean eruption of volcanic gas, which issues from an opening on the north-east side of the lake; and in a neighbouring pit bodies of birds have been found killed by the noxious vapour, which circumstance has given rise to a popular notion similar to that connected with Avernus in Italy, that no bird can fly over the Laacher-See. The lake is fed by numerous springs beneath its surface, which keep its basin always full. Its waters are clear, deep-blue in colour, very cold, but never freeze; and abound in fish. The chief natural outlet of the lake is a stream which is carried off by an underground emissary nearly a mile long, cut in the 13th century by the Benedictine monks of the newly ruined abbey of Laach, which is a little south-west of the lake. The shores of the lake are covered with orchards and vineyards, pumice, and other useful products. Laach abbey, or Kloster-Laach as it is called, was suppressed at the time of the first French revolution. Part of the old buildings that remain is now converted into a farm-house; the church, a beautiful specimen on a small scale of the round-arched gothic, erected in the early part of the 12th century, has been purchased in order to its preservation by the Prussian government. The gardens of the abbey, the lake, and village of Laach, are favourite places of resort with the inhabitants of Coblenz. Between the lake and the Nette are the famous millstone quarries of Nieder-Mendig which have been worked in the hard porous lava for 2000 years. The lava stream in which these quarries lie is 6 miles long and 3 miles broad. The lava separates into gigantic columns, some of which are left by the quarrymen to sup- port the roof; there are vast caverns in it, probably the result of ancient excavations. At Mayen, a picturesque old town, on the Nette, with about 3000 inhabitants, rises by a castle and small walled mills and gardens. There are several millstone quarries, a paper-mill, tax-yards, and mineral springs. To the geologist, the botanist, and lover of the picturesque, all the southern and eastern part of the Eifel is a region of the most astonishing beauty. Besides the Laacher-See, there is a lake of less than 27 meare, marking as many extinct craters, exist between the Nette and the Ahr.

The climate of the table-land of Eifel is damp, and much colder than that of the plain of the lower Rhine; cold and dampness appear to render it so district as to poor in arable land as the Eifel. The rugged surface of
The region is covered with wild heath or swampy bog, the thin 
esting of the soil not affording nourishment for the roots of 
the trees. Some parts of it however, as before stated, are 
clothed with forests. This is especially the case in the dis-
trics covered with volcanic deposits. The chief species of 
tree timber are beech, oak, and chestnut, and show a great 
quantity of fuel and timber. The valleys and glens are all 
inhabited, and in these the population is gathered into small 
towns, villages, and hamlets, most of which have sprung up 
under the adorning protection of some feudal castle, and a 
few of which are surrounded by ancient monasteries round 
on the rapid slopes along the Ahr valley and towards the Rhine, 
where fruit and tree yielding valuable crops; here every piece 
cultivated land is covered with walnut, apple, pear, or 
cherry trees. The wine of the Artabl is of excellent quality. 

The region of the Eifel is exposed to a phenomenon called 
Weinbruch, or Cloud-Burst, being a sudden discharge of 
water from the upper reaches, which in the season of great 
May strike; trees are rooted up and hurled down by suddenly 
formed torrent; cattle, houses, soil, and crops are swept 
away. A cloud-burst of this description destroyed the greater 
part of the valley of the Eifel.

The principal roads through the region of the Eifel are 
those from Aix-la-Chapelle to Treves, and from Coblenz to 
Bonn; the high road up the left bank of the Moselle from 
Coblenz to Treves, and the new road up the Artabl to 
Treves. The construction of the last mentioned place had 
been bad. The great Roman road made by Agrippa from 
Treves to Cologne traversed the western part of the Eifel. 
Along it were numerous post houses (poststationes) and six 
mansions, serving as military posts and hospitals. 

Vicus, now Bitburg, was one of these mansteins. Zeilrich 
(population 1900), near the Nassau, a feeder of the Erft in 
the plain, at the northern base of the Eifel, was another of 
the mansions, and was called Tolbiacum. The road is still 
in a perfect state at Zelrich. Remains of an aqueduct which 
ran parallel to the road, and along its whole length, to supply 
the stations with water, are still visible at ten or a dozen 
different places between the two cities. The road along 
the left bank of the Rhine, between Remagen and the precipitous 
port of Sankt Goar, is a civil work (reconstructed 281) in 
which every thing that is good has been ill, and is crowned with 
the ruins of an old castle, is cut in the rock. In making this part of the road several Roman 
remains were found. Connected with Rolandseck is the 
circular crater of Bodenberg, which is a quarter of a mile 
across and 100 feet deep; its sides, which are composed of 
tufa and scori, are cultivated. The castle of Godage, 
a town of about 1000 inhabitants, a short distance north of 
Rolandseck, is an interesting object on the road and from 
the Rhine. Between Godage and Bonn, at the north-eastern 
extremity of the Eifel, are the coal and alum mines of 
Friedorf. The coal is of the kind called lignite or fossil 
wood, and has evidently resulted from the subsequence of some 
primal forest; fossil fishes, fresh-water shells, and very 
flakes of bone, have been found in this region. The inhabitants 
are, however, not very numerous, and are very poor; their dress rather 
slowly than neat, and their houses are in general rudebly 
constructed. Iron and lead mines are worked near Gemund. 
The manufactures are unimportant, with the exception of leather 
manufatures, which are somewhat improved. The region of 
the Eifel is a said to be an old German name for the Ardenn, on 
which region the Eifel is in reality a part.

EJECTMENT. The action of ejectment (Ejector) in 
which the plaintiff is the present or former tenant, and the 
plaintiff is in action of ejectment, and is not alone the 
nominal plaintiff. The name Richard Roe the nominal defendant has been abolished, and 
new and simpler mode of proceeding substituted for it.

John Doe's suit was attended with one great disadvantage: 
it could only be followed out during term, so that, if a right 
to lands in Yorkshire accrued on the 1st of June, the person 
entitled would be unable to bring his adversary into court before 
the following November, or in case of a defence, to proceed 
before March in the following year. The fictions on which 
the old mode of proceeding was founded were objectionable, 
and accordingly, when the procedure of the 
Superior Courts of Common Law was reconstructed in the 
year 1852, a new mode of proceeding for the recovery of 
land was created, which has not only the one distin- 
guishing peculiarity of the old action, that in it no question 
can be raised except that of title. 

This new action is commenced by the issue of a writ, 
directed to the persons in possession by name, and to all per-
sons entitled to possession by the persons so named, and to 
all persons claiming by or through such persons; and commands 
the persons to whom it is directed to appear within sixteen days to 
defend the possession of the property claimed; a notice being added, that, in default of ap-
pearance, they will be turned out of possession. This writ is 
served on the tenant in possession, or, in case of a vacant pos-
session, by posting a copy thereof upon the door of the dwell-
ing-house, or other conspicuous part of the property. Every 
tenant served with a writ must give immediate notice thereof 
and appear and demur, or, if unable to appear, to surrender 
the rack rent of the premises held by him. The object of giving 
the landlord notice, is that he may be permitted to defend, 
which he has a right to do, for frequently the tenant has no 
in interest in the premises beyond the temporary possession. 
A trial on demurrer, or at the next convenient time, is fixed to 
defend the possession; for possession has now become the 
very essence of property, twenty years' uninterrupted pos-
session constituting a title good against all the world.

If no appearance is made to the writ, a judgment to 
recover possession of the land claimed; to which he by 
the writ asserts his right. By entering an appearance, the 
tenant, or the landlord, or any other person admitted to de-
defend, denies that right. The parties are then at issue on 
the title to the land, and the next thing is for the tenant 
claimant to prove his alleged right to a jury on the trial, 
which must take place, in all ordinary cases, in the county 
where the property is situated; the proceedings at and after 
the trial being the same as in ordinary actions.

Such is the modern way of trying the title to lands 
and tenements. It is founded on the same principle as the 
ancient writings of assize, being calculated to try the mere posses-
sory title to an estate; and has succeeded to those real 
actions, as being infinitely more convenient for attaining 
the end of justice. It has on the same principle been rendered 
a very easy and expeditious remedy to landlords whose 
tenants are in arrear, or who hold over after their term has 
expired or been determined. The Common Law Procedure 
Act (11 & 12 Vict. c. 26) empowers a landlord to bring a 
right of re-entry in case of non-payment of rent, when 
half a year's rent is due and not sufficient distress is to be 
had, to serve a writ of ejectment on his tenant, or fix 
the same upon some notorious part of the premises, which 
shall be valid, without any formal re-entry or previous deman-
dent. And a recovery in such ejectment is final and conclu-
sive, both in law and equity, unless the rent and all costs 
be paid or tendered within six calendar months afterwards.

The same statute (re-enacted 1839 and 1849 IV. c. 87), enables 
the landlord, on serving a writ of ejectment on a tenant 
holding over after his term has expired or been determined, to 
give him notice that he will be required to give bail (if ordered 
to do so by the court or a judge), conditioned to pay the costs 
and damages, if the claimant be able to recover in the suit. 
A judgment for recovery in this case is a nullity, and is 
not open to appeal, for the premises do not exceed 50L, and no fine 
have been paid, proceed in the County Court (19 & 20 Vict. 
c. 108, ss. 80-86). And if the rent does not exceed 20L., 
and no fine has been paid, he may proceed summarily before the 
justices in its own county (Johnson, 327; Blackstone's

ELASTIC TISSUE. The elements of Elastic Tissue are cylindrical or band-like fibres with dark contours, very minute, and when present in large numbers they exhibit a yellow appearance, and it has been called Yellowness Fibre. The fibres acquire sometimes little cavities in particular spots, which give these fibres a striated appearance, as seen in the giraffe. The elastic tissue is rarely found in large masses, but is very frequently mixed with the regular tissue, either in the fibres of networks of various kinds. The organs into which this tissue enters, and constitutes their special feature, are:—

1. The elastic ligaments, in which the tissue, with only a slight admixture of connective tissues hard, dry vessels and nerves, exists, so to speak, in a pure form. Of these we have examples in the ligamentum subflava of the vertebræ, the ligamentum nuchae, the ligament of the larynx, and the subligamentous ligament.

2. The elastic membranes which appear either in the form of fibrous networks or of fenestrated membranes, and are found in the walls of the vessels, especially in those of the arteries, in the trachea and bronchus, and in the fascia superficialis.

(Manual of Histology, translated by Busk and Huxley for the Sydenham Society.)

ELECTION. The proceedings on the election of knights and burgesses to the Commons House of Parliament have four principal periods: the nomination, the return of the candidates, the poll, and the counting. The whole, as already stated, is of a very minute and complicated nature, and is often more or less, directed to obtaining what is called 'purity of election.' With this view, the elections, alike in counties and boroughs, must now be completed in one day, so that neither time nor opportunity may be allowed of extensively tampering with the voters. The merely formal proceedings are still taken under the original Reform Acts; but the bribery oath can no longer be administered to a voter. In order, however, to restrain bribery, treating, and intimidation, the returning officers are now required annually to appoint election oaths, through whom the voter can account in court; and the election is conducted by the candidates. Stringent provisions have been made for inquiring into charges of corrupt practices, by Committees of the House, sworn to the performance of their duties. Bribery, if proved, involves the disqualification of the elector, and the unseating of the member chosen, if the charge is brought home to him. The candidate is required to appoint his own agents, in writing, so that they may be known; and to send all accounts and a note of all his expenses, to the election auditor; who, when the election is over, pays and publishes the expenses in the local newspapers. It may be added here, however, that both the method of proceeding at elections, and the principles which ought to guide legislation on that subject are at present in a state of transition. The election is a matter of temporary operation and of an experimental character. (Blackstone's Commentaries, Mr. Kerr's edition, vol. 1, p. 168.)

ELECTRIC TELEGRAPHIES. In the previous Supplement a full account of the discovery and of the application of the electric telegraph was given. [Telegraph, Electric.] All that remains now is to complete the account by a statement of its more important improvements, and more especially of the extended transmission of messages by submarine telegraphies, bringing the most distant countries into almost immediate connection.

At the present time almost every important town in Great Britain, with the exception of Inverness in the far north, and Palermo in the south, is furnished with means of telegraphic communication to other towns. As fast as any new railways, whether trunk or branch lines, are opened, so surely is the telegraph new laid down; insomuch that the languages of the two countries, though separated by the length of the line. The exceptions to this rule are so few as scarcely to disturb the simplicity of the rule itself. From Cornhill, from Charing Cross, from the government offices, and from numerous other places in the metropolis, messages are every day transmitted to Aberdeen in one direction, to Liverpool in another, to Dover in a third, to Southampton in a fourth, to Plymouth, to Milford Haven, to Holyhead—indeed, to almost all of our ports, and to nearly every inland town of any commercial pretensions. A system is everywhere acted on that the principal railway stations shall at the same time be telegraph stations, some of the wires being for public use, and the others for railway use. The charges have been reduced, the forwarded, to the great advantage of parties; and the messages now sent are of countless variety—the price of funds, the state of the markets, orders to purchase, the arrival of ships, the receipt of important news, the Queen's speeches, the result of elections, the divisions in Parliament, and the like. In the course of the year while travelling, the state of the weather, the verdict of an important trial, the sending for a doctor, the detection of a thief or murderer, inquiries after health, announcements of births, deaths, and marriages, inquiries after lost luggage—are only some of the thousand open or conditional communications intrusted to the copper wires.

In most parts of England the wires, as from the commencement of the system in this country, are supported on poles at a height of several feet from the ground, in a few cases, such as along the mail-coach road from London to Dover, a subterranean arrangement has been adopted: the wires being enclosed in a wooden trough, and deposited a foot or two beneath the surface of the ground. This arrangement is also adopted in the streets of London, and of other large towns.

An interesting use of the sub-way telegraphy may be here noticed. In proportion as the use of Greenwich time has become familiar on all the English railways, so has it become important to fix in this time some means by which we may make the system of the railway offices to enable all the station-clocks to be regulated thereby. This is one purpose of the new time-ball in the Strand. The Electric Telegraph Company, the South-Eastern Railway Company, and the Greenwich Observatory, have entered into a contract in the establishment of this plan. A subterranean wire has been carried from the Observatory, through Greenwich Park, and across Blackheath to the Lewisham station of the North Kent Railway; thence to the London Bridge station; and thence to the Strand office. The system is such that at the top of this office has been erected a hollow shaft, up the interior of which the electric wire is carried, and a large light ball, capable of moving eight or ten feet vertically, slides easily up and down near the top of the shaft. At ten minutes past one each day the ball is raised nearly to the top of its shaft or spindle; and at five minutes before one it is raised quite to the top. At one o'clock precisely, exactly to a single second, the great or master-clock at Greenwich Observatory puts in action a small metal mechanism which sends an electric shock through the wire to the Strand; the wire at this end is connected with another piece of mechanism, which releases the ball and allows it to fall suddenly. The ball falls upon a kind of piston in an air-cylinder, so arranged that it drives a pointer which runs up and down a scale of feet above the level of the Thames; as it is six feet in diameter, exhibits bright colours, and falls through a considerable space, its descent can be seen for a great distance on all sides; and all who choose to regulate their clocks and water-gauges can do so. This system is such that the electric current should fire off a gun at the same time and place, so that the sound might be heard if the descent of the ball could not be seen.

In the English telegraphs, the wires employed are usually of 1/30 inch diameter, covered by a special coating of zinc, to prevent oxidation. Four miles of such wire weigh about a ton. The supporting posts are about sixty yards apart, with connecting wires of copper, insulated with paper, so that the wire may not touch the wood itself; the connecting pieces themselves being sheltered from rain by a small overhanging roof. At intervals of a quarter of a mile are winding posts, with
apparatus for screwing up the wires to the proper degree of tightness, and joining the several lengths together. The great number of wires which we see along the chief lines of railway are not all necessary for transmitting one message; a single wire will effect this; but many are required to keep up correspondence of different kinds, and with various stations.

The 'needle telegraph,' as it is called, is still the one generally used in this country; that is, one in which, instead of pressing down the keys of a finger-board, the manipulator wrings a greater spring in the lines, and in this way he delineates, by means of certain indices, the relative positions of which indicate letters and words. The action of the machines was sufficiently described in our former article. [TELEGRAPHS, ELECTRIC.] Improvements have been since introduced, but the principle is in its general features the same as that which has been made by the Electric Company. Many patented inventions and machines, to be used subsidiary to the needle-telegraph.

Such as there has been of legislation in England concerning electric telegraphs and their patentees, it bears no comparison with that of the United States, where the system is developed with so much more completeness. The telegraphs principally employed in that country are those of Morse, Bain, and Morice. In 1855, it is chiefly the owners of Mr. Morse's patent rights by whom the legal contest is carried on. In one trial in 1861 the evidence extended over a thousand printed pages; and in several other trials it extended to many hundred pages—containing the opinions of more than one hundred witnesses. Between 1837 and 1849, Professor Morse took out seven patents, under the powers of which many thousand miles of telegraphic wire have been laid down.

Bain and Morse both employ a method which, for familiar illustration, may be characterized as nearly the same; and we will therefore briefly describe Bain's. Let us suppose a message to be sent one hundred miles, from one station to another. The letters of the message are separately transmitted, by means of a key-board or a set of handles; or at least a series of conductors, which are all connected together. At the other end of the wire, a small needle or metallic point has slight reciprocating movements given to it by the impulses; and it presses upon a strip of chemically-prepared paper which slowly moves onward by means of clock-work. At the instant of contact, the paper becomes discoloured by a chemical action between it and the iron; these discolourations appear in the forms of dots and short lines, certain combinations of which are understood to represent the letters of the alphabet. The whole system is thus made up into a message is thus preserved—in a cypher which requires to be translated into English for the use of all except the telegraph officers.

There are many patented systems in England, Germany, and America, exhibiting analogies to those of Bain and Morse. Mr. Rogers, of Baltimore, substitutes a pen for a needle or point, a brass die for a paper strip, and a kind of ink for the chemical preparation in the paper. The pen is dipped in the ink, which imparts a mark to the page. At the other end of the wire, a metallic point has slight reciprocating movements given to it by the impulses; and it presses upon a strip of chemically-prepared paper which slowly moves onward by means of clock-work. At the instant of contact, the paper becomes discoloured by a chemical action between it and the iron; these discolourations appear in the forms of dots and short lines, certain combinations of which are understood to represent the letters of the alphabet. The whole system is thus made up into a message is thus preserved—in a cypher which requires to be translated into English for the use of all except the telegraph officers.

Mr. Bakewell and other inventors in England have put in practice printing telegraphs, in which the letters of the alphabet are stamped upon the paper, instead of being written in ink. These machines are described in a paper read by Mr. House, which is now before the house.

This wire, in four hours, the telegraph is capable of transmitting more words in a minute than either of the other two principal American systems; but to balance it a great deal of time is consumed in adjusting the instrument. There is a fallacy in some of the statements respecting the rapidity of these systems; the swiftness with which messages may be transmitted has been greatly exaggerated. Mr. Bain's 'fast method' enables one thousand letters to be transmitted per minute; but the process of preparing the message requires about as much time as the transmission by the ordinary method. It is said, that in the ordinary every-day working, the American rate of transmission averages from seventy-five to a hundred letters per minute. On one particular day, in the spring of 1845, Bain's line transmitted 800 messages, besides 6000 words of foreign news, from Boston to New York.

Remarkable and valuable as is the degree of rapidity already attained, there are many reasons to wish for still greater facilities in the subject. Some of the principal improvements have been made by various inventors, some of them, in reality, are improvements of the earliest patents, and have been made by the Electric Company. Mr. Bain invented an ingenious machine for punching the holes in the paper. The actual transmission was very rapid; but by the time the punching and the subsequent translation into English were completed, not much time was gained over the ordinary method.

In relation to the wires linking Great Britain with other countries, the submarine principle has been brought very remarkably into operation. Beginning at the north, and working half round the island, we first meet with the Portpatrick and Carrickfergus cables (26 miles) dipping between the Scottish and the Irish Shores. In 1858, a line to Ireland was laid; and in 1861 there was opened a line from Portpatrick to Stranraer and the centre of Scotland; the other through Stranraer to Dumfries and the net-work of British lines. At the other end the cable is connected with the line of the Irish railway through the Irish lines. Without any difficulty a message is sent from London to Ireland via Dumfries without regard to circuitousness of route; for the electric current reckles little of distance. Next comes the line to Dublin, the cable (64 miles), joined at one end to the Welsh and English lines, and the other end to the Irish lines. In the south the Hants and Isle of Wight cable, not very important commercially, but establishing electric communication with her Majesty's marine residence at Osborne; it is connected at Hurst Castle with a land-wire running through Lymington to the Brockenhurst station, and at the other end with a land-wire passing through Yarmouth to Osborne. Further east is the Dover and Calais cable (22 miles), connected at the two ends with the submarine system of the Baltic; and relatively connected with the European wires. All these cables are thicker than that intended for the Atlantic, presently to be described; and all have had occasional mishaps; but taking them collectively, they afford a remarkably curious apparatus, which may be exchanged between Great Britain and all the neighbouring countries. The salt-water, the storm-tossed ocean, have been pretty nearly conquered by the ingenious men engaged in these operations; and now the English public hear with little surprise of messages telegrams (to use a new word concerning which Greek scholars have been carrying on a fierce battle) brought under water as if brought on dry land.

Directing attention next to the continent of Europe, we find telegraphic wires ramifying in all directions. Nations were never more struck with the wonders of the electric telegraph than on the occasion of the death of the Czar Nicolas in 1855. On the 2nd of March the Rial of Clar- rendon announced in the House of Lords that the Czar died at St. Petersburg at one o'clock on that same day. Two distinct messages had been received, one wid Berlin and the Hague, the other wid Berlin and Ostend, both communicating a message telegraphed to Berlin from St. Petersburg, and sent by land and sea over the actual electric cables of the Russian post. The northern wastes of Russia have been brought within the civilising influence of the bit of copper wire, and lines in all directions have been laid, with or without regard to railways. Nearly all the chief cities in Europe are now linked together. Cir-
Bohemia, Austria, and Istria, the connection is nevertheless complete; and telegrams are twice a-month transmitted to us relating to Indian affairs, brought to Trieste from Alexandria. Italy, in railways and in telegraph, is in areas of Austria and Spain is lower on the list than Italy. Turkey, to the great astonishment of many of the Osmanlis, has been made a sharer in the fast-going, high-pressure operations of the age: she possesses an electric telegraph, extending from the Black Sea to Constantinople, by which news from the seaport could now be flashed from London to the seat of the Ottoman empire. During the Russo-Turkish war, an electric cable 300 miles in length was sunk in the Black Sea from Varna in Bulgaria to Karsisch in the Crimea, there to be available to the Russian engineers engaged in the subsequent siege of Sebastopol: it was one of the many contributions of peaceful industry to dread war. The Czar Alexander and the Sultan Abdü-l-Medjid, now that hostilities have ceased between them, wish, if so disposed, by specially telegraph, for there is an uninterrupted copper wire extending all the way from the capital of the one to that of the other, passing in its route through Berlin, Dresden, and Vienna. Nay, if business or pleasure suggested it, a dozen emperors and kings, seated in a dozen capitals, might exchange greetings all in one day, or perhaps in an hour or two, and might make a score of petty princes sharers in the achievement.

Naumov to the routes for traversing the Mediterranean by telegraph. The two islands of Corsica and Sardinia, belonging to two energetic sovereigns, have been connected by telegraph with the French and Sardinian continental dominions: land-wires on the islands themselves, and submarine cables from Corsica to Genoa and Sardinia to France. This being done, the grand question arose—how to span the broad Mediterranean, so as to connect Europe with regions far beyond. Glancing at a map, we see that the southern end of Sardinia makes a tolerably near approach to the northern coast of Africa, at some point in the palaic of Tunis. We also see that Sicily, Malta, the Ionian islands, and Candia, form spots of dry land which might be used as resting places for separate lengths of submarine cable, should commercial and other reasons justify the adoption of such places. A line of 750 miles, laid down by the Sardinian government, has been formed, which has laid down a submarine cable on the first of these two routes. From Sardinia to Malta, and from Malta to Corfu, it was found that the water is of much less depth than in the line of route from Sardinia to Africa; and as these islands lie in the way towards the Levant and Egypt, an enterprise was commenced to connect the various islands by a chain, of telegraphic links. The whole of this line, 450 miles from Sardinia to Malta, and 350 miles from Malta to Corfu, was completed last year; and the part of the Austrian government to extend their land-telegraph from Trieste to Ragusa, to lay down a submarine cable from Ragusa to Corfu, there to join the line just described, was also in contemplation, with a view to stopping at no intermediate island. The Mediterranean cables, actual or proposed, may thus be classified in four groups: from Spezia in the Genoese State to Cagliari in Sardinia, promoted and supported by the Sardinian government, from Cagliari to the African, by the British government; from Cagliari to Malta and Corfu, by the English government; and from Trieste to Corfu and Alexandria, by the Austrian government.

A few words must be said concerning the rival projects for connecting Asia with Europe by telegraph. Supposing all the attempts in the Mediterranean to succeed (and succeed they probably will after a time), there will be one termine of electro-communication on the north coast of Africa, another at Corfu, and a third at Constantinople; and the question then arises—how best to apply the system to Asia. Two projects have been competing for public favour during 1857 and 1858—the Red Sea and the Euphrates routes. The first of these comprises a submerged cable along the Red Sea, to be laid down at Aden, whereby a land wire or a submarine cable to India; while the other starts from Syria or from Asia Minor, and follows the valley of the Euphrates through Mesopotamia to the Persian Gulf and the Indian Ocean. The history of the latter is prolonged, whenever convenient, to India. The promoters of the Red Sea cable estimate its merits somewhat in the following way. There would be a land line of 450 miles from Alexandria to Suez; and then a submerged cable of 4800 miles from Suez to Kurrachee in India in two lengths, joined at Aden as a resting-point.

Between Suez and Aden there would be three resting-points on land, at Cossir, Juddah, and Camaran; while there would be three others between Aden and Kurrachee, at Ras Shurmah, the Kooria Mooria Islands (now a British possession) and Ras el Had, in the Imman of Muscat’s territory. The promoters say that 700,000l. in money, and one year in time, would complete this great enterprise; but that if the Indian Ocean section, from Aden to Kurrachee, were suspended for want of money, they could lay down a submarine cable of 6000 miles, at a cost of 300,000l. in money, and eight months of time, would suffice to establish a telegraph from Alexandria to Aden. The promoters urge that they have obtained the necessary firman from the Turkish and Egyptian Governments; that a cable from Alexandria to Kurrachee is freed from the duties of ministerial politics; that plans are already made by other parties to connect Alexandria with Europe by a cable from Austrian and Sardinian ports; and that, even should these projects fail, the Red Sea Telegraph Company would undertake to lay down a cable of 800 miles from Alexandria to Constantinople—in either case ensuring complete telegraphic communication from London to India. On the other hand, the Euphrates Company proposes a land-wire of 1200 miles, starting from Constantinople, stretching south-westward across Asia Minor, and thence to the Euphrates, or to Baghdad on the Tigris; then a river-cable to the Persian Gulf, and lastly, a submarine cable to Kurrachee at the mouth of the Indus—the two cables together being about 1600 miles, or 2800 miles in all. The estimated cost is 400,000l., and the time of completion six or eight months.

Having thus noticed the various projects for establishing electric communication between Europe and India, we come to a few words concerning what has been effected in India. In 1852 Dr. O’Shaughnessy, after a series of preliminary experiments, was empowered by the East India Company to establish a magnificent series of telegraphs in that country. During the remainder of the year he constructed and employed in procuring from England the immense quantity of material required, and all the working apparatus. He commenced the actual construction shortly before the end of the year just named, and on the 24th of March, 1854, he sent a telegram from Madras to Sh.WriteByte(187,187,187)ar, stating that he had established the whole trunk line from Calcutta through Agra, Delhi, and Lahore, to Attock on the Indus; a branch from Agra to Bombay; and another from Bombay to Madras—the whole extending to 3050 miles, and including 41 offices or telegraph stations. During the year 1855,3800 miles of trunk line were extended from Sh鲃ar to Peshawur on the Afghan frontier, from Rangoon to Meeaday on the Burmese frontier, and from Bangalore to Ootacamund—extending the total length to 4000 miles. The whole system was completed in 1856, and, although interrupted by war, other lines were executed, raising the length to above 5000 miles. Throughout Central India the engineer was opposed by enormous difficulties; there was no metalled road; there were few bridges; the jungles are in many places deadly for at least half the year; and there was no police for the protection of the wires. More than seventy principal rivers have been crossed, some by cables, others by wires extended between masts; the Toonbuddra crossing was two miles wide, and that of the Soone more than three miles.

The telegraphs of the East India Company begin at Madras; the telegraph there is more substantial than any known in Europe or America; for 174 miles the wire is borne on masonry pillars capped with granite; while for 332 miles it is supported on superb granite slabs, each 16 feet high. The whole expense has, nevertheless, been kept within 50l. per mile.

Viewing the state of telegraphy on the other side of the Atlantic, we come to that which almost baffles calculation. The telegraph system is the same in all directions, but the telegraphic wires have far outstripped them in length. The Americans, having millions of acres that belong to no one, or that are of very slight value, set up their telegraphic poles and stretch their wires in spots where no man could use them for the purpose of conveying intelligence through forests, over rivers, across prairies, over mountains—nothing stops them, and as the engineers and companies care little about strength or symmetry, the telegraphs are set up with wonderful cheapness. cheapness of telegraph lead
Atlantic Telegraph.—The effort to establish a telegraphic communication between England and the United States so far transcends every previous undertaking of the kind that we deem it advisable to describe the operations in some detail. A paper has enabled us to operate with which we have been favoured by a gentleman intimately acquainted with the whole course of the proceedings. A company having been formed in 1856 for the purpose of constructing an Atlantic Telegraph, the Governments of Great Britain and the United States agreed not only to pay each to the Company a subsidy of 10,000 l. a year, for 25 years, but to assist the undertaking, by furnishing the men and ships which should be required in the laying of the cable. The preparation and perfection of the electrical details of the work were left in the hands of Mr. Wildman Whitehouse. Three gentlemen who had practical experience in the work of marine telegraphy, Mr. Canning, who submerged the Newfoundland cable, Mr. Woodhouse, who connected Balaklava and Varna during the Russian war, and Mr. F. C. Webb, who had the charge of the line between Orfordness and the Hague, were associated with Mr. C. Bright, in preparing the engineering appliances for the submersion of the cable, the manufacture of the paying out machinery being intrusted to Mr. Henry Clifford, under the superintendence of Mr. C. Bright. A company which had been incorporated by the legislation of 1851 could little further assist in the submersion of the "New York, Newfoundland, and London Telegraph Company," transferred all their rights to the Atlantic Company, securing to them the exclusive privilege of landing a cable upon the Newfoundland shores during fifty years, and upon the coasts of Nova Scotia during twenty-five years. Patent rights in apparatus which would be required in working the line, were also secured to the company by Messrs. Whitehouse and Bright. Never had more extraordinary preparations leading to the undertaking were entered upon. It was deemed very important that the capability of transmitting an electrical current through a coated conducting wire as long as the Atlantic is wide, should be put to the test of direct experiments. Mr. Whitehouse had already availed himself of several opportunities furnished by the chance of lengths of cable being under construction, which had separate wires imbedded in the insulating gutta percha mass; the wires being so joined at their extremities upon the occasion of the experiments as to form continuous conducting circuits, the whole being operated at Greenwich with an extent of 1146 miles. In the following year, with the co-operation of the Magnetic Telegraph Company, arrangements were made for the crowning trial in the per- sons of Mr. Whitehouse and a Mr. C. Baddeley. The results were so satisfactory, that a permanent connection, and the time. The wires of this company extended under ground, and through the sea, from London through Dumfries to Dublin, along a course of 690 miles. They are also so numerous, and so connected with a wide system of ramifications, that, upon need, a length of some six thousand miles can be formed. Upon a pre-determined night, that of the 9th of October, ten gutta percha-covered insulated wires, each more than 200 miles long, were connected into a continuous circuit of more than 1000 miles. The conductor wires were fastened to the building at the offices of the company in Old Broad Street, London. A pair of Mr. Whitehouse's induction-coils were used to excite the wires, and the current was made to act through one of Professor Morse's ordinary recording instruments. Signals were distinctly telegraphed through the two thousand miles of wire at the rate of 310,241, and 270 per minute! This result was deemed eminently successful, and as proving beyond all fair ground of question, that the transmission of an electric signal through a coated wire laid across the bed of the Atlantic is possible, Mr. Whitehouse's late experiments for though the greater part of the cable employed in this experiment was subterranean rather than subaqueous, it is now well known to the initiates in these matters, that the two cases are, as nearly as possible, identical in all their essential characteristics and properties. During the preparation for the construction of the Atlantic cables, and indeed even more available during its manufacture, Mr. Whitehouse was engaged in putting several important matters concerning the rationale of electrical action to the rigid questioning of experiment. Many of the results which were elicited through these investigations are of surpassing interest, and require to be alluded to as contributing notable pages to the pages of the history of electrical science. Foremost among the labours of the experimentalist, however, necessarily stood the completion of his instrumental means of research. He very soon found that the apparatus which had been previously in use as measures of electrical force and current would entirely fail to answer the examinations he had undertaken upon. He consequently set himself to work seriously to remedy the defect. The usual method whereby the force of an electrical current had been employed was to suspend a freely suspended magnetic needle near to, or within, a many-spirited coil of the conducting wire. The degree of the magnetic needle's deflection from its position of equilibrium, was then held to give the acting force of the current. This answered very well so long as continuous currents of moderate intensity were under examination. When, however, the experimentalist came to deal with sudden and interrupted currents of high intensity, such as the streams which the Atlantic telegraphy have to deal with, no steady deflection could be produced. The needle jerked fitfully and violently backwards and forwards with so much caprice that it defied the adroitness of the most skilful observer to get any intelligible indication of force out of its position of equilibrium. This drawback led Mr. Whitehouse to dispense altogether in his investigations with the triffling and unstable needle, and to call in his assistance, in its stead, that power which is fixed and stable beyond all other forces that are known to man. He resolved that he would substitute as much as possible of the same for the needle, and that he would put its strength in the scale, make terrestrial gravity determine the amount, and send in a record of the same in grams. The ingenious piece of apparatus whereby a combined measurement and registration of the electromotive action, Mr. Whitehouse named, when he had perfected the mechanical details of its construction, his Magneto-Electrometer. Mr. Whitehouse's instrument for measuring the force of electrical currents consists of a delicate steel-yard suspended at each side by springs similar to those which are used for the support of the pendulums of clocks. The short end of the steel-yard is armed with a bar of soft iron, and at a short distance beneath this is placed another bar of soft iron, surrounded by a coil of fine wire carrying a current of copper wire, and therefore capable of being converted into a magnet whenever a current of electricity is flowing through the coil. The strength of the artificially formed magnet depends on the power of the coil, and the weight of the steel-yard; and consequently a greater or less weight can be tilted up on the long arm of the steel-yard accordingly as the short arm is more or less powerfully attracted. By shifting weights along the steel-yard, by changing these weights for others of different magnitude, and by varying the distance of the current from the artificially magnetised bar, so wide a range of mechanical adjustment is commanded that degrees of attraction can be accurately estimated from these capable of tilting up but a small fractional part of a grain, to those which can lift many thousands of grains. Mr. Whitehouse also prepared an instrument which enabled him to compare the velocity of transmission of different currents of electricity through the same wire, or of the same current through different wires. The instrument consists of a pendulum, beating true seconds, connected with a voltaic battery, and of a ribbon of chemically prepared paper unrolled from a drum by a train of clock-work. The pendulum hangs upon a pivot, which is vertically one of the poles of the voltaic battery, and its rod is prolonged upwards into a sort of crest, which comes into contact with a spring right and left, as it swings to and fro. The springs, when not touched by the pendulum, press upon a metallic plate, which is itself set free from the battery. The crest of the pendulum lifts the spring, which it touches for the time, from the pillar. When it lifts the right spring it sends an electrical current out through it and any conducting wire placed in communication, and back through the left spring, which is connected to the pillar of the battery. When it lifts the left spring exactly the opposite proceeding occurs. The wire which forms the circuit, and which is supposed to be a lengthened one, is curled into a coil near to either extremity, and into each of these coils a bar of soft iron is inserted. These bars become temporary
magnets whenever a current of electricity is passing through the coils, but the precise polarity of either extremity depends on the direction of the currents. The extremity, which is a north pole when the current issues from the battery through the right spring of the pendulum apparatus, becomes a south pole when the current issues through the left spring. Near to each temporary magnet is placed a permanent magnet, which is arranged to strike the linear style pressed down on the ribbon of paper, so that a visible trace is left upon its surface. When the magnets lie in another direction, they turn the currents of the local batteries off, and cause the pen to cease to print. Therefore it is the pendulum which reverses the direction of the primary current in the long wire, and so the positions of the temporary magnets, a trace is printed on the temporary ribbon of paper, each alternate second, as the ribbon is drawn along, and an intermediate interval is left. But there are two batteries printing, one at each extremity of the wire, if any appreciable time be occupied by the passage of the current along its extent, and if the two batteries are made to record, side by side, upon the same ribbon, the distance between the two respective points in the second-long trace will be an estimated by comparison with the second's-long trace, will afford a measure of the time. In this way the length of time the electrical current takes to run through the wire from one printing instrument to the other, can be determined within the extreme limits of an accuracy of 1 1000 of a second, and so the linear representative of a second. It does not at all matter what the speed is with which the paper ribbon is unwound beneath the printing styles, because the estimate is always a relative between what each instant to a particular length to a particular pace, is made by the beat of the pendulum. When the velocity of transmission in any special wire is to be examined, the apparatus is set to work, and a somewhat lengthened series of observations is printed off. This is then narrowly scrutinised, with a view to the length of the heavenly days, and the mean of all the more trustworthy ones is noted as the result to be adopted.

One of the most important deductions arrived at through the instrumentality of this ingenious apparatus, was the fact that voltaic electricity is capable of producing greater mechanical effects at the extremity of any given wire, than the induced electro-magnetic current, but performs its journey through a long course with inferior speed to its weaker companion. It is in order, however, to state in this connection the heaviest agent proved to be by no means the most fleet and agile one. Seventy-two pairs of sixteen-inch sand-battery plates lifted 1400 grains on the steel yard of the magneto-electrometer at the end of 600 miles wire, but the current of the voltaic wire only raised 14 grains, in the same space, as the distance. Two large electro-magnetic induction coils, excited by a Smee's battery of ten pairs of one hundred square-inch plates, sent forth a current which lifted 745 grains at the end of the same wire, but which arrived at that in one hundred sixteenth of a second. Simple voltaic electricity is capable of greater mechanical effort, under any given arrangement of conductors, than an induced electro-magnetic current, but the electro-magnetic current travels through lengthened conductors with a considerably superior rate of speed. The electro-magnetic current sent forth from induction-coils possesses a treble velocity of transmission, and resists consequently a three-fold working speed as compared with simple voltaic electricity. It was hence obvious that induced, and not voltaic electricity, must be adopted for the wide Atlantic service, where the ultimate commercial success of the enterprise would be mainly dependent upon the number of signals which could be forwarded in any given time or distance.

In the early experiments made to determine the rate of movement of the electrical influence along telegraph-wires, it appeared that it could pass through hundreds of thousands of miles in a single second of time. When however a submarine cable was operated upon, with telegraph-wires coated with gutta-percha and running beneath an ocean and through the sea, instead of being freely suspended in the air, it seemed that scarcely thousands of miles were traversed in a second. Different experimenters, too, arrived at different results for the rate of speed. In a paper read by Mr. Edward Bright, at the meeting of the British Association in 1854, the statement was made that the velocity of electric currents in underwater cables varied from 1000 miles per second to 10 miles per second, but in submarine line did not exceed one thousand miles per second; this gentleman had also inferred from experiments made in a circuit of 480 miles underground, that the speed of the electric impulse varied with the energy or intensity of the current, and that the slowest current was that in a conductor and conditions in which it was placed. When Mr. Whitehouse turned his attention to this question, his investigations amply confirmed the deduction which had been previously drawn. Working with his pendulum-apparatus he found that the mean or average speed of a current of electricity in copper wire, is about 1400 miles per second. But he also ascertained that that of the induced electro-magnetic current is 4300 miles per second. He determined too that the speed of the voltaic current might be raised under particular circumstances to 1800 miles per second, and that of that the induced current might be augmented to 6000 miles per second.

But what could be the cause of these varying rates of velocities, and of the phenomena in general which the electrical influence was thus proved to suffer when it was constrained to traverse coated underground or sub-marine wires, instead of air-surrounded conductors? Professor Faraday had thoroughly investigated this question so soon as the unexplained phenomena in submarine telegraphs made their appearance, and he had cited the seeming anomaly. When a conducting wire of metal is stretched as an electrical conductor between posts, and is insulated simply by earthenware holders and the circumambient air, the electrical influence runs along it as a simple stream, without any loss of strength from an unevenness of resistance; however, the wires are inclosed in a compact sheath of insulating substance, like gutta-percha, and are placed in water or moist earth, the affair is altogether changed. A new property is given to them, which makes them conductors of the most stable substance, and hold, each the other, fast locked. The inner excited influence keeps the outer reduced force stationary upon the external surface of the insulating sheath. The outer induced force keeps a certain portion of the inner excited one present upon the external surface of the insulating sheath as a charge, and so prevents it from moving as freely onward upon its journey as it otherwise would. The submarine telegraph cable is indeed virtually a lengthened out Leyden jar, and is charged or rather charged with a certain quantity of static electricity whenever a new wire passes through it. It is a reservoir or bottle for the electricity, which has to be filled and emptied, as well as a channel or pipe through which the influence may be poured. When an extent of the submarine telegraph cable is spaced with a 600 miles wire, it is necessary to fill up the bottle in virtue of its length, however narrow its transverse dimensions may be. In the more ordinary practice of artificially induced electricity, the voltaic current is not able to produce a static charge in a Leyden jar. In the case of the coated wire of the electric telegraph it is able to do so, probably in consequence of the comparatively enormous extent of surface which comes to be concerned. Now it is this peculiarity of the action of the coated telegraph-wire which leads to the slower rate at which the electric influence is propagated along its substance. The wire on encountering an occasion, must be filled to saturation with the force before any transmission can be effected, and then must be emptied completely before any new transmission can be made. Mr. Whitehouse was able by his delicate instruments to procure a very beautiful illustrative proof that it is such Leyden jars, and not simply as conductors, that submarine cables, or subterranean coated wires act. He took fifteen miles of the Atlantic cable, consisting of an internal conducting strand, external coats of wax, gutta-percha, and tinfoil, that could be turned up the further end into the air, thus leaving the conducting wire entirely insulated that way. He next took 200 miles of the same cable, and arranged it in precisely the same fashion. He now found that he could fill each of these bottles with an electric charge from the conductor, and discharge the charges to remain for a few seconds in the wire, and then discharge them back through the nearer end, measuring the force of the discharge, and therefore the amount of influence which had been inductively retained in the wires, by the
In some of Mr. Whitehouse’s early experiments it was found that the induced electro-magnetic current took a second and a half, when transmitted through a coated wire 1146 miles long, in consequence of the retarding influence of induction in this lengthened channel. This apparently is a very excellent result—a signal conveyed eleven hundred miles in less than two seconds! It is not enough, however, for the exigency of the case, for on the spelling out messages, the most letters require three or four signals each, consequently with this rate of transmission it would be extremely difficult to send enough words across the Atlantic within twenty-four hours, to enable the company to work their telegraph efficiently. The experimenter, therefore, set himself to see whether he could not find some means of quickening the pace of his too lagging messenger. He ultimately accomplished his object by means of a combination with electro-magnetic coils which enabled the operator, through the simple reversal of the current of the magnet to send currents of different kinds of electricity, one after the other through the conducting wire. Each successive transmission then served to clear away the lagging current of the antagonistic current which immediately preceded it. The remains of the old current which clung about the wire pertinaciously, were completely and rapidly put to the rout upon the stream of an opposite kind being thrown in. When positive followed negative, and negative followed positive, in exact alternation, the current in the line would be strong enough to produce very decided results at the distance of 500 miles, would be rendered at this greater distance almost evanescent. Mr. Whitehouse accordingly proceeded to test the deduction in twofour ways next, by exempting the iron core of the magnet from the power to produce mechanical effects in consequence of its having made certain extended journeys; and then by closely scrutinising its loss of speed at varying distances. The current from a voltaic battery which was inserted by means of an iron core, was transmitted to the magneto-electrometer through wires of different lengths. Where the wire was only a few feet long, 25,000 grains were lifted on the steelyard. With a wire 300 miles long 10,650 grains were lifted. With 400 miles, 3250 grains, and 500 miles, the wire transmitted no electricity at all. Experiments were made with wires ranging from 80 to 1020 miles long, to determine the rate of transmission. With a length of wire of 83 miles, the transmission was accomplished in eight-hundredths of a second. With 168 miles in fourteen-hundredths of a second. With 249 miles in thirty-six-hundredths of a second. With 498 miles in seventy-nine-hundredths of a second, and with 1020 miles in a trifle less than a second and a half. Taking 63 miles as the unit in these respects, he found that the number of miles that the current could travel in one second, was 1, 2, 3, 6, 12. Therefore, if the so-called law of the squares of the distances were correct, the transmission through the 1020 miles of wire ought to have required 144 times as long as the transmission through the 83 miles. In practice, however, the number of miles employed in the distances represented by the series 1, 2, and 3, the rates of velocity were represented by the fractional series \( \frac{1}{4}, \frac{1}{2}, \frac{1}{4} \). It therefore appears, from experiments, that nature is more auspicious to the cause of wide ocean telegraphy, than the assumption of theory.

During the experimental investigation of this portion of the subject, a very surprising and an altogether unforeseen result was obtained. In the attempt to ascertain how small a quantity of battery would prove sufficient to effect a charge and transmit a current, through some thousand miles of the Atlantic cable, Mr. Whitehouse had a piece of apparatus prepared consisting of twenty-five pairs of zinc and silver plates, each about the twentieth of a square inch large, and the pairs so arranged that the zinc plate above became the positive pole and the silver plate below the negative pole. They were separated by distilled water or brine between them. On charging this littlepitan battery, by dipping the plates into salt and water, messages were sent from it through the thousand miles of cable with the utmost ease; and not only so. Pair after pair was dropped without a perceptible diminution of the electrical effect until at last only a single pair, charged by one small drop of liquid was used. Strange to say, with this single pair, and single drop, distinct signals were effected through an uninterrupted series of messages, which were perfectly registered at the end of the cable, in a trifle less than three seconds of time. This remarkable experiment demonstrated how slight a current might be made to give very good results, when a conductor as perfectly insulated as the copper strand of the Atlantic cable was made the channel of transmission.
conditions. Also that induced electro-magnetic currents of a certain determinate intensity, travel more quickly than simple voltaic currents, and that the rapidity with which signals are transmitted by the agency of electro-magnetic currents, can be greatly increased by using opposite electro-magnetic coils, alternately. It was also observed that the diminution of the speed of motion along induction-embarrassed wires was not in so high a ratio as the squares of the distances traversed; that several distinct waves of transmission might be made to run along the same wire. It was also observed that large coated wires transmitted with less facility and freedom than small ones, in consequence of requiring a larger charge to saturate their inductive capacities before they were in a fit state to transmit; and that the smaller ones are better suited for long lines employed in the great ocean telegraphy; and that by the use of small wires, very perfectly insulated, and of electro-magnetic induction-coils of powers carefully apportioned to the dimensions of the wires, signals might be transmitted through a distance of 2000 miles with a rapidity amply sufficient for all purposes of revenue to the Company and of utility to commerce.

It was necessary, then, that an Atlantic cable, which was to furnish a fair promise of success, should have a well insulated conductor. Both the difficulties met with at first, and the consideration that it should be so light as to be easily conveyed across the Atlantic, and easily handled during paying out, and yet be so dense as to be able to sink with facility to the depths of the sea, led to the conclusion that it could be done by a wire, the coating of which might be exposed during deposition. It was also essential that it should be so flexible that it could be readily coiled up in the store-spaces of the factories, and of the vessels employed in paying out, and rolled over the sheaves of the wires without friction. It was for these reasons that the inertia and rigidity to allow of its lying in a tolerably straight line when once in situ at the bottom of the sea.

The plan which is, in accordance with the indications of the above-mentioned experiments, &c., was adopted in preparing a cable for the Atlantic. A strand of seven wires of the purest copper of the No. 22 gauge, was first prepared, it being the sixteenth of an inch in diameter when twisted. The strand of seven wires was adopted in preference to a single wire of the same practical size, because the probability of a destruction of continuity was in this way greatly diminished. In case of any accident occurring it was very unlikely that all the seven wires would be broken in exactly the same place, and so long as only one of them remained sound, the electrical transmission could be carried on. The strand itself was subject to a strain which stretched it twenty per cent., without any appreciable injury to its conducting power being discovered. To show that no accident which could lead to an interruption of the current, could interfere to any important extent with its utility as a telegraphic conductor, one mile of wire eleven times smaller than the strand, was introduced into a gap made in a 600-mile length of the cable, and the effect produced upon the insulated power of the communication was tested. It proved that the transmitting capacity of the cable was only diminished by one thirty-seventh part.

When the copper strand was prepared, it was rolled upon drums, and then taken from the drums to have three separate coatings of gutta percha applied. Thus the aggregate diameter was thus brought up to about three-eighths of an inch. The gutta percha used for these coatings was prepared with the utmost possible care. It was first rasped into shreds, and washed through many times of fine water, and kneaded for hours in the interior of iron cylinders by steam machinery. It was then squeezed by powerful screws, through dyes, as the strand of copper was gradually drawn along between them, and so made to adapt itself as a compact sheath to the strand. Two or more successive coatings were given to the strand in order that any imperfection left in the first might be compensated and remedied by the next coat applied. The completed core was subjected to a test of 200 pounds to the square inch, by the use of hydraulic power, without the insulated material being at all injured by the force applied.

During the process of manufacture of this core it was submitted to constant examination to prove both that the core was perfect and that the coating was not injured. It was also observed that the insulating power of the gutta percha sheath was as complete as it was required to be. The continuity was proved by passing a voltaic current of low intensity from a battery of a single pair of plates, through the strand, and then causing it to record a signal after issuing from the wire. A battery of low intensity was employed for this purpose, because it made the test so much the more severe. A strong battery might have thrown the current through a slight imperfection which a smaller current would not be able to overcome. The due perfection of the insulation was tried by turning up into the air the end of the length of core about to be examined, and by then connecting one pole of a voltaic battery of five hundred pairs of plates, to each extreme of the core, the other pole with the earth, a magnetic galvanometer being suspended within a coil continuous with the strand. So long as the insulation of the strand was fairly perfect, the copper wires became charged with a considerable charge of electricity, which could not escape, and so no current was produced through the strand, and no deflection of any consequence appeared in the magnetic needle. When the insulating sheath, on the other hand, was imperfect, the electrical charge leaked through the imperfections to the earth, and so got back to the opposite pole of the battery. In this way a current was set up in the wire to supply the leakage, and the magnetic needle was deflected from its position of equilibrium, the deflection being in proportion to the amount of the current. A voltaic battery of five hundred pairs of plates was employed in detecting imperfect insulation, in preference to a weak one, because a strong current would force a passage through an imperfection which might be too slight to allow a weak current to pass.

A second idea was also adopted, which was to institute a plan devised which enabled the testing for both continuity of the strand and insulation of the sheath to be carried on simultaneously. A voltaic current can pass through a charged Leyden jar without either the current or the charge being destroyed, if the length of cable under examination was joined up into a loop or endless ring, and a voltaic battery of five hundred pairs of plates had one of its poles connected with the conducting strand of this ring, and the other pole with the earth; and then a current of low tension was also introduced into the circuit of the ring, so that its current flowed round continually, from pole to pole, through the strand. An insulated bell was also so placed in the circuit, that the usual way of connecting the bell needle, before held magnetically fast, and caused the bell to sound. Another bell instrument was so arranged that it was rung whenever the current from the five hundred cell battery began to run, in consequence of electrical leakage, with undesirable speed. The feeble battery in the circuit rung its bell whenever the circuit was broken. The strong battery out of the circuit rung its bell whenever an outflowing current was set up through the strand, in consequence of the insulating sheath being broken.

During the prosecution of these experiments the very remarkable discovery was made, that the insulating power of gutta percha is very materially affected by temperature. A high temperature seems greatly to impair its insulating power, and a considerable temperature restores it to its original excellence. An opportunity was taken, when a single flake or tier of the completed cable was lying at the bottom of the receptacle in the yard of the manufactary at Greenwich, to watch the changes which the natural variation of temperature during forty-eight hours produced in its conducting capability. When the thermometer stood at 45°, the deflection of the galvanometer needle was barely 3°; but when the thermometer rose to 59°, the deflection had reached 14°. The next day, with sunshine and cloud made the tell-tale needle traverse out and in with surprising rapidity. There is fortunately reason to conclude that the bottom of the Atlantic will supply the low temperature essential to the good performance of the insulating material. The last sentence might be a statement of Dayman of the Cyclops, have enabled him to determine the deep-sea temperature over a very considerable range, and are abundantly confirmatory of this fact.

The core was put upon a spool as many miles' length of many of these cores were joined into longer extents in a very ingenious way. The gutta percha was scraped from the ends for a short distance, and these were placed in contact. A piece of copper wire was then attached by firm brazing to one side of the joint, and another of the same wire, to the opposite side, being there brazed again. A second binding was then effected outside the first in precisely the same way, and several layers of gutta percha placed over the whole by the
aid of hot irons. In case of the core on each side of the joint being at any time so dragged that the ends of the strand were broken, this outer investment of wire would unroll spirally without being detached from the strand. Thus the electric continuity of the strand would be preserved. The core was of rolled steel, rolled at the same time with the cable, and afterward drawn to shrivel the iron so as to leave an absolute core of approximately one inch in diameter. The outer investment of wire was really a sheath of about three and one-half turns of wire, the strands being forcibly driven into the opening made by these turns of wire, and at the same time the outer skin of wire was drawn over them, the core being perfectly protected from the weather and from injury.

Every two miles of the completed core were wound upon channelled drums with deep flanges, iron shot at the rim, so that they could be rolled about and made to perform their work in the cable without being allowed to rest. The conductors which were used in supplying the cable with the core core, one of the ends was attached to the outgoing core of the compressed cable, and so the contents were unrolled from the drum as the external metallic wires were spun round the core. During the performance of the work is prepared, and during the work to which it is subject, we find that the pitch and tar, was compactly wound round the core to act as a bed for the external metallic sheath. Then eighteen strands, each of seven wires of charcoal iron, were twisted firmly round the core. The strands and the cable were made by precisely analogous machinery. A large horizontal table, containing seven bobbins in the circumference in the case of the strand machine, and eighteen in the case of the closing or finishing machine, was whirled round by steam power with a speed well adapted to the work, and each wire was up through a hole in the middle of the table, and so invested with a twisted whorl of wires or strands, given off from the bobbins as the table revolved. The strands were used, in completing the cable, instead of solid wires, because by doing so the power of soft iron was largely lost. The extra material used, were obtained. The external investment of iron was solely designed to protect the covered core from mechanical violence during the act of submergence, and to confer upon it a convenient amount of weight for effecting its descent to the bottom of the ocean.

Each strand-machine, during the manufacture of the cable, was worked day and night, and in twenty-four hours span ninety-eight miles of wire into fourteen miles of strand. The several strand-machines, working simultaneously even twenty-four hours transformed 2058 miles of wire into 294 miles of strand. As much as thirty miles of cable have been made within twenty-four hours. At one time all the wire-drawers in England were required to be available to supply the demands of the machinery, and the works had to pause for a short space. The entire length of wire, iron and copper, spun into this wonderful structure, amounts to 335,500 miles; a length sufficient to encircle the earth thirteen times! The completed cable weighed from nineteen hundredweight to one ton per mile, and proved to be able to bear with impunity a direct strain of five tons. In the salt water the weight of the cable would, however, not exceed fourteen hundredweight per mile; and as the greatest depth of the Atlantic is only about nine miles, there is little more than two miles, and a certain portion of the weight would necessarily be borne by friction against the particles of the water as the rope sunk, it was anticipated that the cable would never, under any circumstances, be required to meet a strain of more than one ton and a half.

The Atlantic cable is to be worked at the bottom of the sea by means of electro-magnetic currents called forth by an instrumental agency of a somewhat complicated kind. First and foremost in this agency is the primary source of the working influence, stands Mr. Whitehouse's "Perpetual Maintenance Battery." This battery consists of large plates of platinated silver, and amalgamated zinc, mounted in cells of gutta percha. There are several plates, both of silver and zinc, about 30,000 miles. The diagrams show that the terminal bar of metal at the bottom of the cell, and all the silver plates hang upon a similar bar at the top of the cell, so that thus there is virtually but a single stretch of silver, and a single stretch of zinc in operation. Several arrangements are reserved even when the strand itself of either silver or zinc is to be removed for repair or renewal without stopping for a moment the operation of the battery. As any one lamina becomes imperfect, it can be taken out from its groove, and replaced by another. The polarity of the cell is such as to cause the active plate to assume the positive, or oxidising, character, while the other plate takes the negative or oxidizing character, and the active plate is in the manner of an ordinary voltaic battery. Under this arrangement, brilliant flashes are produced, accompanied by a loud cracking sound. The points of large pliers are made red-hot in five seconds when placed between them, and iron screws burn with vivid scintillation. These brilliant effects are, however, inconvenient in one particular. They are produced at the expense of the apparatus. The metallic surfaces from which they are emitted, are rapidly burned away during their continuance. In order, as far as possible, to alleviate this effect, or, at any rate, to check it during the transmission of electrical signals, by means of a key presenting a very large surface of metal. A horizontal bar, fastened at the top, turns backwards and forwards pivot-wise, and tills its edges against twenty flat brass springs resembling those of the key, and forming a bed for the key on each side. A constant slight leak of the current is also continuously maintained through a car of platinum wire placed in water. By this contrivance the injurious force of the sparks is mitigated, and the life of the battery prolonged. The current maintaining this magnificent tenalled Titan battery at work does not exceed a shilling per hour.

But it has been stated that the voltaic current is by no means a fleet messenger compared with other agents which are at the command of the electrician. Consequently it is not the electric stream generated in this mighty battery which is designed to be actually sent across the Atlantic on the performance of telegraphic service. This primary power is only a means of generating a much more powerful system, of a force to convey the energy of a more speedy traveller. The voltaic current, generated in the battery, is transmitted to a piece of complicated apparatus known as Mr. Whitehouse's "Double Induction Coils." These coils are arranged in pairs, and each coil consists, first, of a thick copper wire, six to eight feet long, which is wound round gutta percha enveloping the bar; next of several miles of comparatively fine silk-covered copper wire, coiled round the gutta percha sheath and bar; and finally of a mile and a half of silk-covered coarser copper wire coiled round outside the inner coil. These coils are placed in this order in the cable, with a view to their proper connection or communication or connection. Now the inside iron bars, here, are intended to be made into temporary magnets by the action of electrical currents circulating through the coils. The outer coil of coarse wire carries the battery-current round the iron to make it a temporary magnet. This coil therefore is the primary or generating coil. The inner coil of finer wire has a new independent current set up in it by the instrumentality of the temporary magnet; as the primary current makes a magnet, so the magnet makes a secondary current in the previously quiescent coil, and this secondary and magnetically induced current is which is sent off brisk enough to perform the work of rushing across the Atlantic. This independent secondary current is therefore the transmission current, and the coil in which it is produced is properly the transmission coil. To Mr. Whitehouse the merit is due of winding the secondary transmission coil round the magnet directly, and inside of the generating coil. By this means he means the necessary additional coil of wire increases its capacity on account of the greater propinquity. The coils are used in pairs, because each one inductively increases the power of its neighbour, and in return has its own energy inductively increased as well. The great heating power of the battery-current is rendered harmless by the size and extent of the primary coil through which it is passed. If at any time, by accident, the current find a short course for itself in consequence of the silk covering of the wire being injured, the accident is immediately indicated by the rapid rise of the temperature of the coil.

The transmission-current generated in the inner wire of the double induction-coil necessarily gets considerably weakened when it has passed through a distance of 1800 or 4000 miles. It does not do so, however. As no electrician's plan to set this weakened current immediately to work to print or record the signals transmitted. The weakened transmission-current is merely caused to open and close the outlet of a small device, the working of which is recorded separately. The strand of the cable is continued into a coil of fine wire, wound about a bar of soft iron. When the transmission-current flows through the coil, the bar becomes a temporary magnet, which has the direction of the needle of a compass (north or south) by the nature of the line negative (or positive) that is sent through the coil. The pole which is north when the transmission-current is positive, becomes south when the transmission-current is negative. Near to the temporary magnet a permanent magnet is so placed that it can travel forwards upon a wire as it is actuated by the temporary magnet. The north pole of the permanent magnet is attracted by the south pole of the temporary one, and vice versa; so that as the polarity of the
temporary magnet is reversed, the permanent magnet is
casued to traverse. When it traverses one way, it opens
the outlet of the local battery by effecting a contact and
causes it to print; when it traverses the other way it shuts
off the current of the local battery, so that it is constrained
to reverse its movement.

It is the peculiar advantage of this relay-instrument (as it
is called) that the temporary magnet has no other work to do
than to turn the permanent magnet upon its almost frictionless
axis of support, for it then acts merely as a relay, and is
commonly employed in the class of instruments. The
arrangement is so sensitive that the apparatus may be put in
action by a fragment of zinc and a silicene pressed against
the tongue. These relays may indeed be ordinarily heard
clicking in action, and the tone of the instrument, when
the large induction-coils are in operation within a few
feet of them, actually doing a little business on their own
account, although not in communication with any current,
and transmitting the same signals and messages as those which
are being forwarded through the agency of the induction-
coils. As the poles of the induction-coil magnets are re-
versed, the poles of the relay-magnets are actuated different
ways. Mr. Whitehouse has made the instruments even more
effective by applying a second permanent magnet, so that it
can be made to produce a screw-action to diminish the
attraction acting on the working magnet, either way.

When the printing battery is brought into operation by
the relay, as just described, it records, by the agency of one
or more of Professor Morse's instruments. In this instrument a
ribbon of paper is unrolled from a hollow cylinder by a train
of clock-work, and as it is unrolled, a sharp style, mag-
tetically actuated, indents a series of dots or lines upon the
paper, so that the style is picked down but for an instant, it
is a dot that is impressed. When it is kept down for more
than an instant a lengthened line or dash is left, because the
paper ribbon is being drawn along beneath the style. In
order that the dash be magnetically controlled to inscribe
the dash or the dot, it is necessary to hold up both the
magnet in action, and drawn down by a temporary magnet
formed by the printing battery current, when in operation. A
tin iron bar, enveloped by a coil of the printing battery wire,
is stronger than the spring when it becomes a magnet, and
drags it down.

The dot and dash-code of Professor Morse is adopted for
the Atlantic service, because there is but one wire in the
cable, which must be made to express, at least, all the letters
of the alphabet, all the numerals of our system, the
combinations of the dot and dash can be readily caused to effect this; thus
dot and dash, — is taken to signify a; — — to signify
b; — — — to signify c; — — d; — — — e, and so on. Mr. C.
Brown's party have invented a very ingenious piece of apparatus in
which the same elements of a single wire are used, but without
issuing from a free and a strapped bell. It is possible that
this apparatus will some day be adopted by the Atlantic
Company for their service.

The British Government granted to the Com-
pany the use of the fine 91-gun ship Agamemnon for
paying out one half of the cable into the Atlantic, and con-
missioned the paddle-wheel frigate Leopard to act as its
tender. The United States Government sent over the mag-
nificent new heavy frigate Niagara, to carry the other half,
with the paddle-wheel steamer Susquehanna for a tender.
The Agamemnon proved to be singularly adapted for its
work in consequence of having one square space as a hold,
40 feet deep and 20 feet wide and deep. In this space the 1200
miles of the cable were able to be laid down on
one circular coil. The Niagara was not by any means so
adapted for the service, and had to be considerably altered
in her internal arrangements after she came over to England,
the cable even then being divided between her and the paddle-
wheel coil. The arrangements made by the engineer for the
paying out, planned that the cable should come up from the
hold of the ship, sweeping round a central block occupying
the middle of the lower coil, and then wound out and in over four
grooved sheaves. This was arranged by simply passing the
sheaves along a short distance above the poop-deck, and plunging
over a fifth sheave, resting over the stern, into the sea. A
friction drum, also geared to the sheaves, was embarked by
blocks, by which it was intended, so that it could be gripped
more or less tightly when ever occasion arose. Provision was
also made to register electrically the speed with which the
paying-out vessels moved through the water, the rate at
which the cable was payed out, every instant, and the strain
which was thrown upon it. Electrical signals, too, were to
be made through the cable, from end to end, every second,
proving the maintenance of its continuity. The engineer's
calculations fixed from four to five miles as the sound. But it
was deemed impossible that the pay-out of the cable should be effected. An external guard was placed over
the screws of the vessels engaged in the work, to prevent
the cable being injured in case any need should arise for
ประธาน in the operation, at which was deemed possible. A small journeyman engine
was prepared for accomplishing this picking-up labour.

Provision was also made for dropping the portion of the cable
in the act of being submerged to the bottom of the sea on
the return journey, so as to be ready for use at any moment when
the storm was past, the dropping being accomplished by
means of very strong supernumerary ropes kept ready for the

The end of the month of July was selected for the accom-
plishment of this wonderful enterprise, because Lieutenant
Maury had ascertained, by the accumulation of a large series of observations, that the Northern Atlantic is in the most
favorable condition for any work of the kind in this season
of the year. The presence of either fogs or icebergs, and gales
of wind are almost unknown at the period, excepting just off
the western coast of Ireland. Lieutenant Maury also marked
out the track the vessels ought to endeavour to take. The
degree of latitude running from Newfoundland to the track
running directly from Trinity Bay in Newfoundland to
Valentia Harbour in Ireland. But all practical navigators
are aware that it is altogether impossible to direct a ship
across a true great circle track. Such a track would require
the course one restricted to a quarter of a point of the
circle, and in which the departure from a true great circle
path was no more than eight-tenths of a nautical mile. If
one ship had sailed in the great circle route, and the other
in the polygonal route, each moving at the same rate of speed,
the two would have met exactly at the end of the track, with
no errors approaching to this amount. Lieutenant Maury
consequently planned a polygonal route from Valentia Har-
bour to Trinity Bay, in which there were only six changes
of track one restricted to a quarter of a point of the
circle, and in which the departure from a true great circle
path was no more than eight-tenths of a nautical mile.

red Asia. It is continued in the Northern Pacific through the
Island Lines, and it stretches at the bottom of the Atlantic
as a sort of submarine shelf from Cape Race, in Newfoundland
and Cape Clear in Ireland, Newfoundland and the British
Islands being really projecting extremities of the higher portion
of the shelf. This plateau rests precisely in the course along
which the telegraph cables follow; and, after having been
washed along by the Gulf stream, until they were finally
dropped in this region as a kind of perpetual snow storm,
consequent to the passage of water from rapid onward move-
ment, into fluid that is comparatively at rest. There the
remains of organized existence are brought up by the deep
sea plummets prove to be so perfect notwithstanding their
fragility, that there can be no doubt the depth where they
are free from all kinds of mechanical disturbance, and so in
the precise condition which must be the most conducive
to the safe preservation of an electrical cable once deposited
in their recesses. Lieutenant Berryman, of the United States
navy, carefully sounded through the extent of this submarine
plains, and described it as being smooth and slightly inclined
from the upper to the lower atmosphere. He revised these soundings shortly before the sailing of the
expedition for the submergence of the cable, going over
the same track again, and fully confirmed the general facts of
the relatively slight depth of the plateau, and the abundant
preservation that is to be looked for; and this is a conclusion
that can be reported a greater degree of density in the depths
of different positions than Lieutenant Berryman had conceived.
On the 6th of August, 1857, operations commenced. There
were present, Captain Agassiz, 'Nature'; Agassiz's opera-
tions, 'William Mind', and 'Advice', six steamers intended to
assist in various parts of the operations. The shore-end of the cable was taken on shore from the 'Nia-
gara,' by a number of boats. And then took place a ceremonial
inauguration of the lines of Lord-Lyndhurst of Ireland,
landing the extreme end of the cable, and drawing it into
to a tent where electrical batteries had been placed, on
the beach of Valenicia Harbour. The engineer was doomed, how-
ever, to a mortifying disappointment. A slight accident
happened to the cable on this trip, but this was repaired,
and the ships proceeded. By the morning of the 10th they had
got out 200 miles to sea, and the cable conveyed messages to
and from the land and the ships with the utmost facility; the
persons in the following the voyage by boat by
hour. On the 11th, however, the engineer found that 335
nautical miles, or 380 statute miles, of cable had been sub-
merged; and, knowing that that was far too much in
proportion to the straight line distance, he concluded there was
also a break. The commission to the middle of the cabled
ination of the grip of the machinery was therefore made; and
this modification appears to have been unskilfully attended to
by one of the subordinates. The cable was stretched too
ightly; it snapped, and went to the bottom, at a depth of
twelve thousand feet, equal to forty times the height of St.
Paul's. Preparations are being at this time, March 1858,
for immediately resuming the attempt. The lost
portion of the cable has been replaced; and government
ships of Great Britain and of the United States are under
orders again to assist in the national enterprise.

Electrical Telegraphs now render useful service in several
cities of America. In New York eight bell-towers are con-
ected with each other, and with the central tower over
the City Hall square; and a bell at these places
uates an alarm of fire. At Boston a comprehensive plan is
acted on. A central station has been selected, in which the
principal instruments are placed. Two wires take a very
circumvent route from this station; one, ingeniously arranged
on the same standards, is made to ringing the fire-
bell towers in the city, where it acts upon machinery which
strikes on a large bell whenever an impulse is transmitted
through the wire; the other, much more extensive, proceeds
to all the street or ward signal-stations in the city. At
all of these signal-stations is a box containing a magnetic appa-
tratus, under the care of a keeper. If a fire break out in any
part of the city, a message is sent to the nearest signal sta-
tion; the man transmits a signal to the central station, whence
an electric impulse is sent to all the bell-towers in the city,
the ringing of which conveys the required information. It is
obvious that other public information besides that of
fires, may be disseminated throughout the city by similar
means. There are about forty-five miles of wire in this telegraph
at Boston. There seems every reason to believe that, now
the telegraph wires follow so many sub-way routes in the
Capital of the United States, they will gradually be brought within
the scope of the system.

ELECTRICITY OF ORGANIC BEINGS. Plants and
animals, under certain circumstances, exhibit electrical
phenomena. These however are not so constant or fre-
quent as is the electrical phenomena of water and certain
water animals. Of the former species there is one
that is now known to exist between the great forces of nature,
as Light, Heat, Chemical Action, and Electricity, it is
perhaps master of surprise that so few electrical phenomena
are exhibited by organic beings.

In Plants, it appears that during growth electricity is
developed. Pouillet filled several pots with earth, and
placed in them different kinds of seeds, and then insulated
them. During the process of germination no electric distur-
bage was discovered, but when the seeds began to sprout
a gold-leaf electrometer had its leaves separated at least half
an inch from each other. Pouillet concludes that the vegeta-
tion on the surface of the earth must produce a vast amount
of electricity, and be an active cause of its phenomena in
the materials that it surrounds; for instance, they have
observed that the wires in the bark and pith of a growing tree,
have obtained decided indications of the presence of a galvanic
current. These exhibitions of electric disturbance are undoubt-
dedly dependent on the chemical changes going on in the plant,
and the continued growth, but this is not the force in nature
representing another. Under the influence of heat and light
the electric and attractive forces are brought into play, and
the motile force of the growth of the plant as well as all
other phenomena that can be ascribed to them.

In the Animal Kingdom the same indications of the
presence of electricity is afforded during the activity of
the vital functions. Matteucci has observed a considerable
deflection of the galvanometer when wires were connected
with the heart or the reproductive organs. Experimen-
ters have obtained similar results. It has been
supposed that these phenomena were due to the chemical
changes going on in the body of the animal, but they cease
on the death of the animal. Free electricity is ex-
cited by the movements of the human body. There is
made evident by rubbing the feet on a woollen rug, when,
on applying the hand to a gold-leaf electrometer, the presence
of electric disturbance is indicated. Some persons are
more liable to this development than others, and Dr.
Carpenter says there are persons "who scarcely ever pull off
articles of dress which have been worn next the skin without
sparks and a crackling noise being produced, especially
in dry weather."

Recent experiments of Matteucci and Du Bois-Raymond
have shown not only that free electricity is developed in
animal bodies, but that there is a true galvanic current both
in the muscles and nerves. Galvani attributed the move-
ments, first observed by his wife, induced in a frog's leg by
plates of copper and zinc, to a purely animal action. Volta
showed that the movements observed by Galvani were de-
dependent on the chemical action developed in the metals.
Matteucci observed the peculiar sensibility of the nerves and
muscles of the frog to galvanic action, and made use of the
leg, preparatory to this development than others, in many of his experiments. The mode of using it was simply to take the leg of a recently
killed frog with the crural nerve dissected out of the body,
but remaining in connection with it. The leg was then
inclosed in a glass cylinder, covered with an insulated
nervous, and the nerve allowed to hang freely at its open end.
When two points of the nerve were thus prepared were brought in contact
with any two substances in a different electrical state, the
muscles of the frog's leg are thrown into contraction.
By this galvanization of the nerve he could produce
creants of electricity in the muscles of animals, by cutting into
them, and placing one extremity of the nerve deep in
the wound and the other at its tips. The experiments of
Matteucci were followed up by Du Bois-Raymond, who
arrived at the following conclusions:—1. That galvanic cur,
rents may be observed in any limb of any animal whether
cold or warm-blooded. These currents in some limbs are
directed downwards, in others upwards. They are of
different intensity in different limbs; but their intensity
and direction are always the same in the same limb of differen

2 D 2
individuals of the same species. 2. The electro-motive action on which these currents depend does not arise from the nervous system. The currents as composed of the different tissues, the nerves, muscles, and tendons, in an electric point of view, are quite homogeneous. 3. These currents are produced by the muscles. If any undissected muscle of any animal be brought into the circuit longitudinally, the excitation is always found to act in the direction of which depends on the position of the muscle.

The current of the whole limb is nothing but the resultant of the partial currents which are engendered by each muscle of the limb. 4. The law of the muscular current may be expressed as follows: "Any point of the natural or artificial longitudinal section of the muscle is positive in relation to any point of the natural or artificial transverse section." 5. By means of the above-meant transverse section is affected by the muscular current appearing in one instance an upward one, in another a downward one, which occurs according as the upper or the under of the two transverse sections is made to touch one of the ends of the galvanometer wire, whilst the other is applied to the longitudinal section of the muscle. This is true even as regards shreds of muscle consisting of only a few primary fibres, and such as only admit of observation by the microscope. 6. The nerves are possessed of an electro motive action according to the muscles. Whilst still in organic connection with the muscles, and forming part of a circuit in which the muscles give rise to a current, the nerves simply play the part of an inactive conducting body, provided their own current be prevented from passing through a single point.

There are certain animals which possess the power of accumulating electric force within their bodies, and of discharging it at will in a violent form, and with the exception of some insects and Mollusca, which have been said (though this is doubtful) to communicate sensible shocks, these animals are all included in the class of Fishes. About seven species of this class, belonging to five genera, are known to possess electric properties, and it is curious that these genera belong to two of the most peculiar branches of the class, and though each has a limited geographical range, one species or other is found in almost every part of the world. Thus, the three species of Torpedo, belonging to the Ray tribe, are found on most of the coasts of the Atlantic and Mediterranean, and sometimes so abundantly as to be a staple article of food. The Gymnotus, or Electric Eel, is confined to the rivers of South America. The Sirturus (more correctly the Malapterurus), which approaches more nearly to the Salmon tribe, is the parent of the Serpent, Trichurus, or Indian Sword-Fish, an inhabitant of the Indian seas; and the Tetraodon (one of the genus allied to the Diodon, or Globe-Fish) has only been met with on the coral banks of Johanna, one of the Comoro Islands. These fishes have a vast number of varieties with the same organs, and it seems probable that the phenomena which they exhibit, and the structural peculiarities with which these are connected, are essentially the same throughout.

The peculiar characteristic of is the power of giving to any living body which possesses the shark resembling in its effects that produced by the discharge of a Leyden jar. This is of very variable intensity in different species and individuals, and at different times. The Gymnotus will attack and paralyse horses, as well as kill small animals; and the discharges of large fish (which are 30 feet long) sometimes prove sufficient to deprive men of sense and motion. The effects of the contact of the Torpedo are less severe, and soon pass off; but the shock is attended with considerable pain when the fish is vigorous. The electric organs appear to be charged and discharged to a certain extent at the will of the animals. Their power is generally exerted by the approach of some other animal, or by some external irritation; but it is not always possible to call it into action, even in vigorous individuals. It usually diminishes with the general feebleness of the system, though sometimes a dying fish exerts considerable power. All electrical fishes have their energy exhausted by a continued series of discharges; and the electrical forces conveyed into South America to collect a number of wild horses and drive them into the rivers, in order to save themselves, when they pass, from being injured by the fish. If excessively exhausted, they may even die; but they usually recover their electrical energy after a few hours' rest.

The Torpedo, from its proximity to European shores, has been most frequently made the subject of observation and experiment; and the following are the most important results arrived at by different inquirers:—That the shock received by the organs of sensation in man is really the result of an electric discharge, has now been fully established. Although no one has ever seen a spark emitted from the body of one of these fish, it may be supposed that an electric discharge is sent along the nape of the fish, acting upon the organs of the senses; and in such manner as is essential to the proper reception of the shock, that two parts of the body should be touched at the same time, and that these two should be in different electrical states. The most energetic discharge is procured from the Torpedo by touching both the back and the belly, and the head and the tail; the point of the shock to the sensitive organ appears to be the source of the difference in the relative state of different parts of the body; those which are near to it being always positive in respect to those more distant. Dr. Davy found that, however much Torpedoes differ from each other in size, they are all single pointed, and he states that, when one surface only is touched and irritated, the fish themselves appear to make an effort to bring the border of the other surface, by muscular contraction, into contact with the head, because the discharge is then more than one can stand; but when both surfaces are placed together, the fish will not attempt to make the two surfaces touch, but will be content with the feeling produced by one point of the organ being touched; and he adds, that if one surface is touched and the other is not, it will be done by a fish. If a fish be placed between two plates of metal, the edges of which are in contact, no shock is perceived by the hands placed upon them, since the metal is a better conductor than the human body; but if the plates are placed in water the shock is experienced, and if placed on the back and in contact on one side, the fish itself will turn over so that one of its sides is placed against the opposite plate, and the discharge is then felt. The situation of the electrical organs of the Gymnotus is essentially the same with those of the Torpedo; but the opposite electrical states are found to exist, not between the dorsal and ventral surfaces, but between the head and tail; and the connection is formed between these two extreme points.

It has been ascertained by experiment, that the manifestation of this peculiar power depends upon the integrity of the connection between the nervous centres and certain organs of the body. These organs are divided among various animals, and are organs of a flattened shape, and occupy the front and sides of the body, forming two large masses, which extend backwards and upwards from each side of the head. They are in the Sirturus there is no electrical organ so developed as those just described; but the thick layer of dense cellular
tissue, which completely surrounds the body, appears to be subservient to this function; it is composed of tendinous fibres interwoven together, and of an alkaline substance contained in their interstices, so as to bear a close analogy with the cellular partitions in the special organs of the Torpedo and Gymnotus. The organs of the other known electrical fishes have not yet come under the notice of any anatomist.

In all these instances the electrical organs are supplied with a mass of very great size, larger than any others in the same animals, and larger than any nerves in other animals of like bulk. They all arise in the Torpedo from a ganglionic mass situated behind the cerebellum, and connected with the medulla oblongata by the name of Mignone's ganglion. It has been given; the first two of them issue from the cranium in close proximity with the fifth pair, and have been regarded as belonging to it, although their real origin is different; whilst, from the distribution of the third electrical nerve to the stomach, after sending its principal portion to the elec-

trical organ, it would seem analogous to the eighth pair or pneumogastric.

The electrical nerves in the Gymnotus are believed to arise from the spinal marrow alone; and those of the Sphyrna are considered as arising from the spinal marrow and the sides of the intestines. The integrity of the nerves is essential to the full action of the electrical organs. If all the trunks be cut on one side, the power of that organ will be destroyed, but that of the other will remain unimpaired. If the trunk be destroyed on either or both sides, the power is retained by the portion of the organs still in connection with the centres. The same effects are produced by tying the nerves as by cutting them. Even slices of the organ entirely sepa-

rated by a thread are capable of exciting the electrical properties. Discharges may be excited by irritation of the brain when the nerves are entire, or of the portion of the divided trunk distributed on the organ; but on de-
stroying the electric lobe of the brain the electric power of the whole organ will remain. All the other ganglionic centres may be removed without impairing it. It is remark-

able, however, that after the section of the electrical nerves Torpedoes appear more lively than before the operation, and acted on the flagellate five longer than others not so injured, which are excited to discharge frequently. Poisons which act violently on the nervous system have a striking effect upon the electrical manifestations of these fishes; thus, two grains of musarum of morphia were found by Matteucci to produce death after about ten minutes, during which time the discharges were very numerous and powerful; and stychania also excited powerful discharges at first, succeeded by weaker ones, the animals dying in violent convulsions. When the animals were perfectly dead, and had no signs of life, the slightest irritation occasioned discharges; a blow given to the table on which the animal was placed being sufficient to produce this effect. If the spinal cord were divided, how-

ever, no irritation of the parts situated below the section caused the discharges. Matteucci observed that the electric power is suspended when the Torpedo is plunged into water at 32°, and is recovered again when it is immersed in water of a temperature from 68° to 66°; and that this alternation may be repeated several times upon the same fish. But if the temperature be raised to 69° the Tor-

pedo soon ceases to live, and dies while giving a great number of violent discharges. (Carpenter.)

From these facts it is evident that the electric force is developed over no one organ, but rather in the whole body. From this it has been sometimes hastily inferred that the electric and nervous forces are identical. This, however, is not more probable than that the contractile force of the muscles is identical with the nervous force. The best explanation of the pheno-

mena appears to be the correlation of these forces. They are convertible forces, the one being capable of generating the other; the force generating being always the representative of the force generating it. The use of these electric organs is unknown; and it is stated that the discharges are given when few of the fishes which it kills by its shocks, and this is the case with the Torpedoes. Dr. John Davy conjectures that the electric discharges decompose the water, and supply oxygen assist in respiration. Dr. Carpenter suggests that this peculiar gastric action of this organ, which we observe in 1800, in which he was at least partially. His honest and manly nature ever disdained as much to trample overbearing on the humble as to crouch meekly before the powerful. He despised business with great celerity, and for the most part with success. But causes were not set before him with that clearness of his mind and parti-

ties were not suffered to bring forward all they had to state with that fulness and freedom, which alone can prevent miseducation, and ensure the due administration of justice. [Carpenter, Principles of Physiology, General and Compar-

ative; Professor Matteucci, Electro-Physiological Researches; Philosophical Transactions, 1850; Matteucci, Lectures upon the Physical Phenomena of Living Beings, translated by Perier; Du Bois-Raymond, On Matteucci's Letter to Dr. Bence Jones, Abstract of Du Bois-Raymond's Researches in Animal Electricity; H. Bence Jones, Abstract of Du Bois-Raymond's Researches in Animal Electricity.)

ELEOTRIS, a genus of Acanthopterygious Fishes belonging to the family Gobidae. Like the Oubies the species have flexible and pointed first dorsal fin, and an appendage behind the vent, but they have the ventral fins separate and six gill-rays. The species are inhabitants of the fresh waters of warm countries, and conceal themselves in the mud.

E. doratrus, the Sleeper, is a large fish. It is found in the West Indian marines. Other species have been found in Africa, India, and the Mediterranean.

ELIDONE. [SPiGROD.]

ELLENBOOROUGH, [CUMBERLAND.]

ELLENBOOROUGH, LORD. Edward Law was born November 16, 1750, at Great Salkeld, in the county of Cumber-

land. He was the fourth son of Dr. Edmund Law, bishop of Carlisle. He received his rudimentary education at the residence of the late Peers of Cumberland, and the late Rev. Mr. Christian, who then resided at Docking in Norfolk. He was re-

moved thence in 1762 to the Charter-house School, London, and placed on the foundation. In 1768 he was entered of Cambridge, and on February 11, 1772, taking his degree of B.A. he removed to London, and became a student in the Inner Temple. Having been called to the bar, and ac-

quired by a short preparatory practice the needed technical knowledge, he soon took his place among the chief members of the profession engaged in the defence of the revenue-witnesses. In April 1791 Sir Edward Law succeeded Lord Kenyon as lord chief justice of the court of King's Bench, and was created a peer by the title of Baron Ellenborough, of Ellinborough in Cumberland, by patent dated April 10th, 1802. He was afterwards made a privy counsellor. In the House of Lords in 1805 he strenuously opposed any concession to the Roman Catholics. On the trial of Lord Melville in 1806 Lord Ellenborough voted against him. In 1813 he was nominated one of the commis-

sioners to negotiate with the Prince of Wales. In 1814 he was one of the judges who presided at the trial of Lord Cochrane, and in 1818 on the trial of Hone. [Hone, William, £.I.] In November of the same year he retired from the bench. He died December 13, 1818, at his seat, Ellinborough, and in 1820 he was succeeded in the title by his eldest son, who is now Earl of Ellenborough. Lord Brougham, in his 'Historical Sketches of Statesmen,' makes the following remarks on his character as a judge:—"The Term Reports bear ample testimony to the vigour of this eminent individual's capacity during the eighteen years that he filled the first place among the English common-law judges. ... He was sometimes irascible, and sometimes even violent. He was nothing but one of the most manly and sincere of men, and his honest and manly nature ever disdained as much to trample overbearing on the humble as to crouch meekly before the powerful. He despised business with great celerity, and for the most part with success. But causes were not set before him with that clearness of his mind and parti-

ties were not suffered to bring forward all they had to state with that fulness and freedom, which alone can prevent miseducation, and ensure the due administration of justice."

ELLESMERE, [WORCESTERSHIRE.]

REVISED BY N. LAWSON GOWs was born in London, January 1, 1800. He was the second son of the first Duke of Sutherland, and brother of the present Duke. He was educated at Eton College, and afterwards at Christ Church, Oxford. He left the university in 1820, in which year he was married to Miss Julia Harri-

Sans in Surrey, since disenchanted by the Reform Act. At a time when the German language was little studied in England he distinguished himself by a translation of the 'Faust' of Goethe, in two volumes, which was more than
once reprinted before the author resolved to withdraw it from circulation. It had been more than a year since 1785, when he had been followed by 'Translations from the German,' and Original Poems, by Lord Francis Lewson Gower; £8o, London, 1824. This small volume consists of translations of seven lyrical poems by Schiller, one by Güste, one by Gailis, and three by Körner, and six of the original poems. He was M.P. for Sutherlandshire from 1826 to 1830. In 1827 he was made a lord of the treasury. From January 1830 to July 1830 he was chief secretary for Ireland, and from July to November 1830 he was secretary at war. On his death of his third wife, in 1835, having received as his inheritance the Bridgewater estates, which his father had inherited from the last Duke of Bridgewater, he assumed the name of Exeter. From 1835 to 1846 Lord Francis Egerton was M.P. for South Lancashire. In the autumn of 1839 he commenced another translation, 'Voyage round the Mediterranean.' He wintered at Rome, whence he sailed for Malta in April 1840, and having landed on the coast of Syria, made a tour in Palestine. In 1841 he was elected rector of the university of Aberdeen. In 1843 he published 'Mediterranean Sketches, by Lord Francis Egerton,' 12mo. In this volume the poem called 'The Pilgrimage' records some of the most interesting impressions of his tour in Palestine. It is followed by extracts from his journal and letters, and a new edition of the original poem, with several additions, was published in 1858, 'The Pilgrimage, and other Poems,' 4to. In 1846 he was created Earl of Ellesmere and Viscount Brackley, titles nearly corresponding to those of his lordship, the Earl of Ellesmere; who, at the time of his death, bore the title of Viscount Bridgley, Lord Hardwicke previously held that of Baron Ellesmere. The Earl of Ellesmere was elected President of the Antiac Society in 1849. In 1855 he was created a knight of the Garter, and in the same year was appointed colonel-commandant of the Lancashire yeomanry cavalry. He was also deputy-lieutenant of Sutherlandshire. He died Feb. 21, 1857.

Besides the works before mentioned, the Earl of Ellesmere published the 'Camp of Wallenstein,' and other Poems; the poems of the Beppo, the 'Sieges of Vienna by the Turks,' from the German of K. A. Schimmer, and other sources, 16mo, 1847; 'Military Events in Italy,' translated from the German, 12mo, 1851; 'Life and Character of the Duke of Wellington,' 12mo, 1852; 'History of the Two Tartar Conquerors of China,' from the French of J. P. D'Orleans, 8vo, 1854.

The Earl of Ellesmere, at his residence, Bridgewater House, Cleveland Square, London, had one of the very finest gardens of the metropolis, and possessed, besides the residence, an extensive and beautiful park.

Kingdom. He inherited the chief portion of it as a part of the property of the Duke of Bridgewater, but he made some additions to it himself, and in a very handsome manner he made it accessible to the public. We ought to mention that his lordship has a very great respect for the ancient poet, Shakespeare, known as the Chando Shakespeares, with a view to its forming a portion of the projected National Gallery of Portraits.

ELLIOTT, EBBENEZER, the Corn-law Rhymer, was born March 17th, 1781, at the New Foundry, Marsbo, near Rotherham, Yorkshire. His father, a clerk at the foundry, was an ardent politician, and a stern ultra-conservative disserter of the Bovem sect; and he employed his 'brother Herean, Thomas Wright, the Barnsley tinker,' to baptize his son—as the poet relates in his 'Autobiography,' published soon after his death in the 'Athensum' (January 18, 1850). The elder Elliott (also an Ebenizer) was accustomed to go into his own room every fourth Sunday, to persons of a similar persuasion, with great oration within or about the four miles to hear him, and on the week-days he 'ioy delight, to declaim on the virtues of slandered Cromwell and of Washington, the rebel,' as he pointed to prints of them while hugging on the hearth, and he expressed that 'is the key which will unlock all the future politics' of the Corn-law Rhymer. The young Ebenezer was regarded as a dull child, loved to be alone, made little progress at school; where he could never master grammar, or attain to vulgar fractions, and he had been in confirmed dunces; and eventually, out of sheer hopelessness, was sent by his father to work in the foundry. At the foundry work, however, he was thought to be even cleverer, but his father did not know he adopted also the workman's evil habits, and for a while gave way to intemperance. But from sinking into thoroughly vicious courses his early love of nature saved him. A copy of Shenstone's 'English Botany,' lent him by a friend, led him to collect botanical specimens and after a while he became interested in poetry that treated of his favourite flowers, and court scenes. He soon became a diligent reader, studying 'after Milton, Shakspere—then Osian, then Junius,' and so on, while much of 'Barrow,' he says, 'I was far too young to understand and too unproficient to condense.' In time too he began to write verses himself, though his early efforts, he confesses, were unsuccessful; and he set himself doggedly to learn in his own way grammar and even French, but could master neither. Mean- while he was employed as a clerk, and had been induced to purchase the foundry business on credit, and from his sixteenth to his twenty-third year Elliott "worked for his father as laboriously as any servant he had, and without wages, except an occasional shilling or for a night's lodging, and he was accepted as his apprentice, and he passed (in his seventeenth year) his first published poem, the 'Vernal Walk;' this was followed soon after by 'Night,' 'Wharrcliffe,' and others; and Elliott, between his rhymes and political, began to be a local celebrity. He had the good fortune to form the acquaintance of Southey, who was earnest in giving him the full benefit of his own wide experience in poetical studies, and Elliott was in after years proud of proclaiming that Southey taught him poetry. Happily for his purposes, he did not let his respect for the genius or his gratitude for the kindness of the laureate lead him to become an imitator, or to tame down his wild notes to the orthodox tunes. Between 'Wharrcliffe' and the 'Corn-law Rhymes,' he published in 1823 'Love,' and another poem, accompanying 'Earl of Ellesmere,' 1854, which was a volume of poems written by his lordship on the death of his son.

Elliott's father was too much hampered by the liabilities he had incurred, and his want of capital, to carry on the foundry with success. After a time young Elliott commenced business on his own account. A battle of both houses of Parliament, falling there he removed to Sheffield, where in 1818, he, at the age of forty, recommenced the battle of life as a barista merchant, with a borrowed capital of 1001. Here he had a series of commercial successes, built himself a handsome residence in the city, and his enterprising spirit of the flourishing business till the great panic of 1837, when heavy losses caused him to contract the scale of his dealings. He finally withdrew from business in 1841, and retired to a pretty country residence he had built for himself on an estate of Great Tunbridge, near Tunbridge, and there he resided at ease in his circumstances, in the centre and oracle of a circle of admiring friends, till his death, which occurred on the 1st of December, 1849, having lived to see the first season of the Oxford University Press, the country which he had laboured so earnestly to bring about.

Elliott says of himself, in the 'Autobiography' already quoted: 'There is not in my poetry one good idea that he thought to be a bad, or that he falsely put into print. It is to be observed that many of them are of some passing event, or was written to serve some temporary purpose. None of it is the result of a long meditated design, or the completely formed issues of a vivid and vigorous imagination; or, on the other hand, the unpremeditated melody of a heart imbued with happy thoughts and fancies—singing as the wild-bird sings. Nevertheless it is true poetry, albeit often very harsh and ragged. It is the passionate protest against wrong—the fiery remonstrance with the wrong-doer—spurning the cold incumbrance of peace and inviting to the battle of life in the current of the free flow of poetry. The great public evil that came nearest home to his own hearth, that as it seemed to him, which was inflicting dire mischief on the labouring classes of his country, and which was undermining the prosperity of the manufacturing structures of the country and as he believed, of the country generally, was the Corn-Laws; and he resolved to set forth the mischiefs those laws were producing, and the greater dangers they were threatening. He had, therefore, long ago commenced to view the 'Corn-law Rhymes' began to appear in a local paper, and their effect on the hard Yorkshire artisans was immediate and lasting. And their influence was assuredly well-earned. Rude and rugged in language, intensely bitter, often as might be expected, inaccurate and sometimes unjust in their denunciations, they yet showed
everywhere a thoroughly honest hatred of oppression, and fellow-feeling with the oppressed and suffering. With quite a Crabbe-like familiarity with the poverty of the poor, they displayed a far warmer, deeper, and more genial sympathy. The wrath and the pathos, too, uttered in the most impos-
and the most direct words, were yet conveyed in
genuine music, which made its way at once to the heart.

The respect and the applause which was offered to the general public they were equally successful.

The 'Corn-Law Rhymes,' published in a single volume with 'The Raster,' at once made Eliot's name famous. Many people began to pass along the street 
language was occasionally objected to, but it was generally felt 
the language was really a part of the man. Noticing 
the objection in the preface to a new edition of the Rhymes, Eliot asked, "Is it strange that my language is fervent 
as a welding heat, when my thoughts are passions that rush 
burning from my mind like white-hot bolts of steel?" But 
while, this a sufficient explanation of what reads so like excessive vehemence, serves really to take off the edge of his poetic declaration, while it destroys the impression of his prose, as placing within the category of passion which ought to be the result of reason. Eliot followed his 'Corn-
Law Rhymes' by publishing in 1839 the 'Village Patriarch,' another but longer corn-law rhyme, much the best of his longer pieces, a work in which, with many other 
he is a great master of prose is the ability to write in a way 
and his name has been known, the superior power to 
ought to be the result of reason. Eliot followed his 'Corn-

EMB.

ELM.

due to Mr. Cockerell, who also designed the sculpture of the pedestal.

To understand the importance of Elmes's great work, it would be necessary to review the history of architecture, and especially the adaptation of Greek models, during the course of some years preceding the date of the St. George's Hall design. The proper use of ancient models had been introduced by A. W. Pugin into the Work of the first half of the century. In many parts of the kingdom buildings were erected, supposed to be classical, but which realised neither art nor the lower quality, the very imitation. Thus an idea had been given for many years that the Gothic was out of date in itself, whilst at variance with modern requirements, as to be in itself the cause of the failure in certain ambitious pro-
ductions. Elmes, however repeated the proof how that it was possible to use the works of preceding minds, and yet to realise the grandest new conception. Considered as to the attributes of art, Elmes's work is more Greek than many modern buildings which may exhibit even accurate reproduction. The design may well be claimed by this country as amongst the noblest efforts of architecture in Europe.

After years spent most worthily in the pursuit of art, Elmes had not realised anything commensurate with the ex-
and merit of his exertions. An average of 400l. a year, subject to deductions for travelling, clerks, office and other heavy expenses, left little of the £2000 which he received from that work which forms the chief adornment of a rich provincial town; and after his death a subscription was raised to provide a moderate income for his wife and child.

ELODIANI. [Tortuosa.]

EMBERIZIDÆ.

Family of birds belonging to the order Insectivora and the tribe Conirostræ. The most distinguishing genus of the family is Emberiza. It comprises however other genera. The general relations of this family are given under Passerinae. We shall confine ourselves here to the British genera of this family known under the name of Buntings.

Plectrophanes.—Buck short, thick, conical, the edges of both mandibles slightly curved inwards; upper mandible smaller than the lower, with a small palatal knob. Nostrils basal, oval, partly hidden by small feathers. Wings long and pointed; the first and second quill feathers of nearly equal length, and the longest in the wing. Legs with the tarsi of moderate length; anterior toes divided; lateral toes equal in length; hind toe strong; claw elongated, and nearly straight.

Lepidopicus (Gould), the Lapland Bunting. It is the Emberiza lapponica and E. caesia of other writers. Though a native of the arctic regions, Mr. Yarrall records five instances of its being taken in Great Britain. It is found in Siberia and near the Uralian chain. Towards win-

Lepidopicus.—Buck short, thick, conical, strong, hard, and sharp-pointed; the edges of both mandibles curving inwards; the upper mandible narrower and smaller than the under one, and its roof furnished with a hard bony and projecting palatal knob. Nostrils basal and rounded, partly hidden by small feathers at the base of the bill. Wings of moderate size; the first quill shorter than the third, which is the longest in the wing. Feet with three toes before and one behind, divided to their origin; claws rather long, curved, and strong.

E. miloti, the Common Bunting, is the most common species of this genus. It remains in the British Islands
throughout the year; and on account of its very familiar presence in corn-fields, it is frequently called the Corn-Bunting. It builds its nest in April, and lays from five to eight eggs; which are of a reddish-brown, purpled ground, streaked and spotted with dark purple-black. It feeds on the seeds of the grasses, of the Polygonum, of sorrelles, and of cereal plants; also on Coleopterous Insects.

In the plumage of this species the upper parts are of a light yellowish-brown streaked with blackish-brown, each feather being of that colour along the shaft; lower parts pale yellowish-gray, each feather of the fore neck tipped with a triangular spot of brownish-black, the fore part of the breast and belly elongated and; a bistre or brown. E. schenckii, the Reed-Bunting. It is also called, according to MacGillivray, Black-Headed Bunting, Reed-Sparrow, Water-Sparrow, Ring-Bunting, Ring-Bird, Ring-Fowl, and Gholo. It frequents marshy places, where it is seen perched on willows, reeds, sedges, and other aquatic plants. It feeds on insects, seeds, and small Moluscus. The nest is placed among aquatic plants, and is composed of stalks and blades of grasses, bits of rushes, and the like. The eggs are four or five in number, of a yellowish-gray, with tortuose or angular lines, and irregular spots of black. This bird is easily distinguished from the other species by its black head and white throat.

E. citrinella, the Yellow Bunting or Yellow Ammer. It is also called in English Yellow Yellding or Yolding. Yellow Yowley, Yellow Yie, Yeildock Skute, and Devil's Bird. It is a permanent resident in Great Britain, in cultivated and wooded districts, where it is well known. The back and wings are light chestnut-brown, the central part of each feather brownish-black. The nest is composed of coarse grasses and twigs, neatly lined with fine grass, fibrous roots, and hair; it is placed on the ground or in the lower part of a bush. It lays four or five eggs purplish-white, marked with linear and angular streaks and a few irregular dots of black.

E. cirrus, the Chir-Bunting. This bird is not so common in this country as the last, which greatly resembles. It was first distinguished as a British bird by Colonel Montagu. It is a rare visitor to the south of Europe, and is more frequent in the south of England than in the north. E. hortulana, the Ortolan Bunting. A very few specimens only of this bird have been taken in England. It is common in the southern countries of Europe, and migrates as far northward as the Baltic.

(MacGillivray, Manual of British Birds; Yarrell, History of British Birds.)

EMIGRATION. One of the most remarkable facts in the history of Great Britain is the rapid increase of the population. This increase in the kingdom has been pointed out in the article Census. While the population of France and Germany has increased within the last fifty years in a very small degree; while in Spain, Portugal, and Italy it has been stationary; Great Britain has increased 10,000,000, as given in the census of 1801, to 20,900,000 in that of 1851; and in the middle of 1856, the Registrar-General estimated the population of England and Wales alone at 19,044,000: Ireland is omitted, as there was no census of 1801. In addition to this increase, swarms have been thrown off to which the ancient migrations from the North are insignificant in their total amount, though the emigration has been less striking from its being not an irruption but a gradual progress. In forty-two years, from 1815 to 1856 inclusive, during which an account of avowed emigrants has been taken, 4,470,319 persons, male and female, have left the shores of the United Kingdom; and these have been enabled to form what may now be termed three mighty empires, subordinate to our own, in Australia, North America, and South Africa; independent of the branch streams which have flown off to Ceylon, the West and East Indies, Guiana, and other British possessions. The United States of America is the only dominion that can afford anything like a parallel, and even that is indebted to us for 2,703,782 persons, who have proceeded thither, the greater proportion of whom have been from Ireland, and chiefly from the year beginning with 1847. The annual average of emigration from 1815 to 1842 was 62,500; from 1847 to 1856, it was 279,816. It should be added, however, that from 1815 to 1824 no records were kept of the emigration to South Australia and New Zealand; but it was certainly under 10,000. (See under the title 'Census', and under the heading 'Emigration' we gave a table of emigration to 1856, which we now complete to 1856:—

In 1857 the total number of emigrants from the port of Liverpool only, was 155,652; of these 9788 were for the North American colonies; 100,948 for the United States; 29,651 for Australia and New Zealand, and 324 for other places. Of these emigrants England supplied 60,898; Scotland, 6161; Ireland, 71,195; and various foreign countries, chiefly Germany, 6414. The emigration to Australia was principally English; that to the United States principally Irish.

Many emigrants, however, proceed to the North American colonies by New York, and no account is taken of the passage either way on the borders between them and the United States. We have accordingly omitted these, and only calculated the number of emigrants who landed in the United States as being 117,000.

The numbers given for Canada are from the Census of 1851 for Western, and the official returns of 1858 for Eastern Canada: the estimated numbers of both in January 1857, were 2,500,000. For New Brunswick they are taken from the Census of 1851, and the official returns of 1853. For Nova Scotia, from the Census of 1851. For Prince Edward's Island and Cape Breton, for the year 1854; and for Newfoundland, for 1854. All have increased since the returns. For Newfoundland the numbers are taken from the Census of 1845, and in 1857 the increase was estimated at 10,000. For Bermuda the authority is the official return of 1853.

In Australia:—

The returns of these colonies are for 1853 and 1854; and in Natal the numbers given are exclusive of 112,988 settled natives.

In these three divisions of the British colonies, there are now representative governments, the privilege of self taxation, and the right of a free press; in short, a complete reproduction of the British Constitution. To other colonies, especially to British Guiana and some of the West India islands, the emigration has been considerable; and some of the emigrants become mixed with an older and in some cases a
coloured or foreign population, we cannot trace the British element so clearly. The effect has been so far good, that the inhabitants of the North American and Australian colonies are, with the exception of the United States, among our best customers. It is not remarkable, therefore, that so much attention has been paid of late years to the subject of the transmission of emigrants thither, and of means for enabling them to settle there in comfort. Government, accordingly, has undertaken to a considerable extent thebusiness of the emigration question, and has provided for emigration was appointed. This officer introduced many judicious plans for rendering the passage of emigrants across the ocean as free as possible from discomfort, and a code of rules was framed to secure this and other objects. The functions of the officers for emigration are now exercised by the Land and Emigration Commissioners. Emigrants are also protected by the Passengers’ Act. The Act 6 & 8 William IV. c. 5, passed in 1833, having proved insufficient for the purpose, several amended acts were passed, of which the latest is the 18 and 19 Vict. cap. 119, passed in 1856. Its objects are to regulate the number of passengers in each ship, and to provide for their proper accommodation on board; to ensure a proper supply of provisions and water for their consumption, and to prevent perjury, and to ensure to secure a sufficient number of boats in case of accidents; and to protect emigrants from the numerous frauds to which at various stages of their undertaking their helplessness and inexperience expose them. Under this Act, by the 28th day of every month, the agreement, the Passengers’ Act compels the captain to victual the emigrants the same as if the voyage had commenced; and they are entitled to remain on board forty-eight hours after the ship reaches her destination.

As a further protection to emigrants, and to enforce the provisions of the Passengers’ Act, government emigration agents are appointed for the ports of London, Liverpool, Plymouth, Southampton, Glasgow and Greenock, Dublin, Cork, Belfast, Tralee, Derry, Hull, Liverpool, London, Chatham, Medway, and Londonderry, and Galway. These officers act under the immediate directions of the Colonial Land and Emigration Commissioners. They procure and give gratuitously information as to the sailing of ships, and means of accommodation on board; they know the emigrants, and whenever applied to for that purpose, they see that all agreements between ship-owners, agents, or masters, and intending emigrants, are duly performed. They also see that the provisions of the Passengers’ Act are strictly complied with, viz., that passenger-vessels are sea-worthy, that they have on board a sufficient supply of provisions, water, medicines, &c., and that they sail with proper punctuality. They attend personally at their offices on every weekday, and afford gratuitously all the assistance in their power to passengers bound for the tropics, they assist them in arranging their affairs, and to obtain redress where oppression or injury has been practised on them.

In the colonies there are Government Emigration Agents at the following places:-
Canada.—Quebec, Montreal, Toronto, and Hamilton.
Neu Brunswick.—St. John’s, St. Andrew’s, Chatham (Miramichi), Bathurst, Dalhousie, and Richibucto.
Australian Colonies.—Sydney, Moreton Bay, Melbourne, Geelong, Portland Bay, Hobart Town, Launceston, Perth, Fremantle, Adelaide, and Auckland.
Cape of Good Hope.—Cape Town, Port Elizabeth, and Simon’s Town.

The duty of these officers is to afford gratuitously to emigrants assistance in their power by way of advice and information as to the districts where employment can be obtained most readily, and upon the most advantageous terms, and also as to the best modes of reaching such districts.

The Emigration Commissioners, while they have funds for the purpose, grant passages to New South Wales, Victoria, and South Australia, to persons strictly of the labouring class who may be considered eligible emigrants. The funds are now limited, and the administration of them the Commissioners act as trustees for the colonies, and are therefore bound to look exclusively to colonial interests. They do not consider therefore how distress in this country may be benefited. The largest, and most suited for the wants of the colony may be procured and sent out. In deciding what clauses are most suited to the wants of the colonies, the Commissioners are guided by reports and instructions received from time to time from the governments of the respective colonies, either direct or through the Secretary of State. The Commissioners are occasionally also able to grant passages to Western Australia; but they have no funds for assisting persons wishing to emigrate to the North American colonies. In British Guiana, the Governor, under Ordinance No. 7, of 1854, sect. 4, is authorised by proclamation to name the places from which emigration on bounties is permitted, and to fix the rates of bounty for the introduction of emigrants, under the advice, competent and willing to engage in agricultural labour.

Emigration is one of the ‘modes of relief’ contemplated by the Poor Law Amendment Acts (4 & 5 Wm. IV. c. 76; 5 & 6 Vict. c. 51; 12 & 13 Vict. cap. 103; and 13 & 14 Vict. c. 101). In some years large numbers of emigrants were emigrated with the assistance of funds obtained under the Act 4 & 5 Wm. IV. By sect. 62 of that Act owners and rate-payers are empowered to raise money on security of the rates for the purposes of emigration, under the authority of the Poor Law Commissioners. The sum so raised must not exceed half the average yearly rate of the preceding three years, and it must be repaid within five years. The money is advanced to emigrants by way of loan, and is recoverable, together with interest at 5 per cent, if the emigrant consents to emigrate, refuse to do so after the expenses of emigration have been incurred; and the loan is also recoverable if persons who emigrate shall return to this country.

In 1856, under 13 & 14 Vict. c. 105, the guardians of any parish or Union are empowered to expend out of the rate fund, of 10/- upon the emigration of any poor person belonging to the parish or to any parish in the Union, without the necessity of a parochial meeting to give their consent. But the gross amount expended must not exceed the limit fixed above, and the majority of the Guardians of the parish of the settlement must express their concurrence in writing in the resolution of the Board of Guardians for such expenditure. This written concurrence must be transmitted, together with a list describing the proposed emigrants, to the Poor Law Board, who are to issue their order to confirm the resolution. The 13 & 14 Vict. c. 101, sect. 4, enables Boards of Guardians, under similar restrictions, to expend money in and about the emigration of persons or children under sixteen having no settlement, or whose settlement is uncertain. But it requires that no emigration of any such orphan or deserted child shall take place without the consent of such child given in petty session, and unless a certificate thereof under the hands of two justices shall have been transmitted to the Poor Law Board. Certain conditions are inserted by the Poor Law Board in all orders sanctioning the emigration of poor persons, of which the most material is, that the party emigrating shall go to some British colony not lying within the tropics, or the Mediterrenean, and that the emigrant shall undertake to expend one shilling in the pound on the net annual value of rateable property.

The Bounty System derives its name from the mode in which the proceeds of land sales are applied in obtaining immigrants. In this case persons who introduce persons into the colony receive so much per head, according to the terms of agreement. The contractors engage to find persons willing to emigrate, and undertake to land them in the colony. They are limited to a certain number of the respective British colonies. In New South Wales 51,736 persons were introduced from 1831 to 1842 under bounties. The mode in which unoccupied land is disposed of in the colonies has a most important bearing on the health and welfare of immigrants. By the application of a general principle of law, the waste lands in the British colonies were considered to be vested in the Crown, and that every private title must rest upon a royal grant as its basis. But since 1831 another principle has been established, that the Crown holds the lands in question for the purposes of the public good, not merely for the existing colonists, but for the people of the British empire collectively. It must be noted that the following Act and its provisions (Appropriation of Land Sale Act for the Australian Colonies (15 & 6 Vict. c. 36)) prohibits land being alienated by her Majesty, or by any one acting under her authority, except by sale, and in the manner directed by the Act.
Down to the year 1831 no regular or uniform system of selling land appears to have been adopted in the British colonics. The mode of selling land varied from place to place, and was determined by the occupation of the land under the name of quit-rents, money payments, or the cultivation of the soil; but these conditions were not effectually enforced, and in fact it was generally found impossible to enforce them. Large grants of land were made, and as cultivation was not enforced, and no roads were made through these tracts, they interrupted the course of improvement. Under the old system, lands in the colony of the Cape of Good Hope and Port Jackson were granted to individuals. One western acres, have been disposed of for less than 46,000£. In Prince Edward's Island the whole of the land was granted in one day to absentee proprietors upon terms which have never been fulfilled. The influence of these proprietors with the 'present Government prevented such measures being adopted as were calculated to enforce the settlement of the grants, and consequently the greater part of them remained chiefly in a wild state. ('Report of Mr. C. Buller, M.P., to the Earl of Durham, on Public Lands in British North America, 1838.) This Report contains an account of the system of granting lands in each of the provinces of British North America; and in all of them it appears to have been injurious to the public interests.

In Canada, commissioners were appointed under the royal sign manual to act as a Land and Emigration Board. The sale of the waste lands of the Crown throughout the British colonies was regulated by the commissioners, and they refused the request of the removal thither of emigrants from this country, when the land-income was appropriated to this object. This board was a subordinate department of the Colonial Office. But the disposal of the waste lands is now, by various Acts of the Imperial and provincial parliaments, vested in the local governments. The regulations vary considerably in their details, but we give a summary of the conditions and prices of the waste lands in the North American, Australian, and Cape of Good Hope Colonies.

In Canada there are detached Clergy Reserves for sale in most of the townships surveyed prior to 1841. These reserves are now vested in the Colonial Government by the 10 Vt. Law, and are being sold at the rate of 16s. per acre. They are now thrown open for public sale. The lands reported by the chief agent for emigration at Quebec to be most worthy the attention of emigrants, are the townships Pei, Welessley, Maryborough, and Mornington, covering an area of 200,000 acres, in the county of Wallace. The prices of land in these townships (as of all Clergy Reserves), are regulated by the quality of soil and situation, and average from 5s. to 10s. currency per acre, one-tenth of the purchase-money, usually the amount of such sales towards the cost of the erection, which is usually about 1s. per acre. The sale is to be in nine annual instalments, with interest. One million acres of land were also appropriated for school purposes by the legislature in 1849, and the school lands in the counties of Bruce, Grey, and Huron are now open for sale to actual settlers upon the payment of five years' purchase, consisting of 10s. per acre, payable in ten equal annual instalments, with interest. The first instalment to be paid upon receiv-
each of the colonies in which they offer land for sale." The Commissioners in pursuance of this object issue occasionally a 'Colonisation Circular,' which contains matter calculated to be of essential use to emigrants or persons who intend at some future day to settle in the colonies. EMMETT, a name used by early English writers for the Ant. [ANT.]

ENAMEL (of Teeth). [Tissues, Organic, S. 1.]

ENCEPHALANTOS, a genus of Plants belonging to the natural family Euphorbiaceae, the species being found in Africa. Like many of the other forms of Cynadaceae plants they yield starch in their stigmas, which are prepared by the natives and eaten; hence these plants are known by the name of Cassava-Root or Kaffir-Root.

ENCHELIS, a genus of insularialmecales. The species E. sanguinea and E. puticulus, according to Meyer, form the Red and Green Snow-Plants which have been described as Conferta, and referred to Protococcus. [Snow, Ekn.]

ENDOMOSIS, a name given by Durochet to the process by which fluids pass from the exterior to the interior of a cell. This process seems to result from two distinct agencies, which are always brought into operation where fluids pass through a membrane. The one is the imbibition of the fluid by the protoplasmic cell-membrane; and the other is the mutual diffusion of miscible fluids. From the investigations of Matteucci and others there can be little doubt that the passage of a gas or liquid through an animal or vegetable membrane is but the result of the imbibition of one of the fluids which are absorbed by solid bodies. This process is carried on with various degrees of force in different materials, and seems to depend on the degree of attraction subsisting between the particles of the solid and those of the fluid. Matteucci found that when glass tubes of about three-quarters of an inch diameter were filled with fine sand previously dried, and introduced without pressure, and were immersed at their lower ends into the following liquids, the action of imbibition raised the liquids in the tubes to the following heights:

<table>

<tr>
<td>White of Egg, diluted with its own volume of water</td>
<td>35</td>
</tr>
</tbody>
</table>

In these cases the imbibition took place at first rapidly, then more slowly, and ceased entirely at the end of ten hours. When thick solutions of gum, or starch, or fixed oils were placed in freshly opened tubes of atmosphere, any imbibition took place, and it was but little more when strong saline solutions were used. The degree in which different fluids pass into different solids will be seen in the following table:

<table>
<thead>
<tr>
<th>Material</th>
<th>Poured Glass</th>
<th>Saw-dust</th>
<th>Alcohol</th>
<th>Water</th>

<td>183 mill.</td>
<td>60</td>
</tr>
</tbody>
</table>

Thus showing that water passed more freely than alcohol into sand, but less freely into saw-dust, and both fluids passed with equal facility into pounded glass. The size of the tubes employed in the above experiments is essentially the determining result. The fluids rose higher in proportion as the temperature increased. This enables us to understand the influence of heat on life by the physical effects it produces.

Not only is the passage of fluids from the exterior to the interior of a cell facilitated by the attraction between the cell-wall and the fluids, but the fluids on either side of the membrane have a tendency to mix with each other, which cannot but assist in this process. Processes of diffusion and absorption are essentially analogous. The fluids which pass through the pores of the seepum, which is not equally penetrable by them, then the one which is most readily imbied will tend to occupy the capillary passages of the seepum, and will thus come into contact with the liquid on the opposite side. This combination will pass until both fluids are represented in the pores of the seepum; and as fast as that which occupies these pores is removed by diffusion, so fast will it be renewed on the other side,—just as oil continues to ascend through the capillary channels in the wick of a lamp, so long as it is being supplied. In the same way then an endosmotic current is produced, the force of which will depend upon the diffusion-powers of the two liquids, and upon the difference of the attractive power which the capillary tubes of the seepum have for the two liquids.
Thus when a solution of sugar or gum is on one side of the septum, and water on the other, the water is the most readily imbibed, and consequently the mixture placed on one side through the other, takes place at the surface of the septum in contact with the more viscous liquid. But at the same time this liquid is tending to diffuse itself through the water which occupies the capillary channels of both, and which is not restored to the septum, which is only attracted by it in a less degree than the water, a portion of it finds its way in a direction opposed to the principal current, and diffuses itself through the water on the other side, thus constituting Endosmose. Thus it happens that the direction of the principal current, which is determined by the attractive power of the septum for one or for the other of the liquids; though the diffusion-power of the liquids through each other will help to determine its force. When alcohol and water are both present, and composed of animal membrane, the endosmotic current will be from the water towards the alcohol, because the former liquid more readily "wets" the membrane, and consequently tends most strongly to occupy its capillary passages; but on the other hand, when the separation is made by a thin lamina of castor-oil, the endosmotic current is from the alcohol towards the water, because the former is most readily imbibed by the septum. It has further been ascertained by the experiments of Matteucci, that when an organic membrane is employed as the septum, the current is in a direction entirely affected by the direction in which the endosmotic current traverses the membrane. Thus, when the skin of the Torpedo was employed, with a solution of sugar on one side of it and water on the other, though the endosmotic current from the water to the sugar, yet this current was so strong enough to raise the interior liquid to 80° when the water was in contact with the internal surface of the membrane, in the same time that was occupied by its rise to 20° when the external surface of the membrane was turned towards the water. Again, when the mucous membrane of the stomach of a dog was used as the septum, and its external (or muscular) surface was placed in contact with alcohol, the principal current was found to be with this side, as to raise the liquid in the tube to 130°; whilst if the internal (or mucous) surface of the membrane were placed in contact with the alcohol, and the muscular surface with water, the current was only sufficient to raise the liquid 6 degrees in the same time; so that it is evident that the transudation of water takes place much more readily from the mucous lining of the stomach towards the outer side of the viscus than in an opposite direction, in virtue simply of the physical properties of the membrane. In fact, according to Proctor, the casein is the casein, the casein; the casein with fresh membranes, Endosmose takes place with equal readiness, whichever of the two sides is exposed to the water.

The direction which is most favourable to Endosmose through skins is usually from the internal to the external surface, with the exception of the skin of the frog, in which the endosmotic current, in the single case of water and alcohol, takes place most readily from the external to the internal surface. But when stomachs and urinary bladders are employed, the direction varies much more, according to the nature of the liquids employed. This variation appears to have some relation to the physiological conditions in which these membranes are placed in the living animal; thus, the direction most favourable to Endosmose between water and a sarcinical solution, is not the same for the stomach of a ruminant as for that of a carnivorous animal; as yet however no positive statement can be made on this subject. When membranes are employed that have been dried or altered by putrefaction, we either do not observe the usual difference arising from the position of the surfaces, or Endosmose no longer takes place; thus affording another indication that it is to the physical condition of the perfectly-organised membrane that it is not repelled by the pressure of the peculiarities which are noticeable in the transudation of fluids through them. The exosmotic current does not bear any constant relation to the endosmotic, as may be expected from the previous hypothesis; though if the liquids have a strong tendency to mutual diffusion, and the difference in attractive power which the septum has for them respectively is not great, each may find its way towards the other; and a considerable exosmose may ensue, with very little change of level. The amount of the exosmotic

which it traverses the membrane; thus, when sugar, albumen, or gum, was employed in solution, its transudation towards the external surface, of all the skins examined by Matteucci, a fact which is without its significance, when it is remembered that it is in this direction that the secretion of mucous takes place on the skins of fishes, frogs, &c.

"Another fundamental fact on which is based the phenomenon of imbibition of liquids into the tissues and canals of the living body, we shall have to inquire how far they are capable of being accounted for on physical principles which have been now brought forward. It has been maintained by some that absorption is merely the peculiar consequence of a difference of pressure; and that it occurs save during the continuance of life. But this is not true, since imbibition will take place into dead tissues, though more slowly than into some parts when living; and the reason of this is perfectly explained by the difference of the condition between a mass of tissue, all whose fluids are stagnant, and another in which an active circulation is taking place. Thus, as Matteucci has shown, if the hind legs of a frog recently killed is immersed for some hours in a solution of salt, little or no change of size will be found that every part of the viscera is so penetrated with the salt, that by touching it with a glass rod moistened with a solution of chloride of iron, a more or less deep blue stain is the result. Now, the same effect is produced in the frog's bladder, which is contained in a very contracted state. It has actually proved that the imbibition takes place in the latter case into the blood-vessels, and that the salt is conveyed to the remotest parts of the body by the circulation, instead of having slowly trickled down through the tissues, as in the former instance, in the case of the dead animal. But further, not only does the movement of blood in the vessels promote the diffusion of liquid, which has been already observed, it also increases the rapidity of the absorption itself in a very extraordinary degree. Thus, if a membranous tube, such as an ink sac, or a piece of a large vein of an animal, be fixed by one extremity to an opening at the bottom of a vessel filled with water, and have a stop-cock attached at the other extremity, and be allowed to remain as above described, the effect of the chloric acid, it will be some time before the acid will penetrate to the interior of the tube, which is distended with water; but if the stop-cock be open, and the water be allowed to discharge itself, the presence of the acid will be immediately discovered (by tincture of litmus) in the liquid which flows out, showing that the acid has been assisted in its penetration of the walls of the tube by the current traversing its interior. Thus, the continuance of circulation is obviously one of the most potent of all the conditions of absorption in animals, and will be confirmed by the press in the dead and living organisms, placed under the same circumstances, may be accounted for in great part, if not entirely, by the stoppage of the circulation in the former.

All such circumstances which are laid down by physiological, as well as by medical, terms, as assuring absorption, are in strict accordance with the physical principles which have been now explained. These circumstances are—1. The ready miscibility of the liquids to be absorbed with the juices of the body. 2. The penetrability of the tissue through which the absorption takes place. 3. The absence of previous distention in the tissues or canals towards which the flow takes place. 4. The elevation of the temperature within certain limits. 5. The vascularity of the tissues, and the rate of movement of the blood through the vessels. And the results of experiments upon recently-dead membranes which retain almost exactly the same physical conditions as those which they possessed during life, but have entirely lost their vital properties, seem most decisively to indicate that the relative facility with which different substances are absorbed, and the direction most favourable to their passage through the tissues, are determined in great part by the physical relations of those tissues (and of the vessels which traverse them) to each other. In this way, then, many of the phenomena of selective absorption are probably to be explained, especially in plants and the lower animals. The special absorbent vessels, however, of Volkmann and others, which are laid down by pharmacological terms, as thus accounted for." ('Principles of Physiology.') [Absorption.]

ENDYMION, a genus of plants belonging to the class of Endogenes, the order Liliacea, and the tribe Hemerocallideae. It has a tubular bell-shaped perianth, composed of six convolute leaves, with reflexed points combined below the
stamens are inserted below the middle of the perianth; the filaments decurrent.

E. _mat»s, the English Blue-Bell. It is also the _Scilla_, the _Hyacinthus non-scriptus_, and _Agrilus matrona_ of various botanical writers. It has linear leaves, with nodding racemes, the flowers bell-shaped, cylindrical; the apex of the sepals revolute; the bracts 2. This is a very common plant, flowering in May in the woods and thickets of England. It is also common in France and Belgium. The flowers are about 1½ inches long. The leaves are shorter than the flower-stalk. The flowers are initially blue, a white variety is however occasionally seen.

ENFRANCHISEMENT. The enfranchisement of copyholders, to facilitate which a great many acts of parliament have been passed, is now, by the statute 15 & 16 Vict. c. 51, been rendered compulsory alike on the lord as on the tenant, on terms which are to be determined in case of difference by the Copyhold Commissioners nominated by the statutes. From the annual reports of these commissioners, which are laid before parliament, it would seem that the holders of copyhold property are gradually availing themselves of the facilities afforded by the statutes; so that in course of time the old tenure by copy of court-roll will become rare, and perhaps unknown. This is one of the many instances showing the tendency of modern legislature to simplify and cheapen the transfer of real property. (Blackstone’s ‘Commentaries,’ Mr. Kerr’s edition, vol. vii. p. 146.)

ENGRAILUS. [Anchoy.]

ENNISTYMOND. [Clare.]

ENTOPHYTA (from _entero_ and _physis_), a term applied to plants found living within animal bodies. The term _Entophyta_ has been applied to those forms of plants which live upon the exterior of organized multicellular plants or animals. It is however difficult to draw the line between these two classes, because it frequently happens that a plant whose spores are deposited in the interior of an animal body, in the course of time finds its way to the surface. The term Entophyte has also been employed to designate those higher forms of plants, more especially the _Orchisidae_ which are found growing on other plants, so that the term Entophyte is more especially used to designate those cryptogamic plants which grow on the skin or mucous membranes of animals. These will be more particularly referred to here. At the same time it should be observed that a large number of cryptogamic plants are found in the living tissues of other plants, and claim to be regarded as Entophytes in relation to the vegetable kingdom.

The study of Entophyta has been invested with considerable interest, since by the aid of the microscope so many of these plants have been detected accompanying various diseased conditions of the animal body. Although they have been perhaps more carefully investigated in the human body, it has been for a long time a familiar fact that many of the lower animals are attacked by these plants in states of disease. Thus the cultivators of the silk-worm have observed the growth of a species of _Botrytis_ in the organs of that animal, producing great destruction amongst them, and the occurrence of this fungus is known by the name of _Muscocline._ [Muscocidina, S. 2.] Caterpillars have been brought to this country from New Zealand, Australia, and China, as curiosities, from the bodies of which a species of _Cystaria_ or _Spharia_ of considerable size is found to project. A species of _Polistes_, a kind of wasp, has been observed in the West Indies to be subject to the attacks of a fungus which appeared on the surface of the body in the form of a growth as large as itself. The common house-fly is often seen in the autumn of the year adhering helplessly to a pane of window-glass from the growth of a fungus on its body, which has not been free from the suspicion of producing even so formidable a disease as cholera. Goldfish, when kept in confinement, as well as water-salamanders and sticklebacks, have been observed to be covered with a fungus (_Achlya prolifera_?) before death.

These facts, and many others, have from time to time attracted attention, which, having been followed up by diligent observations with the microscope, have led to the discovery of a very large class of vegetable bodies taking up their ordinary residence within or upon animal surfaces.

As to whether these plants are the natural products of the bodies on which they are found, as other plants are of the soil in which they grow, or are introduced from some foreign and extraneous source. From

the observations that have been made up to the present time, it appears that these plants are truly in their natural positions in the localities in which they are found, and that they only multiply or become sources of disease when the bodies on which they grow get into a disorderly state. In the same manner the ova of animals have been constantly present in the air and water, only waiting the proper combination of circumstances to be developed in prodigious numbers. The circumstances which predispose to the growth of these Entophyta upon the body, are not better known than those which predispose to the growth of certain contagious. A failure of the ordinary vital powers to carry on the healthy processes of life seems ordinarily to be the inviting cause of such a development of these plants as would constitute a disease.

All the observations that have been made on this important subject have been brought together by M. Robin in his work on the ‘Natural History of the Parasitic Vegetables which grow on Man and on Living Animals’ (Paris, 1855). The following is a classification of these plants:

I. ALGI.

Class _Isozooceae_.

Sub-Class _I. Distomaes._

Genus _Pterospermium_, 11 species.

Sub-Class _II. Malacoceae._

Genus _Gymnospermium_.

Order _I. Hydrozoaem._

Sub-Order _I. Mycophyta._

Family _Cryptococcceae._

Genus _Cryptococcus, 2 species._

Genus _Palmellae._

Genus _Merimapsiopsis ventriculi._

Genus _Lepidophrya._

Genus _Lepisothrix, 2 species._

Genus _Cydodopryma comatum._

Genus _Arthromysis, 5 species._

Genus _Leptotonia._

Genus _Leptotimus, 6 species._

Genus _Houlinites, 3 species._

Genus _Laproplegnyctis._

Genus _Saproplegnyctis ferax._

Genus _Ehlerobryum, 4 species._

Genus _Ectina, 2 species._

Sub-Order _III. Tubibiria._

Family _Ocellarias._

Genus _Ocellaria._

Genus _Zygnum cruciatum._

Order _II. Cryptopneumia._

Family _Chotaphorae._

Genus _Chotaphora aerovecta._

II. FUNGI.

Division I. Arthroporae._

Tribe _Torulaceae._

Genus _Trichophyton, 3 species._

Genus _Microsporon, 3 species._

Genus _Sporodendron musae._

Tribe _Oidaceae._

Genus _Arhochon Schankerian._

Genus _Oidum, 3 species._

Tribe _Aspergillae._

Genus _Aspergillus, 8 species._

Division II. Trichosporae._

Tribe _Ozogaceae._

Genus _Dactylium cogenum._

Genus _Botrytis Basiana._

Tribe _Spororichiae._

Genus _Spororichium._

Tribe _Isaria._

Genus _Isaria, 12 species._

Division III. Cytosporae._

Tribe _Cotylorhizae._

Section _Ascoceae._

Genus _Muco Muco._

Division IV. Chirospora._

Tribe _Coniopsideae._

Sub-Division _Entodiver._

Section _Spheronomet._

Genus _Loboulbenia, 2 species._
Tribe Saropodidae.
Genus Silbium. Buguet, 1855.
Division V. Thecospermae.
Tribe Spharicae.
Genus Spharica. 8 species.
Genus Astrophyton, 2 species.

The following is a list of the distribution of the species of the above genera in the various localities of the animal body.

I. Man and the Mammalia.
A. The Skin.
Triphyllon tenurum. Malmsen. (On Hairs.)
T. sporuloida. Ch. Robin.
T. ulerum. Ch. Robin. (On Ulcerated Skin.)
Microsporon Audouini. Gruby. (Hair Follicles.)
M. notophytoton. Ch. Robin. (Roots of the Hair.)

The most interesting of these species are undoubtedly those which attack man or the animals which he domesticates and employs. With the exception of the Brytis of the silk-worm, the latter have not been much investigated. Those which attack man, and accompany diseased conditions of his body, are better known. They may be divided into those which are found on the skin, and those which are attached to or found in the secretions of the mucous membrane.

1. Entomophyta of the Skin.—Ten species have been noted in this locality. We shall enumerate them in the order in which they are given by M. Robin.

1. Triphyllon tenurum (Malmsen); Triphyllon tenurum; Mycderma of the Pilos Polonici; fungus of the hairs in Herpa tomentosa, fungus of Porrigo scutulata, Acharium Leberti; fungus of the Tegne tomentes, Basil: Rhizophyte, Gruby. This fungus was discovered and described in 1844 by Gruby in the disease called by the brothers Marquise de Téisme to be the cause of the two plants were formerly described as different. The Triphyllon is formed by oval transparent spores, which give rise to articulated filaments. Its anatomical seat is in the interior of the roots of the hair. The hairs and fungi simultaneously increase. The former seem larger than usual, are paler in colour, lose their elas-

Digitized by Google
tidely, soften, and break off when they have risen some one or two lines above the surface of the scalp. In the short cyathus, the fungus grows still more rapidly, so that the normal structure of the capillaries becomes indistinguishable. Sometimes the hair breaks off before emerging from the skin, and the fungus, epidermis, and sebaceous matter, fill the ends of the piliferous conduits, and form the little brown, or rather black, structure which the Trichophyton is the cause of the disease known under the various names above given, and each has given examples of the contagion of the disease by the transmission of the spores. The spores and mycelium of the plants can sometimes be seen, in the form of a white powder, on the roots of the hair or hairs.

The old term of 'Torquous' is still retained, as sometimes the disease disappears, that is, the fungus dies without disappearing. With respect to the name of the most common disease in which the Trichophyton tonsurans appears, the term used by Cassave (Hepras tonsor) is extremely unfortunate. No doubt vesicles are sometimes formed, and it is easy to say that the error of the specific name is a natural symptom of the disease, but it is well known that in the 'Barecdn' or true Herpes circinata of the scalp, in many cases there are no vesicles at all throughout the whole course of the disease. The term used in this country for scrofula is not inconvenient as it is applied with greater justice to Favus. The opinion is entertained that the specific name of the disease after all the facts, and the specific name of Favus tensus expresses well one feature of the disease, the baldness arising from the brittleness of the hairs.

2. Trichophyton (i) spumilis (Robin). Mycorrhiza of the hair. This species was described by Wallach in the Plecton Polonica or circular flattened spores, which have been too little studied at present to permit their exact characters to be stated.

3. Trichophyton (f) tserum (Robin). Lebert has described a fungus in the crusts covering an atomic nicker of the leg.

4. Microsporion Audouini (Gruby). This plant has been studied by Gruby, and its existence, though denied by Cassave, has been confirmed by Robin. It is present in the disease commonly called after William Porrigo decalcaris or Decalcaris (Rush). It differs from the Trichophyton of Tinea tonsurans, by its numerous waved filaments, and by the extremely small size of its spores. It is not found, like the Trichophyton, in the diseased scalp, and Puccinia (s) as well as Alopecia aerygena, the hair then becomes opaque, softens, and breaks off. The Alopecia is rapid, with or without williogia of the skin. The genus is well known, and the epidermis is thin and smooth. There is an affection which should probably be distinguished from the Porrigo decalcaris, or Alopecia circumscripta, and which is characterised by a rapid disappearance of pigment from both skin and hair, with or without Alopecia. M. Batin includes it in his Tinea achromatata, but does not mention the fact that Alopecia is not common. He states that a psoric acid plant is present, but does not describe it. There must however be something more than a fungus to cause the total disappearance of pigment from a considerable portion of dermis. Besides, when the hairs return they are at first white, and only gradually regain colour; but if the williogia were owing to a plant, it is probable they would not grow at all. The disease appears to be allied to those obscure pigmenitary changes which have a much deeper seat than the surface of the body, such as seen by the Trichophyton. This is between the bulb of the hair and the follicle in which the bulb is seated, and never extends beyond the surface of the skin.

5. Microsporion forfar (Robin). In 1840 Eichsteadt discovered a cryptogamic plant in the disease called by William Pijlioniens enodicolor, and more lately Chloasma. Soon after—

wards Sleyter described the same fungus, and lately Spranger has described and figured it. It forms with the epidermis the yellowish-brown scar seen in Pijlioniens.

r. Achromatana Schonleinl; Mycorrhiza of Tinea favosa; Porrigo phlogist (Gruby). Favus of the Hair. Schonlein was the first to suggest that the honeycomb, or yellow favous crusts in the so-called Porrigo decalcaris (Wise), which often forms the inner root-sheath of the follicle. In this observation however he has been anticipated by Weil, who has pointed out that by using a concentrated solution of iron potassa to make the parts transparent, the fungus is found in the follicle round the hair at the place where it passes through the epidermis. In addition to this, the plant is found in depressions on the surface of the skin, forming the yellow honeycomb-like masses which give the specific name Favus to the disease, and which from their frequent thickly-like shape suggested the term scrofula.

The development of the disease as described by Robin after Remont and Lebert. A cuticular elevation is seen, beneath which is a small favus. When the cuticle is raised, a drop of pus sometimes issues; hence there is a purpuric crust, but with this disease always purpuric. Generally however there is no pus or liquid of any kind. The plant grows, and the cuticle over it (supposing it has not been forcibly detached) finally separates, leaving the favus exposed to the air.

M. Batin describes the favus under three heads, which are fundamentally identical, and different only in respect of form:—

1. Favus urcrellariae dissemnia: this corresponds to the Porrigo decalcaris, Tinea diaperina, and Tinea alveolata of other authors.

2. F. sefemina: this is the Porrigo scrofulata, or F. conoffitus.

3. F. aquamara, a form usually called scrofulata, but distinguished chiefly by the irregular distribution of the scrofula, and by the furrowed masses formed by the fungus, the hairs, epidermis, and exudation.

4. Puccinia Favi. The scrofula contains, with epilium and a little exudation, the mass of the Favus; but the Favus has been described, (1860) by M. dejeter, that a different fungus, a species of Puccinia, is occasionally also present. Robin considers it to be only an epiphenomenon, and that it is certainly not present in all cases. The species of this fungus (Favus) is described as a small round body, rounded, and composed of two cells of unequal size, a superior and an inferior. The other extremity is prolonged into a pointed stem or trunk.

There are still three other plants found upon the skin, which need merely be enumerated.

9. Muscor. In senile gangrene, an ill-described fungus, supposed to be the Muscor mucoides of Linnaeus, has been seen on the slopping mass.

10. Aspergilla. In the wax in the external meatus of the ear, Mayer many years ago described a fungus, and Paccini has lately made a similar observation—Lepomltius (e) of the epidermis. An Aspergillus has been seen by M. Oglier in the epidermis of an arm which was irrigated for a long time to keep down inflammation after a gunshot wound. No one else has noticed it. Not only Messers. Robin and Bazin, but Simon and others of the best dermatologists of Europe, have adopted the opinion that the plants are the actual causes of the diseases in which they are found. The contrary opinion is still in vogue in this country, on the grounds that fungi are generally the proofs and consequences of decay, but not its causes; that in the various forms of Tinea a special condition of the skin and hairs appears necessary for the growth of the plant; and that in Tinea favosa (Favus) in particular, a marked feature of the disease occasionally is an hyper-secretion of epithelium and exudation, owing to an hyperemic cutis, before any traces of fungus can be found.

Nevertheless, these arguments, strong as they are, seem to be overborne by the two grand facts that Tinea tonsurans and
ENT 216 ENT

Tinetos fascos can be communicated by transfer of the plant, and be cured with the greatest readiness by the chemical agents which are most destructive to vegetable life. That a special nidos is necessary may very well be admitted by the partisans of this view, since even in the case of epidemic agents a predisposition is necessary; yet no one denies the co-operating cause with the specific and peculiar poison.

It may be desirable to recapitulate the diseases of the skin in which parasitic plants are found:—
1. Tines toxaden, in which the Trichophyton ton."n.sawari.
2. Tines fascos, in which are present the Acchorion Schumanni, and the Puccinia Favi in some cases.
3. Mentagora, or Tinea mentagora, which exhibits the Bich's sign.
4. Phytopea versicolor (Ohiozoma), in which the Microsporon furfur occurs.
5. Porrocost decazana (Tinea aehromata), in which the Microsporon Audouin is found.
6. Pilise Polonese, in which the Trichophyton ton."n.sawari and Trichophyton sporidiae are present.

II. Entophyta on the Mucous Membrane.—The plants forming on mucous membranes, or in the contents of cavities lined by mucous membrane, are of less interest than those which affect the skin, in most cases, are the disease-causing only secondary. We shall merely enumerate them:—
1. Cryptococcus Cerevisiae, Kitting (Torula Cerevisiae), the Yeast-Plant in the bladder, stomach, intestines, &c.
2. Entophyta carotae, Robin (Sorina), in the stomach, intestines, &c.
3. Leptothria buccalis, Robin (Alga), of the mouth.
4. Occidaria of the intestines. (Farre.)
5. Leptophyta urinia, Montague; an Alga described as forming in the urine. It has as yet been scarcely studied.
6. Leptoposum (1), Hannover, Robin; Alga found by Hanover in the pharynx and esophagus.
7. Leptoposum of the uterus.
8. Leptoposum of the urinary mucus.
9. Leptoposum of the eye.
10. Oidium albozana, Robin (Cryptogama) of diptheritis and sputa; Aptophyta. (Gruby.)
11. Fungus of the lungs. (Bennett.)
12. Pharynx in the discharge of glangers.

To this list from M. Robin may be added the so-called Cholera Fungus of Brittan and Budd. It should however be added that no confirmation of the view originally taken by the discoverers, that the fungus discovered in the dejecta of those affected with cholera, in the cause of the disease, has been afforded. The only explanation that can be given of the occasional occurrence of the spores of fungi or spore-like bodies on the mucous membrane of the stomach and intestines is to introduce, with the food. It has been stated above that the spores of certain species of fungi are found naturally on grains of wheat, and only await favourable conditions for development. Such fungi may be constantly introduced into the stomach with the flour of wheat in the form of bread or other kinds of food.

In the study of the vegetable parasites of animals, particularly those of the intestinal canals, it is necessary to be careful not to confound the tissues of certain well-known cryptogamic plants, which may serve as food or adhere to the ordinary food of such animals, with the true Yeast Fungus, Torula, but which I now suspect to be an ergot upon which the animal had fed. The plant consisted of oblong or oval vesicular bodies, apparently thickened at the poles, and filled with a yellow matter, but this appearance is more probably arose from the cells being distilled with a single large, transparent, colourless, amorphous globule, which pressed a small existing amount of protoplasm to each end of the cavities. The cells were single, or in rows, to eighteen in number. For the single cell of comparatively large size had an attached pair of cells, or rows of cells, at one or both ends. Occasionally they are met with containing one or two small round hyaline amorphous nuclei. The isolated cells of the spores, in the form of ellipsoidal bodies, were of a globular shape, very large, and one in length by the breadth of an inch in breadth. The rows measured up to the length of an inch in length. (Leidy.)

(Leidy, A Flora and Fauna within Animals; Robin, Historie Naturelle des Vegetaux Parasites; Baxin, Itinerarium sur la Nouvre de la France, &c.; Bich, S. Schumani, Th. Schumani, and Entophyta; Brittan and Budd, Journal of Microscopical Science, vol. ii.)

ENTRE RIOS, one of the River provinces of the Argentine Confederation, South America, owes its name to its situation, lying on both sides of the rivers Paraná and Uruguay; comprehends however only the southern part of the peninsula formed by those rivers, the northern portion forming the province of Corrientes. The boundary between the provinces runs along the Rio Guaraní, which separates the Paraná and the Mocoreta, which falls into the Uruguay, between 30° and 30° 30' S. lat. The area is about 30,000 square miles. The population is about 25,000.

The surface is gently undulating; it is only broken by hills along the middle portion or interior of the country. This part is covered with forests of low stunted trees. The southern part of the province is low, and especially along the banks of the Paraná subject to inundations. The northern part is occupied by a low swampy tract, known as the Forest of Mesopotamia, which is not navigable, and the whole province is abundantly watered by numerous small streams.

The soil of Entre Rios is in general fertile, and covered with luxuriant herbage. The climate is mild and dry. First frost is seldom fall before the middle of June and the year.

The highest range of the thermometer at the town of Paraná during the year 1844-47 was 96° in January 1844; the lowest, 90°, occurred in the month of June in 1844 and 1846. (M'Cann.) Cultivation is limited to a comparatively small extent. The crop of grain crops are wheat, barley, and maize. Tobacco and cotton of excellent quality are also raised, but the crops are precarious in consequence of frequent droughts. Great damage is also done to all kinds of crops by the locust and locoinds, and sometimes devastate an entire district. The principal grain crops are yacuma, millet, mazua, nandubay, black and white espinillo, gaebacho, and guayabio, but they are generally small, though in much request for carpenter's work and firewood. Vast herds of cattle are reared, but heavy losses frequently occur owing to the severe droughts to which the province is so often subject. In 1846 so great a drought occurred that the grass was everywhere burnt up; and Mr. M'Cann states that the whole of the cattle in the province went off from the feeding grounds in the Interior to the southern provinces and the Hour of 4,000 to 60,000 head of cattle, and one farm 150,000. Horses are bred in great numbers. Owing to the long-continued state of anarchy in the province there are, in the unproductive districts, many slaves and criminals. The rearing of cattle and horses is the chief occupation of the inhabitants. Mechanical employments are almost entirely neglected. The geographical position of the province admirably adapts it for commercial pursuits; but owing to the closure of the navigation of the two great rivers, the disturbed state in which the country has so long been kept, comparatively little commercial progress has yet been made. Now however that the rivers are declared open to vessels of all nations, under the guarantee of the principal maritime powers, there seems to be required only internal peace for the development of the great capabilities of the country.

The exports are principally of hides, horns, tallow, and jerked beef.

The other provinces of the Argentine Confederation, Entre Rios is a federal state, owning but little dependence upon the central government. The government is almost entirely in the hands of a governor, elected for the term of two years. The Congress consists of deputies chosen from the several towns or districts. The revenue is derived chiefly from customs duties.

Except a few families of Guarani origin, the country is almost entirely inhabited by the descendants of Spaniards. The only new arrivals by way of a few adventurers are mostly Italian, who mainly conduct the river trade, and are accompanied by some French and English traders. Some of the large estancias (cattle farms) and saladeros (tallow-melting establishments) are the property of and conducted by Englishmen.

Economic affairs of importance are the large wool-growing industry of Buenos Ayres, joining with Corrientes in the engage-

Digitized by Google
all the subsequent proceedings which have had for their main object the opening of the rivers Paraná and Uruguay.

Paraná, or Villa del Paraná, the capital of the province, is built on the south bank of the great river. The distance is 3° S. lat., 60° 47' W. long., and contains about 6000 inhabitants. It is built on the summit of a lofty cliff, which slopes gently towards Santa Fé, which stands on the opposite side of the river. The original name of the town is Bajada de Santa Fé, or, the 'Descent,' and the only public building of any consequence in Paraná is the recently erected government house. A large church which was commenced some years back remains unfinished. The climate is mild and healthy, and the town possesses two fire-places and all classes live much in the open air. The supply of water is very bad; all that is consumed is brought to the town in carts drawn by oxen. The town at present has a quiet, listless appearance. Only a few small vessels belong to it. The exports are hides, raw cotton, hides, and fish. The houses are mostly built of wood and mud, with thatched roofs. In the centre of the Plaza is a pyramid now falling to pieces. In the vicinity is a large saladero. Concordia, on the Uruguay, opposite Salta, from a village of a few mud huts, appears to be growing rapidly in population. It has about 6000 inhabitants, and carries on a good deal of trade. But the situation is bad, as vessels are unable to reach the town at low water, and are obliged to anchor about two miles below it. It contains a church and a large school-house, endowed by the SEC. of the province of Buenos Ayres. The name of the town is Concordia, of 2000 and 3000 inhabitants, of whom nearly 300 are foreigners, chiefly Basques and Italians. It is a place of a good deal of trade, but vessels cannot approach nearer than about three leagues from the town. In the neighbourhood is the most extensive estancia in this part of the country, belonging to an English subject. It is the property of Mrs. Britann of Sheffield, and occupies 300 square leagues of land. Several other estancias belong to English subjects, and are situated on the Bahía Blanca, near the mouth of the Gualeguay-chu, about 60 miles E.N.E. from Gualeguay, population about 2500, including nearly 300 foreigners, contains a neat church and a good school-house, and is a place of some trade; but the situation is inconvenient, as vessels drawing more than 6 feet of water are sometimes obliged to wait two or three weeks to get across the bar at the mouth of the river. In the neighbourhood are some large tallow-melting establishments.

EQUUS, a genus of Plants belonging to the natural order Polygonaceae. It has four thick and concave sepals connected together in a permanent uniovulate tube at the base, with three lobes at the tip. There is one petal, which is roundish, fringed, and inserted in the middle of the calyx. There are 10 stamens, which are long thickened filaments, rather villous at the base, and joined into a short monadelphous ring. The ovary is stigmatic. The style long and filiform. The legume compressed, dry, coriaceous, 4-valved, 1- to 4-seeded. When young it is tomato-shaped.

F. digitata is a tree with abruptly pinnate leaves, bearing 2 or 3 pairs of ovate acuminate shining leaflets. The peduncle is pendulous on a long peduncle, concealingly composed of numerous distinct racemes. It is the Wallaba-Tree of Guayana according to Sir Robert Schomburgk, who informs us that its wood is deep red, frequently variegated with white, hard, heavy, and shining, and impregnated with an oily resin which renders it very durable. The bark is bitter, and is used by the Arawak Indians as an emetic.

EPISTILITE. [MINERALOGY, § 1.]
EPISILLENITE. [MINERALOGY, § 1.]
EPISILLENITE. [MINERALOGY, § 1.]
EQUINE. [HORSE.]
EQUITY. The proceedings of the Courts of Equity have been greatly simplified and cheapened by several recent statutes and decisions. The first of these was the Act of the Commissioners appointed to examine this subject in 1860. Instead of the writ of subpœna, which merely gave the defendant notice of a bill having been filed but afforded him no information of its contents, the bill itself, in a convenient printed form, is now served upon the defendant, either personally, or by being left at his house; or under special circumstances with some other person (as for instance, the solicitor or agent of the defendant) as his substitute. In this event the plaintiff is not debarred against an unprivileged person, by having an attachment issued against him; against a privileged person, as a peer, or member of parliament, by a sequestration of his property; against a corporation, by a distinguo and sequestration if necessary. In the latter case another condition is that of proceeding by way of attachment and sequestration, he may enter an appearance for a defendant not appearing within eight days after the service, and thereupon proceed to judgment and execution.

Until the recent alterations, every bill in chancery contained what is called the interrogating part in which every statement and charge in the bill was converted into a series of questions, framed on the principle that the defendant might positively be a deceiver, and therefore suggesting modifications of the statement or charge. For example, if the statement were of a deed bearing a certain date, and made between and executed by certain parties in certain words, or to a certain effect, the questions would be, whether such a deed of that date, or of some other and what date, was not made between and executed by such parties, or some and which of them, or some other and what parties, in such words, or to such effect, or in some other and what words, etc. Now in most cases such interrogatories were used much more sparingly, and were confined to those matters supposed to be within the knowledge of the defendant, as to which it was considered necessary or desirable to extract admissions from him. But in the great majority of cases the rule of procedure in chancery was adopted of transmitting all the statements into questions of the nature above described. The length of the proceedings and the expense to all parties concerned were thereby greatly increased. There is now no interrogating part in any bill: but where the plaintiff requires an answer from any defendant or defendants to a bill, he may file interrogatories for their examination.

The demurrer, plea, or answer of the defendant to the bill, each remaining as before, — except that the answer is no longer taken with the expensive formalities which used to accompany it. Formerly a declimus potestatem or commission was issued to take the answer and oath of a defendant in the country, which was sealed up, and either sought by one of the commissioners to the court, or sent by a messenger, who swore he received it from one of the commissioners, and that the same had not been opened or altered since he received it. The answer is now however filed without further formality than in ordinary pleading, being affidavits, and not necessarily before any judge, court, notary public, consul, or vice-consul, lawfully authorised to administer oaths, the messenger's oath being dispensed with.

In many cases, indeed, when the facts in dispute between the parties are simple, and not of a complicated character, an answer is not now requisite. Affidavits may be filed by the plaintiff and defendant, upon which the Court will determine the case, unless it be thought proper, in addition thereto, to examine or cross-examine the parties orally.

The practice which formerly prevailed of examining witnesses on interrogatories, having been found in many respects very inefficient and objectionable, has also been abolished; the court retaining the power to order particular witnesses to be examined upon interrogatories, even at the request of the parties. When therefore a suit commenced by bill is at issue, the plaintiff may give the defendant notice of the mode in which he desires the evidence to be adduced, namely, orally or upon affidavit. And if the parties give no such notice, requiring such notice, he expresses his desire that the evidence be adduced upon affidavit, then both plaintiff and defendant may verify their respective cases by affidavit, unless the defendant gives notice to the plaintiff that he desires the evidence to be adduced orally, and if no such notice is taken, the witnesses are examined by or before one of the regular examiners of the court, or an examiner specially appointed if necessary. The principal defect in the old mode of examining witnesses, was, that the examination being conducted in the same manner, the party cross-examining laboured under the disadvantage of not knowing what the witness had deposed in his examination in chief; under the modern system, the oral examination of witnesses takes place in the presence of the parties, their counsel, solicitors, or agents;
and the witnesses are then and there subject to cross-examination and re-examination. Every deposition is taken down in writing by the examiner in the form of a narrative, and read over to the witness, and signed by him, in the presence of the parties. When concluded, the examiner transmits the deposition to the Court, and the cause is then ripe for the hearing.

Another important change in equity procedure relates to the determination of questions of law, as distinguished from equity. The practice in equity, on the introduction of a cause of action, was the practice of the Court to refer it to the opinion of the judges of the Courts of Common Law, upon a case stated for that purpose; who certified their opinion to the chancellor, upon which certificate the decree would be made. This must now itself determine any questions of law which require to be decided previously to the decision of the equitable question at issue between the parties; for which purpose any of the courts may obtain the assistance of the judges of the Court of Common Law.

A shorter and simpler method of proceeding than that by Bill and Answer was introduced in the year 1850, namely, that of Claims. This plan was only intended to be used in certain definite cases of comparative simplicity; and subsequent legislative enactments have so much improved the mode of proceeding by Bill, that the advantage of having recourse to a Claim is not now so great as when that procedure was first introduced, and in many cases a Bill according to the new system is found to be far preferable. Claims are introduced in the form of Bills, with all the merits of which are to be decided upon affidavits on each side; every order made on the hearing of which has the same effect, and may be enforced as a decree in a suit commenced by Bill. The claims are to be verified, or set aside upon motion; and any order of the Master of the Rolls, or any of the Vice-Chancellors, may be discharged or varied by the Lord Chancellor or the Court of Appeal in Chancery.

Another more summary method of proceeding has been introduced, by the statute 15 & 16 Vict. c. 86, applicable to similar cases of administration. Any person claiming to be a creditor, legatee, or next of kin of a deceased person, may obtain a summons from the Master of the Rolls or any of the Vice-Chancellors, requiring the executor or administrator of the deceased person to attend and show cause why an order for the administration of the estate of the deceased should not be granted.

Upon proof of the due service of such summons, or on the appearance of such executor or administrator, and upon proof by affidavit of such other matters, if any, as the judge shall require, the judge may make an order for the administration of the estate of the deceased, with such variations, if any, as the case makes: such an order has the effect made to have the force and effect of a decree of the like effect made on the hearing of a cause or claim between the same parties.

Any such order may also be filed, in order to obtain the opinion of the Court upon the decision of any question under Sir George Turner’s Act, 13 & 14 Vict. c. 35; but as the Court can now make a merely declaratory decree, under 15 & 16 Vict. c. 86, the same end may be more conveniently obtained, in most cases, by short Bill without interrogatories.

These are the principal alterations in the procedure of our Courts of Equity; some minor details of practice in which changes have been effected, it would be out of place to enlarge upon.

ERICSSON, JOHN, Engineer, a native of Sweden, but whose inventions have been brought before the scientific world in England and America, was born in the province of Vemeland in 1803. In 1814, by the friendship of Count Platen, who observed his mechanical tastes, he obtained a cadetship in a corps of Engineers. He subsequently entered the regular army as an ensign, and at length reached the rank of lieutenant. In 1826 he visited England in order to bring into practice a new kind of engine which he had invented, and which had hitherto been used, in Europe, in the production of hot steam, and therefore could not work without the dissipation of flame. The project failed from the impossibility of procuring suitable fuel for the engine. He competed for the prize which was offered by the Liverpool and Manchester Railway Company, in 1829, for the production of the best locomotive, and presented an engine which worked at the rate of fifty miles an hour. Ericsson’s subsequent career lay chiefly in America. In the Great Industrial Exhibition of London in 1851, several instruments for the measurement of distances at sea, for measuring fluids under pressure, and other similar purposes, appeared in the American department under Mr. Ericsson’s name, and were described by him in a small work which he issued at the time. His name is chiefly connected with a project for the generation of steam which was to supersede steam, an object which, if accomplished would, by removing the necessity of carrying large cargoes of fuel, have effected a great commercial change in the intercourse between distant parts of the globe. At the time the project was introduced, Ericsson was a citizen of Sweden; but on her return she was struck by a squall, filled, and foundered close to the city of Jersey. The Ericsson was subsequently raised, and the caloric engine was replaced by the ordinary engine, whichBursick approved of by Mr. Ericsson. Mr. Ericsson was a member of numerous scientific societies and a knight of the Swedish order of Vas.

He died on the 2nd of November, 1853.

ERLITE. [Mineralogy, &c.]

ERROL [Pertinaxes].

ERROR, IN LAW. The mode of appealing from the judgments of the Courts of Common Law to the appellate tribunals constituted to rectify their mistakes by bringing up the error of the decision to the courts of appeal by the Common Law Procedure Acts of 1855 and 1854. These statutes have abolished writs of error in civil suits, and substituted for them a simple notice or memorandum of the errors found, and appeal is made to the Court, of the appeal having been made. The statutes have likewise extended and in so doing improved the jurisdiction of the Courts of Error. Formerly judgment could only be affirmed or reversed; but the Court of Error may now give the judgment which ought to have been given by the Court below, and award all necessary process for giving effect to it.

ERYTHACA, a genus of Birds belonging to the family Syriniæ, the order Aves, having the following characters:—Beak rather broad and depressed; nostrils close to the base, coming almost in a downward direction to the point, slightly constricted; upper mandible deflected and notched. Notostilis basil, lateral, oval, pierced in a membrane partly hid by feathers and hairs projecting from the base of the beak. Wraps rounded; the three exterior quills graduated; the first only half as long as the secondary, which is shorter than the third; the fourth, fifth, and sixth longer than the third; the fifth the longest in the wing. The tarsus longer than the middle toe; the toes nearly equal to each other in length; the second the longest; the claw of the hind toe longer and stronger than the others.

E. rubecula, Sylvia rubecula, Motacilla rubecula, the Robin Red-Breast, Robin-Redstart, Robinette, Duddock, is so generally distributed over the European countries, divers other countries, where all are sufficiently interested in the bird to make themselves acquainted with its habits. These may be observed in any garden, field, or wood, for there is scarcely a hedge without its Robin inhabitant, and if Robbins appear to be more numerous in winter than in summer, it is partly owing to the state of vegetation at the former season, which leaves them more exposed to observation, and partly because they resort to the habitations of men for food, when other means of supply fail. The song of the Robin is sweet but not very melodious, and Mr. White of Selborne says, 'The Robin sings all through the year. The reason that he is called an autumn songster is, because in the spring and summer his voice is lost in the general chorus, while in the autumn it becomes distinguishable.'

The Robin, one of the latest birds to retire to rest, and the earliest to be seen moving in the morning, requiring apparently but little sleep.

This bird is very easily tamed, soon becomes familiar with those who feed it, and constantly builds its nest in place frequently frequented by man.

Mr. Blackwall relates that a pair of Robins built their nest in a small saw-pit. Soon after the hen had begun to sit the sawing of timber was commenced at this pit, and though she was carried on every day close to the nest during the hatching of the eggs and rearing of the young birds, the old birds exhibited no signs of alarm or interruption. These birds exhibit great attachment to each
other, and many instances have been related to prove that they pair for life. With all his interesting qualities the Robin is not amorous; and not only maintains his right against all intruders, but is said to kill those of his own family when they become troublesome to him. Robins breed early in the spring. The nest is composed of moss, dead leaves, and dried grass, lined with hair, and sometimes with feathers; it is usually placed on a bank sheltered by bushwood, or a short distance above the ground in a thick bush or lane hedge, sometimes in a hole of a wall partly covered by ivy. The eggs are from five to seven in number, and of a white reddish-brown; the length nine lines and a half, by seven lines and a half in breadth. The bird is found all over England, Ireland, and Wales; it is also an inhabitant of the most northern counties of Scotland. It also visits Denmark and Sweden in the breeding season; and so well does it bear cold weather, that among the summer visitors to the latter country, the Robin is one of the first to come and the last to go.

It is a constant resident throughout the year in all the temperate and warmer parts of Europe, abundant in Spain and Italy, Sicily and Malta.

In the adult bird the beak and irides are black, upper part of the head, neck, back, upper tail-coverts, and tail-feathers, a yellowish olive-brown; tail-feathers rather darker, the outer ones with the edge of the secondaries tipped with buff, over the base of the beak, round the eye, the chin, the throat, and the upper part of the breast, reddish-orange; encircling this red is a narrow band of bluish-gray, which is broadest near the shoulders; lower part of the breast and belly white, the flanks and under tail-coverts, pale brown; under surface of wing and tail feathers dusky gray; legs, toes, and claws, purple brown. The whole length of the bird is 6½ inches. The female is not quite so large as the male, and her tail is slightly shorter, but the sharp points of her tail-feathers is very easily discernible.

The Red-Breast is subject to variation in the colouring of the plumage. White and partly white varieties are not uncommon. (Yarrell, British Birds; MacGillivray, Manual of British Birds.)

Erythr ... [In 1787.]

His father rented a mill in the suburbs, and kept a baker's shop in the city; and the boy assisted in the shop till he was of age to put to be a trade. He had already shown a marked fondness for drawing, and his mother, as in after-life the great painter was fond of relating, had encouraged his propensity, while neighbours used to 'patronise' the inconstant artist with halfpence and pennies to buy chalk and pencils. In his twelfth year he was apprenticed to a painter at Hull, in which situation, over-worked, without friends and distant from his family, and denied the privilege of drawing, he appears to have at first led a very uncomfortable life. But after awhile his master was persuaded to let the boy 'at lawful hours' indulge his artistic tastes, and, though still without instruction, Etty soon began to acquire sufficient facility in drawing to make his companions in the painting-office desirous to possess, and some of them careful to preserve, his sketches and rude attempts at painting. At length, when seventeen years of age, he left his master and obeyed the invitation of an uncle to come up to London.

His uncle, himself a skilful draughtsman, saw promise in the youth's crude efforts, and generously afforded him the means of practically solving the question whether his art was a calling or not. His patronage was an impulse merely, or the result of a native aptitude.

At first, without any formal instruction, he drew, as he says in his 'Autobiographical Sketch,' 'from prints, or from nature, or from anything he found; by order of the academy being a plaster-cast shop, kept by Gianelli, near Sotheby.' Having thus sufficiently mastered the difficult
Ett. 220. Eun.

After this great success Etté resolved again to visit Italy, and though he be this time also carried with him a new love sorrow, he did not suffer himself again to return without seeing Rome. There, and at Venice, where he stayed seven months, he laboured with a diligence and copied with a rapidity and decision of execution, which astonished the dealers in his works, who sold his entire stock of pictures of being purchased by the President, and procured his election as Associate of the Royal Academy. "Strike while the iron is hot; you see what may be done by a little courage," was the advice now tendered by his old master, and Etté profited by that counsel. His works followed, some of large size and in the historical style, but mostly classic subjects of the order indicated above, and each succeeding one,—until he became careless or negligent under the pressure of competing patrons claiming ever and pictures from him,—contributing its share towards placing him in the position he ultimately obtained by general consent of the first English colourist of his day, and also by far the first English painter in his own peculiar walk of any day. The little pictures were one or two entirely spent in London and in his painting-room—the only breaks being an occasional visit to a friend in the country, a run to Edinburgh or to the Netherlands, and a brief stay on account of illness at York. His evenings he passed, during the winter months, laying aside the most invaluable works for the Royal Academy, where to the last he was one of the most regular and diligent among the students—it being his practice to paint studies in oil from the living model as shown them by his greatest masters, and to invariable Lemprière's Dictionary—ought to have his deficiencies in every kind of intellectual culture, except in the techniques of painting, of course militated against his taking a first rank as a painter of classical themes. All his works evince his own great and constant effort; but his mind had been trained as well with the poetry of Greece and Rome. But, allowance being made for these deficiencies, or rather regarding his pictures as the mere vehicles for the exhibition of the undraped human form, his painting must be adjudged high place in comparison with those of any other modern painter.

To the highest order of female beauty either in face or form he never attained—hardly pretended; yet there is a certain grace and beauty in his work of enjoyment, so much life and heartiness, and looking at them as pictures, there is shown so remarkable a knowledge of the female form, and such facility in rendering it in free spontaneous action, as few if any modern artists of any country have equalled, and none even in olden times surpassed.

Etté towards the close of his life seems to have become especially disturbed by the strong remarks occasionally made on his choice of subjects, and still more on his mode of treatment. He seems to have thought (and his admirers have spoken as though they thought so too), that the objections raised to so free a display of the female form on the score of morality, was in fact an implication that the painter was either an insolent rake, or an object of ridicule, or one who knew anything of the painter. Few men in private life have given less occasion to the breath of scandal. He was scrupulously upright, sober, and pure. An artist whose confirmed proclivities were those of men; but it was not to be wondered at that the painter of works so opposed to the current notions of propriety should have had to bear with some hard judgments on the tendency of his works. He sought to vindicate himself and his intentions with his pen as well as his tongue, but while personally he needed no vindication, the only vindication his pencil can receive must be that which the works themselves furnish.

EUCHRIOTE. [MINERALOGY, S.1.]

EUGENINE. [CHEMISTRY, S.2.]

EULIMELLA, a genus of Molusca belonging to the family Pteriomidae, founded by E. Forbes, of a number of forms that had been previously referred to Eulima and Odostomia. The shell is elongated, and consists of many whorls, solid, smooth, and polished; the apex of the shell has a persistent embryonic spiral shell; the aperture subquadrate; periostracum smooth, thick, and yellow; and the muscle scar is the operculum corneous, pyriform. There are four British species. E. sella (Eulima crassula, Jeffrey), E. oculata (Melania oculata, Philippi), E. affinis (Eulima affinis, Philippi), E. clavata (Eulima clavata, E. fuscata (Eulima fuscata, E. clavata (Eulima clavata, Linn.)

EUNICE, a genus of Dorsibranchiate Annelida. It is furnished with tuft-like gills; the trunk is armed with three pairs of horny jaws; each of the feet has two cirri and a
bendle of bristles; two tenacula upon the head above the mouth, and two on the neck.

_Eupatorias_ is the largestANNELIDE known. It attains a length of from one to four feet, and inhabits the sea around the Antilles.

EUPATORIA, previously named _Kosloff_, a seaport town in the government of Taurida, on the west coast of the Crimea, is situated on the north shore of the Bay of Karalitsa, in about 45° 14' N. lat., 33° 25' E. long., 40 miles N.W. from Simpheropol the capital of the Crimea, and 45 miles from the port of Odessa. According to the census of 1851 it was 2,920, chiefly Tartars and Karakit Jews, with a few Greeks and Armenians. The port is shallow, admitting only vessels of about 8 feet draught, but tolerably safe and never frozen up. The bay forms an estuary. The trade is carried on by coasting vessels and ships which may approach within cable's length of the shore, but it is exposed to the west and south winds which cause a heavy surf all along the coast. The town, which is surrounded by an old crumbling wall, is ill built; the streets are narrow, crooked, and dirty; the houses, low and built of bricks and clay, open upon courts or gardens in the Turkish fashion, but present to the street only low dead walls. The principal buildings are a Russo-Greek church, several mosques, an Armenian church, two pretty synagogues, and a very fair wool factory.

The town is famous for the preparation of the black lambskin, known in England as 'A black' at a halfpenny a skin. The sheep are reared in villages and slaughtered in the vicinity. The skin is cured, brushed, and there are more than 100 manufacturers of this product. In 1841, there were 100,000 skins, and in 1842, 120,000, the value in 1842 being estimated at more than 100,000 rubles.

Eupatorias is the capital and chief town of the ancient _Eupatoria_, or _Eupatirion_, founded by Mithridates Eupator, and named after him. This town is now called Eupatoria, and there is no proof that the two places are identical. Some authors say that the site of the ancient Eupatoria is marked by the village of Inkerman on the north shore of the Bay of Sebastopol, where there are ancient ruins. It is possible that this town may have been the same as Eupatoria, but this is not certain.

Eupatoria was annexed to the Taurida Governorate in 1861. It has a population of about 12,000, of whom about 5,000 are Russian, 3,000 are Crimean Tatars, and 4,000 are Greeks. The town is connected by rail with Odessa and Simpheropol, and has a good harbor for small vessels. The chief products are hides, wool, and skins. The town is famous for its black lambskin, which is exported to Russia and other countries.

Evénement. [Mineralogy. S.1.]

**EVIDENCE.** Great and important changes have been made during late years in the Law of Evidence. Not only have the means of obtaining and producing evidence been simplified, and facilities in doing so afforded to the suitor; but all the former disqualifications of the parties to and of the persons interested in the result of the proceedings have been entirely removed. The most important practical improvements have been in our Courts of Common Law, the want of a complete discovery by the oath of the parties having formed till recently one of the greatest and most prominent defects in the procedure of these courts. The challenge of evidence, that is, the right of the parties to have such a discovery, by going through the expense and circuity of a Court of Equity, and therefore it was sometimes had by consent, even in the courts of law. But as it had long been established in our Courts of Equity, and as it seemed to be the rule of judicial approach and aid to the parties, to have such a discovery, by going through the expense and circuity of a Court of Equity, and therefore it was sometimes had by consent, even in the courts of law. But as it had long been established in our Courts of Equity, and as it seemed to be the rule of judicial approach and aid to the parties, to have such a discovery, by going through the expense and circuity of a Court of Equity, and therefore it was sometimes had by consent, even in the courts of law.
of our former law have been gradually relaxed by a series of modern statutes. The first inroad on the systematic exclusion of evidence, which was the result of the former state of the law, was made by the statute 3 & 4 Will. 4. c. 42, s. 96, which has been already mentioned, and is only again referred to in the subsequent text. The effect of this act was to allow that, in order to render the rejection of witnesses on the ground of interest less frequent, if any witness should be objected to as incompetent, on the ground that the verdict or judgment in question was prejudiced by his testimony, in the event of his being found for or against him, he should nevertheless be examined; but in that case the verdict or judgment should not be admissible for or against him, or any one claiming under him. A much greater improvement was, however, effected by the act 17 & 18 Vict. c. 83, which removed the ground of interest in all persons, except the parties to the suit, or the persons whose rights were involved therein, or the husband or wife of such persons. The advantages found to flow from this alteration in the law led to the statute 14 & 15 Vict. c. 99, by the first section of which the proviso in the statute 6 & 7 Vict. c. 85 (which excluded all persons directly interested in the suit) was repealed. By the second section, the parties are made competent and capable of giving evidence on behalf of either or any of the parties to the suit in any court of justice. The third section of the statute provides that it shall not render any person charged with an offence competent or capable of giving evidence against himself or any party or anyone who has given evidence tending to criminate himself, nor shall it in any criminal proceeding render any husband competent or capable to give evidence for or against his wife, or any wife competent or capable to give evidence for or against her husband. The proviso in the former provision of the statute that it shall not apply to any proceeding instituted in consequence of adultery, or to any action for breach of promise of marriage, was deleted, soon after it had become law, that the second section of the statute did not render a wife admissible as a witness for or against her husband, and accordingly the statute 16 & 17 Vict. c. 83, was passed, enacting that the husbands and wives of the parties to any suit, or of the persons on behalf of which any such proceeding is brought or defended, shall be excluded from testifying as witnesses, save only in any criminal proceeding or in any proceeding instituted in consequence of adultery. By these several statutes all rules tending to the exclusion of evidence have been abrogated, except in the particular instances above mentioned. (Blackast. 'Comm.' Mr. Kerr's ed. 30.)

EXCELMANS, REMI-JOSEPH-ISIDORE, BARON, Marshal, was a native of Bar-le-Duc, where he was born November 13, 1775. He entered the army very young, and first directed attention to his services, in 1799, whilst under General Oudinot, commanded in the Netherlands, and captured the fortress of Loo. In 1800 he became aide-de-camp to General Brossier; but exchanged that for the same post under Murat. At the combat of Wurtingen, on the Danube, October 6, 1805, he had three horses killed under him; and being commissioned to lay the numerous flags taken from the enemy at the feet of Napoleon I., he received from the hands of the emperor the decoration of officer of the Legion of Honour.

In 1806 he was made colonel of the first regiment of Chasseurs, and was mainly instrumental in the capture of Posen, in Poland. He was afterwards engaged at the doubtful battle of Eylau, and for his conduct in that action (1807) he was appointed to command a brigade, and placed on the staff of Prince Murat, where he afterwards accompanied him to Spain. It was General Exelmans who was commissioned to head the escort by which King Charles was attended to Bayonne, after he had been induced to abdicate in favour of his son. On his return, General Exelmans was arrested, with other officers, and sent to England, where he remained a prisoner until 1811. On his release he again joined his former general, who had ascended the throne of Naples. Soon after, in 1812, in Junot's corps, as second in command, he was several times with a general of division, September 8, 1812. Savary, in his 'Memoires," ascribes entirely to Exelmans the merit of saving the remnant of their corps, which returned home after that arduous campaign.

In 1813 his division was placed under the orders of Marshal Macdonald; he took an active part in the operations in Saxony and Silesia, and was rewarded with the cordon of great officer of the Legion of Honour. In 1814 he commanded the cavalry of the Imperial Guard, and was present at many of the battles fought by Napoleon to defend the French territory. After the return from Elba, General Exelmans was called to the Chamber of Peers, June 3, 1816; and despatched to join the army of the north. He was not present at Waterloo, but took the command of the troops that were back in his division to the walls of Paris, in time to defend the capital, and to check the advance of the Prussians, whom he defeated at Vernailles in the last action of the war. Exelmans was included in the decree of July 18, 1816, and banished for life from France; but he reached, with honours, the bridge of Savres. He never spoke afterwards, and expired at two o'clock the next morning. (Rabbe; Savary, 'Memoires'; Bigot des Contemp.; Dictionnaire de Conversation.)

EXECHEQUER. [GREAT.] The Court of Exchequer in Scotland has been abolished by the statutes 19 & 20 Vict. c. 56; and its jurisdiction, under an amended procedure, transferred to the Court of Session. This court was instituted with the object, carefully concealed however, of introducing into use in Scotland the Common Law process peculiar to England, by means of the writ of quo minus. Had this been effected, the legal procedure in both countries would probably by this time have become entirely assimilated. The first conviction of a criminal in Scotland by a jury was, however, met by an assertion on the part of the Court of Session, of an authority to confine the jurisdiction of the former Court to matters of revenue, which being submitted to the writ of quo minus became useless for its intended object.

EXCRETIN. [CHEMISTRY, S. 2.] EXECUTION. [ATTACHMENT OF DUTIES, S. 2; DETINUS, S. 2; GOOM, S. 2; EXCISE, S. 2; EXCELSIORS, S. 2.] EXHIBITION OF 1851. The great Industrial Exhibition of 1851 was in itself an event of so much importance, one which excited such very general interest, and has been the parent of so many other exhibitions of a somewhat similar character in the different countries, that—without entering upon the larger question of its immediate or remote influence upon manufacturing art and skill, or commercial enterprise—it may be useful to present in this work a brief summary of facts and figures illustrative of the history of the undertaking.

There had been industrial exhibitions in England and on the Continent, but they had been of a more or less local character, or at the utmost confined to the manufacturers of one country in which they took place. In England there had been the Exhibition of 1814, an exhibition of industrial art and industry resembling the well-known Paris exposition. The proposition for a great exhibition of national manufactures to be held at intervals of three or more years seems to have originated in 1845 with the Society of Arts, London, of which Prince Albert was president. On its first announcement the project was coldly received, and some three years were suffered to elapse before it was again brought distinctly before the public. Meantime the annual exhibitions of the society had gained more attention, and it was by the more alert and commercial men began to feel increased interest in the proposal. By the beginning of 1849 the council of the society had matured a plan, of which in March of that year an exhibition was established on the site of the south-western parliament for pecuniary aid. Prince Albert, who had all along warmly supported the proposal, conceived that the time had arrived for imparting to it a much more magnificient form, by throwing the exhibition open to the industry of the
The council adopted his suggestion, and measures were taken for enlisting in behalf of the scheme the sympathy of the Lord Mayor and of the Corporation, and then those of every other nation. The idea of an International Exhibition of Industry at once seized the general mind. At the preliminary meeting held in the city under the presidency of the Lord Mayor, the council consulted for time and again on the plan of the exhibition, and was at length resolved to carry the scheme, it was received with the utmost favour, and the provinces speedily gave in their cordial adhesion. The Council of the Society of Arts, which in the first instance assumed the direction of the Undertaking, entered into negotiations with a private firm, Messrs. Munday, who were engaged to deposit a sum of 20,000£ on the 30th of August, 1849, and to provide whatever additional money might be required between that time and three months after the final closing of the account of the subscription list. On the 12th of September 1851, the opening of the exhibition building was in the first instance estimated at 20,000£, but Mr. Cubitt on being consulted by Prince Albert named 60,000£, as a far more probable sum—so entirely at sea were the projectors of the scheme as to its extent and the amount of money required to carry it into effect.

Upon the suggestion of Prince Albert, application was made to the government for the appointment of a Royal Commission for managing an Exhibition of the Works of Industry of All Nations, and the ordinance was duly issued in January 1850 appointing such a Commission with Prince Albert as its president. At the first meeting of the Commission, the contract entered into with Messrs. Morrison, which had been home the building, was annulled, and eventually a sum of 51,000£ was awarded to the contractors as compensation for their probable loss. The Commissioners now appointed (January 24) a Building Committee, to whom was entrusted the entire arrangements for the building of this, the greatest part of which was completed by the 1st of January 1851, at which the city of Hyde Park, at which the hearty adhesion of various influential merchants and manufacturers was announced, and a general subscription was inaugurated with a view to raising funds for meeting eventual expenses. It was followed by corresponding meetings in every part of the country, and it was soon made evident that ample funds would be furnished. In fact a total of very nearly 80,000£ was ultimately reported to the Commissioners as subscribed, though only 67,600£ was paid into their banks—upwards of 11,000£ having been somehow absorbed in the several localities as expenses. On the 21st of February, the Commissioners were able to make a public announcement of the general undertaking, and to communicate the Royal permission to hold it in Hyde Park.

The site granted for the building was on the south side of Hyde Park, between Kensington Drive and Rotten Row. The Commissioners announced that the building would cover an area of 50,000 square feet, and that it would contain the reception of goods by the 1st of January, 1851; that from day to day of March following goods would be received, and that the Exhibition would be open to the public on the 1st of May, 1851. In March 1850 the Building Committee appealed to architects and engineers to assist them with sketches and suggestions as to the form and general arrangements of the building required for the Exhibition. This appeal was responded to by a large number of professional men, including several foreign architects. In the course of May the Commissioners announced that they had examined the 243 designs sent in, but though several were of sufficient excellence to obtain special commendations, they were unable to select any one design on account of the difficulty of judging the nature of the undertaking. Of the designs sent in 18 were however singled out by the Commissioners for special commendation, and it was noticed as a curious circumstance that, though only 28 out of the competing architects were foreigners, of the 18 who were, all chosen only three were natives of the United Kingdom. However, though unable to recommend any one of the designs for adoption, the Commissioners stated that they had derived much valuable suggestion from the plans to guide them in preparing a design for the building, which they laid before the Commissioners, a building was proposed which was to be 2300 feet long, 400 feet across, and to cover upwards of 20 acres. It was to be constructed of brick and lighted by sky-lights. In length it was divided into a grand central hall, in shape a polygon of 16 sides, the main walls, which were to be of brick, being carried up to a height of 60 feet, and it was to be covered with an iron domical roof, much larger than any hitherto constructed, being 300 feet in diameter, and of 200 feet high, with stonework of St. Paul's, and 48 feet larger than that of the Pantheon of Rome. The report of the Building Committee gave general dissatisfaction in various ways, but their design—so obviously prepared for being carried out with some degree of disapprobation. For awhile the whole scheme seemed in peril, when Mr. (now Sir Joseph) Paxton came to the rescue by proposing an entirely new plan, that of a vast building of iron and glass resembling in its general principles the great conservatory constructed for the Duke of Devonshire at Chatsworth. Having powerful influence, he was enabled —though at this late hour when tenders had been publicly invited for the committee's design—to obtain permission to carry out his plan, and it was decided by the committee to proceed with it. Its singular adaptation to the purpose of the Exhibition as well as the great comparative facility with which it could be erected and removed, at once commanded their approval. With the general public it from the first became popular, and as soon as the contractors, Messrs. Fox and Henderson, undertook its erection upon terms which removed all doubt of its economy as well as practicability, the Commissioners determined upon adopting it, and accepted Messrs. Fox and Henderson's tender. They were to receive 79,800£, the materials for the building remaining the property of the contractors.

From this time all proceeded rapidly and smoothly. The contract was signed on the 26th of July; on the 30th the contractors obtained possession of the site; on the 26th of September the building was almost ready to be begun; and on the 4th of December the first rib of the transept was raised; by the 31st of December the building was sufficiently advanced to allow of a lecture being delivered within it to the members of the Society of Arts, and on the 3rd of February, 1851, the complete building was formally handed over to the Executive Committee.

The form and character of the building are too well known to need any detailed description. It will be enough to say, that its entire length was 1851 feet—its breadth, 408 feet, with an additional area of 718 feet on the north side, and 484 feet by 48 wide. The central portion was 120 feet wide by 64 high; on either side of this was another portion 73 feet wide by 44 high; and the north and south portions were 73 feet wide by 24 high. The portions or great avenues here described ran east and west through the building; very near the centre the transept crossed, with a width of 72 feet and a height of 108. The entire area was 772,784 square feet, or about 19 acres—nearly seven times as much as St. Paul's. The windows were arranged in double pairs, and opened into a central nave, four side aisles, and several exhibitors' courts and avenues. There were 3 entrances, with 8 pay places to each, and 18 doors for exit. Four galleries ran lengthwise on either side of the building, and others around the transept; and access was given to them by 10 double staircases. The iron columns in the building, which, with their connecting pieces, were about 20 and 24 feet high respectively, were about 3300 in number; and there were 1074 base pieces beneath the columns, on which the whole structure rested. There were nearly 3500 girders, of three different lengths, 24, 48, and 72 feet, and of five different weights, 13, 13, 35, 130, and 160 cwt. Altogether there were about 4000 tons of iron built into the structure.

In the woodwork for the glass roof, the Paxton girders were 8 feet apart, with a ridge between every two. The squares of glass were 49 inches by 10. Besides the 17 square meters of glass (the freshest meters of glass court) there were about 1500 vertical glazed sashes. The ground floor and the galleries contained 1,000,000 square feet of flooring. Of sash bars there were 200 miles, and 30 miles of Paxton girders. The total woodwork in the building was estimated at 100,000 cubic feet. The form of the columns and girders was the same throughout, so that of the sash-bars, so likewise was the size of the panes of glass. The structure itself was built up of a series of bays or cubical compartments, each 24 feet square; each was left unlighted and then filled out as required. The commonest girders very ingeniously put together. Thus the entire ground-plan may be regarded as a series of these squares, the parallelism being 77 of them in length and 17 in width—total 1307 of them. The Paxton girders substituted to form the nave, courts, and transepts. The additional portion on the north side of the building was
30 of these squares long and 2 deep. The whole building, in fact, from the ground-plan to the ridges of the roof, was a repetition of the main regular format; and, in proportion, had the grandeur of a first thought, as most models of simple arithmetical calculation, and consequently from the hour when the contractors commenced their work, from the simplicity of the plan and the singularly small number of casting and other works, was practically a skeleton, each member of the whole framework of the edifice with the three principal colours, blue, red, and yellow, "in such relative proportions as to neutralise or destroy each other." Of course the announcement of his system was met with much depreciatory criticism, but the result amply justified his predictions. It was admitted that the colour added much to the general effect of the building, while it harmonised well with the contents. How admirably the building answered its purpose, what new and elegant combinations of form, light, and shade and colour, both the exterior and interior offered to the eye, or what a magnificent and surprising appearance it presented as a whole, whether regarded externally, or when, looking down its unrivalled vista, with its rich and varied contents, from lofty archways, pavements, roofs, and walks, as to the present under way, as to ever to be described. As is well known, the building has been re-erected at Sydenham as a permanent structure, with great improvements on the original aspect.

As soon as provision had been made for the building, the Commissioners turned their chief attention to the means necessary for obtaining its contents. The outline of an elaborate system of classification, drawn up by Dr. Lyon Playfair, was issued, showing what a wide range of articles was sought to be brought together under the title of "Objects of Industrial and Productive Art." The whole was arranged under four great sections: Raw Materials, Machinery, Manufactures, and these were divided and subdivided into a vast number of classes and sub-classes. To facilitate the collection of the objects, and to serve as ready means of intercourse between the producers and the commissioners, district committees were formed in all the principal towns and manufacturing localities, by whom all the arrangements respecting the allotment of space in the building and the transmission of the goods were conducted. Formal communications were made to the various foreign governments as well as to the governors of British colonies, by means of official despatches ordered to be conducted the operations in those countries required for their adequate representation in the great undertaking. And so judicious were these several arrangements, that though from almost every country of Europe—from the North American Union—from the republics of South America—from each of our own wide-spread colonies—from India, Egypt, Persia, and even from the Society Islands, specimens more or less bulky, valuable, and numerous were sent, the numbers comparatively few that reached their destination material late than the date at first fixed for their arrival. Considering the entire novelty of the whole proceeding, the immense difficulty there must have been in many instances experienced in getting the collections together, the little knowledge that a large proportion of the contributors could have had of the extreme importance of punctuality, as well as their comparative want of interest in the success of the scheme, and the various physical as well as conventional obstructions which had to be encountered, this must, we think, be regarded as by no means of the least remarkable circumstances connected with the successful issue of the whole.

Of the actual number of objects purchased and record was kept; and as often a large number of articles was included under a single entry, no close approximation was, perhaps, possible. The Jury Council, however, in their report to the Royal Commissioners, said that the duties of jurors had "admitted the very greatest number of articles; at least 50,000,000 articles;" but this, though it tells much for the zeal and industry of the jurors, does not do anything towards explaining how the units of the million were determined. Of the whole amount contained in the building, making all guesses were hazarded during the vicissitudes of the Exhibition; the Commissioners state in one of the appendices of their Report that, taking in each case the owner's estimate of the value of his possession, the gross value of the articles exhibited—the famous Koh-i-nor diamond being accepted as the record—was worth £1,581,000, or about £7,802,901. 11s. 4d. The total number of exhibitors was about 10,000.

The Exhibition was formally opened by her Majesty, on the 1st of May, 1851; it remained open 144 days, being the longest period of any public institution in London. The entire number of visitors paid to the Exhibition was 6,063,998, being a daily average of 42,111. This average was not reached till June, but from that time till the close of the Exhibition there was comparatively little variation till the last week when the average again rose to the number of the visitors during this week was so extraordinary that we are tempted to set down the figures in detail. Monday, October 6th, 107,316; Tuesday, 109,915; Wednesday, 109,760, Thursday, 90,913; Friday, 40,313, Saturday, 53,061. The following are the principal contracts presented by the daily returns: Highest for all beverage, May 24th, 44,512; Lowest, July 19th, 9,327; Highest half-crown day, October 11th, 53,061; Lowest, September 6th, 15,672; Highest shilling day, October 7th, 109,915; Lowest, May 26th, 25,408.

The six million visits paid to the Exhibition plainly indicate but very roughly the actual number of visitors. Some persons went doubtless ten or even twenty times during the season, a very large proportion went twice. After weighing therefore the percentages that have been arrived at, and bearing in mind the result arrived at the conclusion that the probable average of visits would be about three, and that consequently about two millions of persons visited the Exhibition. Further, an attempt was made to ascertain the approximate number of foreigners; a few of the lists furnished to the Home Office by the captains of all steamers plying between the ports of England and the continent of Europe, and of returns furnished by the United States Legislation, from which it appeared that the total number of aliens who entered England from the United States from the 1st of April and the 30th of September, 1851, was 58,427; a number very far below what the public imagination had supposed. During the same period in 1850 the number of aliens who landed in England was 15,514, so that 42,913 would seem to be the ultimate number that has to be supposed to have visited this country for the express purpose of seeing the Exhibition, though probably few of the remainder left these shores without visiting it. The largest number of visitors was from France, 37,575, then came Germany, 10,400, the United States, 5000, Belgium, 3700, Holland, 2900. But if the numbers be considered in relation to the population of the several countries, it will be seen that Holland sent most visitors, Belgium next, then France, Germany, and the United States. The respective proportions of town and country visitors was attempted to be arrived at by comparing the arrivals in London, from April to October, by steam-boats and railways—of course a very rude method, but the nearest approach to the truth. The number of arrivals in London from April to October, 1851 were 4,257,340, against 2,791,733 in 1850, a difference of 1,465,607. But as against this there had to be set off the regular yearly increase in the number of travellers by railway, and other allowances to be made; the inference was drawn that the number of persons who came from the provinces, view the Exhibition slightly exceeded a million: roughly, we may say that the Exhibition was visited by about a million of the inhabitants of London, the same number from the provinces, and about 50,000 foreigners.

The details of the jury awards do not come within our present object; but the following are the general results, as affording materials for comparison.

There were 186 'Council Medals,' 2976 'Prie Medals,' and 829 'Commissions of Honour,' making a total of 5084 honorary distinctions of all kinds. If we take the exhibitors at the estimated number of 10,000, about one-third were deemed worthy of some kind of recognition. Of the total number, 4569 were taken by exhibitors belonging to the United Kingdom, 2819, 197 to foreign countries, including 126 of foreign guests occupied about two-fifths of the space, and

1. It may be interesting to compare these numbers with somewhat cor-
responding details for the 'Crystal Palace of 1851,' as given in the 'Report of the Commissioners for the Exhibition of 1851.'

2. The 'Third Report (1850) of the Commissioners for the Exhibition of 1851.'

3. The 'Palais de la Faire Americaine' of the 1853 World's Exhibition in Paris. The entire number of visitors was 8,560,000; of whom the "Falaise des Beaux Arts" of this number 40,000 were British subjects, and the free admission of women's passports free of charge. The total number of exhibitors was 30,985; of whom the remainder 16,585 were from the United States, and 1,070 from the British colonies.
took off three-fifths of the honours. The greatly-credited 'Council Medals' were awarded in the ratio of 79 to British and 87 to foreign exhibitors; the 'Prime Medals,' 1244 British and 1628 foreign; the 'Honourable Mentions,' 716 British and 1336 foreign.

In relation to different classes of exhibited articles, there were a few striking and instructive facts. In machinery, in manufactures, in metal, and in glass and porcelain manufactures, they considered that the foreigners gained more prizes than all the foreigners combined. In textile fabrics, in fine arts, and in miscellaneous manufactures, the foreign exhibitors took off the honours in the ratio of about three-fifths to two-fifths British. But in the section of raw materials for food and manufactures, the British must be left far behind, with many more coveted prizes, as many prizes as the British (368 to 268). It would be a hasty generalisation to infer from thence that Britain is a manufacturing and not a producing country; but the simple facts of the trade are worthy of note, whether we theorise concerning them or not.

The great honours, the Council Medals, were very unequally distributed as regards the classes of exhibited articles; for out of the whole number of 166, no less than 88 (more than one-half) were awarded for machinery alone. This is a significant fact; showing that the Juries, or rather the Council of Chairmen, were not deterred by the gorgeous display around them from doing justice to the great working agencies by which modern wealth is produced.

We shall confine our remarks to the financial results. The receipts at, and in relation to, the Exhibition, by which it was made a self-supporting concern, were truly remarkable. The admissions were by season tickets, and by payment of one guinea for the unchaging of a ticket, no less than 10,393 gentlemen's tickets at three guineas each, and 6151 ladies' tickets at two guineas each, were sold before the Exhibition commenced, making together 19,507, for more than 52,000L. were paid. About 6000 more tickets were sold during the period of the Exhibition; and it is worthy of note that of these 6000, the ladies took off nearly a thousand more than the gentlemen. The smallest money receipt at the door was on the second day after the opening; the largest was on the third day, the receipts being 1342L. and 1328L., respectively, the former in sovereigns and the latter in shillings. The average of the daily receipts at the doors was 2333L. There were two admission days at 1L., twenty-eight at 5L. thirty at 15L., eighty at 1L., one for season-tickets only, two for exhibitors and their friends, and one for exhibitors and the officials; making up the total, and a hundred and forty-four.

The total receipts amounted in round numbers to 500,000L., that amount being thus made up: subscriptions 67,000L., entrance tickets (i.e. receipts from railway and catalogue contracts, royalty on medals, washing-rooms, &c.) 13,000L. The total expenditure connected with the Exhibition was about 330,000L., leaving a surplus of 176,000L. in the hands of the Committee. The expenses of the exhibition, including interest on Exchequer Bills and additional small receipts was 186,430L. How to apply this large surplus was a most important question. The original announcement to the subscribers was to the effect that, should any surplus remain, it was the intention of the Commissioners "to apply the same to purposes strictly in connection with the ends of the Exhibition, or for the establishment of similar exhibitions for the future." This latter purpose they were however led on more mature reflection to abandon, and they arrived at the conclusion of a temporary, partial, or local character, they could in no way so properly act in the spirit of the pledges held out to the public as by assisting in carrying out a comprehensive scheme which should have for its object "to increase the means of industrial education and extend the influence of science and art upon productive industry;" they having been compelled by their experience, in connection with the Exhibition, to regard as a matter of urgent importance the "systematically planing the public mind in the minds of the classes of the community, to enable them to maintain their pre-eminence in the markets of the world." In their Second Report (1852) the Commissioners review the existing means and deficiencies of the country in respect of technical and mechanical, and the means supplied to supply the deficiencies which they have pointed out. Properly to carry into execution any comprehensive scheme would require the liberal co-operation of the public and the government. The sum in the hands of the Commissioners would go but a small way towards meeting the requirements of the case. It would suffice however to prepare the ground, and they determined so to employ it, leaving it to the public to complete the work when its importance should have become fully understood and appreciated. The "The Commissioners feel it their duty to deal with the funds in their hands in such a manner as may ensure the greatest amount of advantage being derived from the modes of their application; and that the public and its friends should be left in no manner could this be effected so well as by carefully preparing the basis and framework of a large and comprehensive plan, and securing facilities for its execution, leaving it to the various interests concerned to give substance to it, whilst the perfect development of the system must be left to the public as a whole, in union with the wants at present manifested, and extending it as those wants become greater and find expression on the part of the public. In investigating the causes which have led to the decay of English and of larger institutions of the character alluded to, and the reasons why the great amount of private exertion and of State endowment already mentioned has not operated with all the advantage that might have been looked for, we have found two, which have more especially attracted our notice: the first being the want of that harmony of system which would admit of an economic and combined action of the forces already in existence towards a common end; and the second, the want of actual space for their development in this overcrowded metropolis." And having pointed out the general lines of the scheme which appears to them that, "The two things to be aimed at are the adoption of a system and the securing of a locality where that system may be developed. We feel that we are best engaged in assisting in the first stage of the matter, in submitting for consideration and discussion on the part of the public such a system, by ourselves providing such a locality, bearing in mind that the filling up of the plan that may be adopted must be left to the wants expressed, to the public at large. The great object of our efforts should be the methods of the institutions, societies, and individuals, aided by the efforts of the Government to develop more fully the institutions already founded by it, and which are so much appreciated by the public."

Acting on the suggestions of this report, the Government in the speech from the Throne at the opening of the session of 1852-53 invited the "aid and co-operation of parliament in promoting a comprehensive scheme" for the advancement of the Fine Arts and of Practical Science, which they considered in effect the scheme of the Commissioners. After some discussion the House of Commons voted the sum of 150,000L. towards the purchase of a site on which a National Gallery and Museum might be erected, and which should be available for the purchase, the income of the site being provided by the Commissioners out of the surplus remaining at their disposal. The land purchased by the Commissioners consisted of the well-known Gore House estate of 21 acres, and the adjacent site of 2 acres, and of the Villars estate of 48 acres, and some other adjacent land, which "were deemed indispensable for the completeness and development of the capacities of the property." Altogether it formed a compact estate of about 56 acres, its extreme length being half a mile, its average width a quarter of a mile. The Commissioners were anxious to secure other adjoining property to the extent of about 80 acres then obtainable, making in all about 170 acres, but the Government demurred, and the opportunity was lost, it being feared that the building would be in the way of the completion of the purchases the government subsequently obtained an additional vote of 27,000L; and the Commissioners, having obtained the necessary powers from parliament, have formed upon the estates lines of road, sewers. The total expenditure upon the Kensington estate up to Jan. 31, 1858, has been 312,036L., and 54,716L. remains to be paid in completion of one of the purchases. The Commissioners wish to retain in their hands a balance of 20,000L., which they consider they may safely retain for the purpose of meeting current expenses and providing for contingencies. The Commission itself has been incorporated as a permanent body, and certain members of the Government have officiated as its officers.

The "comprehensive scheme" of the Commissioners proposed eventually to bring together, upon the locality they have purchased, all the existing metropolitan institutions, whether dependent on government or on private support, which have in view the advancement of science and art in
their various branches, and to "establish a central point of union for those who in so many ways devote their energies to the same ends, especially in respect of the practical application of science and art to productive industry." They thus, in connection with the enlarged system of industrial instruction of which they urged the necessity, hoped that instead of being behind most other European nations we might take the lead in Industrial science and art, as well as in mechanical engineering industry and enterprize. But the Commissioners have been doomed to see their scheme, like so many another castle in cloudland, reduced to much humbler dimensions than that in which it at first presented itself to the spectators. As a first step it was proposed to remove the National Gallery, and a noble site with a frontage of a thousand feet (the depth being practically unlimited) nearly facing the site of the Exhibition of 1851, was proffered by the Commissioners. A Committee of the House of Commons in 1853 reported unanimously in its favor, and the Government appeared to be inclined to support the proposition, but the Commissioners appointed to consider the subject in 1857 decided by a majority of three votes to one against removing the national collection from Trafalgar Square; and in consequence of their report a survey has been made of the ground in the rear, and estimates given of the cost of enlarging the present building, or erecting a new one on its site. So with reference to the Art-Collections in the British Museum, the feeling of the Trustees has been decidedly expressed against any removal. So again, a new building has been erected for the collection of vegetable products at Kew, which were proposed to be taken to Kensington. Then the Learned Societies were averse to migrating so far westward, and provision has been made for their accommodation at the Westminster House, Piccadilly, which was purchased by the Government.

But a very definite advance has been made. By manufacturers and artizans, and by the general public, as well as by the Commission, the great importance of systematic art instruction is now generally admitted. A new department of the Government has been created, whose special duty is the promotion of Industrial Art and Science; and to which was intrusted the direction of all previously existing government scientific and art institutions, and the encouragement of all local institutions of a similar order. [Sciences and Art, Department of, S. 2.] Upon the estate purchased by the Commissioners a great practical step towards the realisation of a main feature of their scheme has been taken. In a building which has been adapted to the purpose, instruction in the mechanical arts is given to young boys. The highest standing is regularly given, and an excellent library has been formed for the use of the students; more strictly scientific courses of lectures are at the same time delivered at the Metropolitan Asylum of Science, in Jermyn Street—the two institutions making together a school nearly resembling that desired by the Commissioners. In a spacious temporary iron building at the south-eastern angle of the estate have been brought together for public exhibition, industrial, educational, and art collections, which, though as yet necessarily very incomplete, and in some cases only rudimentary, are all of great value and interest; and having been arranged and shown so as to suit the convenience of the industrial classes, they have proved remarkably attractive. These collections include a Museum of Patent Inventions, A Trade Museum, a Museum of Ancient and Modern Manufacturers, a Museum of Animal Products, a Museum of Domestic Economy, the Architectural Museum forming part of the Great Exhibition, and paintings by British artists presented to the nation by Mr. Sheepehans, and collections of British sculptures, drawings, etchings, &c. At the present moment [March 1858], a collection of models and drawings submitted in competition for the Memorial to the deceased Commissioners is in some measure the Great Exhibition is also being exhibited in the 'South Kensington Museum,' but the true memorial of the Exhibition of 1851 will be the Exhibition Estate, with the Museum of Art and Industrial Science collected upon it.

EYEBRIGHT. [Euphrasia.]

F

FABER, REV. GEORGE STANLEY, was born on the 25th of October 1773. He was the eldest son of the Rev. Thomas Faber, who was descended from a French refuge who came over to England after the revolution of the edict of Nantes. He was educated at the grammar-school of Hippleholme, near Halifax in Yorkshire, where he remained till 1799, when he entered at University College, Oxford. He took his degree of B.A. in 1792, and before he had reached his twelfth year, was elected a Fellow and Tutor of Lincoln College. He took his degree of B.A. in 1795, served the office of Proctor in 1801, and in the same year, as Bampton Lecturer, preached the discourses which he shortly afterwards published under the title of 'Horse Mosaics.' He took the degree of B.D. in 1803, and married in the same year. Having by this step relinquished his fellowship, he went to reside with his father at Calverley, near Bradford in Yorkshire, where for two years he acted as curate. In 1805 he was collated to the vicarage of Stockton-upon-Tree, in the county of Durham, which he resigned in 1811; and in 1812 he was collated to the vicarage of Long-Newton, where he remained till 1831, when Bishop Burgess presented him to a prebend in the cathedral of Salisbury. In 1832 Bishop Van Mildert gave him the mastership of Sheberburn Hospital, near the city of Durham, which he was to hold when he came to Long-Newton. During his mastership he considerably increased the value of the estates of the Hospital. He rebuilt the chapel, the house, and the offices, and greatly improved the grounds; he augmented the incomes of the incumbents of livings under his patronage, restored the chapels of his churches, and erected agricultural buildings on the farms. He died at his residence, Sheberburn Hospital, on the 27th of January, 1854.

The theological writings of Mr. Faber, particularly those on prophecy, have had a very wide circulation. One of the principles for the interpretation of prophecy which he chiefly employed to establish and exemplify was, that the delineations of events in prophecy are not applicable to the destinies of individuals, but to those of governments and nations. His writings are numerous, and we can only mention a few of the most important—Horse Mosaics, or a View of the Mosaical Horse—The Christian Prophecy, or a view of the Profane Antiquity, their internal credibility, and their connexion with Christianity, 2 vols. 8vo, 1801; A Dissertation on the Mysteries of the Cabiri, or the great gods of Phoenicia, Samothrace, Egypt, Troas, Greece, Italy, and Greece; 2 vols. 8vo, 1808; Dissertation on the Prophecies which has been fulfilled, are now fulfilling, or will hereafter be fulfilled, relative to the great Period of 1380 Years, 2 vols. 8vo, 1808; A General and Connected View of the Prophecies relating to the Conversion, Restoration, Union, and future Glory of Judah and Israel, 3 vols. 8vo, 1809; The Origin of pagan Idolatry, 3 vols. 8vo, 1816; A Treatise on the Genius and Object of the Patriarchal, the Levitical, and the Christian Revelation, 2 vols. 8vo, 1852; The Sacred Cause of Prophecy, or a Dissertation on the Prophecies which are to be the Grand Period of Seven Times, 3 vols. 8vo, 1858; Eight Disquisitions on certain connected Prophetic Passages of Holy Scriptures bearing more or less upon the Prophecies of the Messiah, 4 vols. 8vo, 1845.

FAIRFORD. [Glos.]

FALKINGHAM. [Lincolnshire.]

FAREWELL. [Hampshire.]

FARY, JOHN, civil engineer and draughtsman, was born at London on March 9th, 1791, and educated at Woburn, where his father was agent to the Duke of Bedford, who took much interest in the progress of agriculture. John Fary, senior, was frequently employed in making reports on geological questions; wrote a 'General View of the Agriculture, Cattle and Minerals of Derbyshire,' 4to (3 vols. 8vo, Lon-
well in the progress of his pupils as in their number and social position. His success as a teacher of course did much to spread the light of his discoveries and to increase the merits of his works effectively maintained. His course was one of steady prosperity, quite devoid of adventure. His time was constantly occupied either in teaching or painting, and he could only afford to reserve a little time to paint with the materials for new pictures. For many years Mr. Fielding held the office of President of the Society of Painters in Water-Colours, and his position was generally recognised as that of the head and representative of this branch of art; the more so, as he had done one little in consequence of the estimation in which his personal as well as professional qualities were universally held. He died March 3, 1856, in his sixty-eighth year, at Worthing, Sussex, where, or at Brighton, he had for a long period been accus-

Figtés. [Gallicole.] FĪLICES, or Filicae. A natural order of Plants, being the highest group of the class Cryptogamae, or Acro-
gena. The species are flowerless plants, consisting of leafy
fronds, which are produced from a rhizome unfolding in a
spiral manner, and traversed by veins which form definite parts
on the surface, and produce unilocular, rarely
multilocular, cases containing reproductive spores.

The branchlets which bear the spores get little attention in
their study, and on modifications of which modern classifi-
cations depend, are the veins and organs of reproduction.
The veins are either simple or divided by a midrib, and from the
branch of development, or from one side of an eccentric or unilateral cost. The or-

The second kind of organ, the so-called ‘ovules,’ are
fewer in number and present different characters in different
stages. At first they appear as little round cavities in the
cellular tissue of the pro-embryo, lying near its centre, and
opening on the under side. In the bottom of the cavity is
seen a little globular cell, the so-called ‘embryo-sac.’ It is stated
by Count Suminski, that while the ovule is in this state one
or more of the spiral filaments make their way into the cavity,
coming in contact with the central globular cell. The four
cells bounding the mouth of the orifice grow out from the
general surface into a blunt cone-like process, formed of four
parts, which are arranged in an arcuate line, placed one
intercellularly standing down to the cavity below. These
cells become divided by cross septa, and grow out until
the so-called ovule exhibits internally a cylindrical form
composed of four tiers of cells, the uppermost of which
gradually converge and close up the orifice of the four
leaving down between them. Meanwhile the vesicular head
of one of the spiral filaments has penetrated into the globular
cells of the embryo-sac, enlarged in size and undergone
multiplication, and in the course of time displays itself as the
embryo, producing the first frond and the terminal bud,
whence the regular fern-stem is developed. In considering
the importance of these phenomena, the author assumes the
analogy here to be with the process of fertilisation in flowering
plants. The pro-embryo is a structure formed of the upper
part of the embryo from the vegetal head of the spermatossora
from the end of the pollen tube into which it has penetrated
into the embryo-sac.

The transmission of these statements naturally attracted
great attention, and since they appeared we have received
several contributions to the history of these remarkable
structures, some confirmatory, to a certain degree, of Sumi-

"In the early part of 1849, Dr. Wigand published a series
of researches on this subject, in which he subjected the
assertions of Suminski to a strict practical criticism; the
conclusions he arrived at were altogether opposed to the
author’s. He says that all the filaments which are seen in the
organs, and he never observed the entrance of the spiral fil-
ments into the cavity of the so-called ovule. About the

argued that the existence of these cellular organs, producing
spiral filaments, the so-called spermatossoras, upon the ger-
mination of the spores, and their development into any way connected with the reproductive processes.

"But an essay published by the Count Suminski in 1848
totally changed the face of the question, and opened a wide
field for speculations on the subject, just as it was beginning to fall into disfavour. Count Suminski’s paper gives a minute history of the course of development of the Ferns, from the germination of the spore to the produc-
tion of the regular fronds; and he found this development to exist in the following manner. The cellular

The cellular organs seen by Nāgeli were shown to be of two
perfectly distinct kinds, and moreover to present characters
which gave great plausibility to the hypothesis that they
represented reproductive organs; moreover, this author ex-
pressed the conviction that they had obtained a decided
value by observing an actual process of fertilisation to take place
in the so-called ovules, through the agency of the spiral
filaments or spermatossoras. The main points of his paper
may be briefly summed up as follows.—The fern-spores first
produce a filaments process, in the end of which cell-
development goes on until it is converted into a Marchantia-
like frond of small size and exceedingly delicate texture, pos-
sewing hair-like radicles threads on its under side. On this
under side is seen the so-called antheridia, which contain
cellular organs of two distinct kinds. The first, which he
terms antheridia, are the more numerous, and consist of some
what globular cells seated on and arising from single cells of
the cellular Marchantia-like frond. The ground of the
deciduous antheridia, contains millions of small spermatossora, in each of which is developed a spiral frond, coiled up in
the interior. At a certain epoch the globular cell bursts, and dis-
charges the vasicles, and the spiral framents moving within
the vessels, at length make their way out of the fronds and
swim about in the water, displaying a spiral or helical form,
and consisting of a delicate filament with a thickened clavate
extremity; this, the so-called head, being said by Count
Suminski to be a hollow vessel, and to be furnished with six
spiral filaments or spermatossoras. The locomotion of these cells, in each of which is developed a spiral frond, is

FIL

DIGITIZED BY GOOGLE
same time M. Thuillier published a series of observations on the Flora of Ferns. In these he merely confirmed and corrected the statements of Suminski, respecting the antheridia, and did not notice the so-called ovules.

Towards the close of the same year Hofmeister confirmed part of Suminski's statements, and opposed others. He stated that he had observed distinctly the production of the young plant (or rather the terminal bud for the new axis) in the interior of the so-called ovule; but believed the supposed origin of it from the end of the spiral filament to be a delusion. He regards the globular cell at the base of the canal of the ovule as the germ, or embryonal vesicle (the embryo originating from a free cell produced in this), analogous to that produced in the pistillidia of the Mosses. He also describes the development of the ovule differently, saying that the canal and orifice are opened only at a late period, the separation of the conjuntive walls of the four rows of cells.

About the same time appeared an elaborate paper on the same subject by Dr. Hermann Schacht, whose results were almost identical. He found the young terminal bud to be developed in the cavity of one of the so-called ovules, which were developed exactly in the same way as the pistillidia of the Mosses. He stated also that the cavity of the ovule is not open at first, and he declares against the probability of the ovule being filled with the products of the filaments. He observed this, much less a conversion of one into an embryo. In the essay of Dr. Mettenius, already referred to, an account of the development of the so-called ovules is given. His observations did not decide whether the canal of the ovule, which begins to be formed with the first filament, appears only subsequently, when it is entirely closed above. Some important points occur in reference to the contents of the canal. The contents of the canal in a mature condition consist of a transparent mass of homogeneous matter, containing the filaments, granules, and here and there large corpuscles, are embedded. It reaches down to the globular cell, or embryonal sac, and is in contact with it. This mass either fills the canal or diminishes in diameter from the blind end of the canal down to the embryonal sac. In other cases it possesses the form represented by Suminski, having a clavate enlargement at the blind end of the canal, and passing into a twisted filament below; in this latter shape it may frequently be pressed out of the isolated ovule under the microscope, and then a thin transparent membrane-like layer is seen, sometimes observed on its surface. In other cases the contents consisted of nucleated vesicles, which emerged separately or connected together.

The embryonal sac contains a globular cell, or embryonal vesicle, in the canal, the development of the embryonal sac constituting the division of this into two, which go on dividing to produce the cellular structure of the first frond.

With regard to the contents of the canal the author says, 'Although the filaments are first observed as separate, regard to the origin of the contents of the canal of the ovule, yet my observations on the development of the ovule do not allow me to consider them, with Suminski, as spiral filaments in course of solution; just as little have I been able to convince myself of the existence of the process of impregnation described by that author. It rather appears to me that the possibility of the entrance of the spiral filaments and the impregnation cannot exist until the tearing open of the blind end of the canal in the perfectly-formed ovule, as after the opening of the so-called canal of the style in the pistillidia of the Mosses.

Another contribution has been furnished by Dr. Mercklin, the original of which I have not seen, but depend on analyses of it published in the 'Botanische Zeitung,' and the 'Flora' for 1851, and further in a letter from Dr. Mercklin to M. Schacht, which appeared in the 'Linnaea' at the close of last year.

He differs in a few subordinate particulars from M. Schacht, in reference to the development and structure of the prothallium, or pro-embryo, and of the antheridia and spiral filaments; but these do not require especial mention, except in reference to the vesicular end of the spiral filament, which he regards as the remnant of the parent vesicle, from which the filament had not become quite free. The observations referring to the so-called ovule, and the supposed process of impregnation, are interesting in their theoretical bearing on the problem of development.

1. The spiral filaments swarm round the ovule in numbers, frequently returning to one and the same organ.

2. They can penetrate into ovules. This was seen only three times, but over a course of a whole year, and under different circumstances; twice in spiral filaments, which, not seen to enter a still widely open young ovule, then come to a state of rest, and after some time assume the appearance of a shapeless mass of mucilage; the third case of penetration occurred in small deeply opened ovules, and was seen to enter these filaments, like the spiral filaments, acquiring a brown colour with iodine. These mucilaginous bodies sometimes exhibit a twisted aspect, an opaque nucleus, or a membranous layer, peculiarities which seem to indicate existence of an organisation.

3. In the tabular portion of the ovule, almost in every case, peculiar club-shaped granular mucilaginous filaments occur at a certain distance from these filaments, like the spiral filaments, acquiring a brown colour with iodine. These mucilaginous bodies sometimes exhibit a twisted aspect, and the opaque nucleus, or a membranous layer, peculiarities which seem to indicate existence of an organisation.

4. The club-shaped filaments are seen seated at the lower capitate extremity, and have been found in contact with the embryonal sac, or globular cell, which forms the rudiment of the future frond.

5. The spiral filaments, which cease to move and fall upon the prothallium, are metamorphosed, become granular, and swell up.

Hence the author deduces the following conclusions:

That these club filiform masses in the interior of the ovule are filiform masses, like the spiral filaments, which, not seen to enter a still widely open young ovule, then come to a state of rest, and after some time assume the appearance of a shapeless mass of mucilage; the third case of penetration occurred in small deeply opened ovules, and was seen to enter these filaments, like the spiral filaments, acquiring a brown colour with iodine. These mucilaginous bodies sometimes exhibit a twisted aspect, and the opaque nucleus, or a membranous layer, peculiarities which seem to indicate existence of an organisation.

An important point in this essay is the view the author takes of the whole process of development in this case. He regards it as not analogous to the impregnation in the Phanerogamia, since the essential fact is merely the development of a frond from one cell of the prothallium, which he considers to be merely one of the changes of the individual plants. In the case of this fern the author is on the subject, with the exception of Wigand, the first frond, with its bud and root, an Embryo, and regard it as a new individual; or at all events, even a distinct member of a series of forms, constituting collectively the representative of the species.

Finally, Hofmeister, in his notice of this essay in the Flora, declares that the development of the so-called embryo, or first frond, commences not by the subdivision of the globular cell, or embryonal sac, but by the development of the embryonal sac in the division of this into two, which go on dividing to produce the cellular structure of the first frond.

The position of the Ferns in a natural system of classification has not been a matter of much difference. Their imperfect organs of reproduction have at once led to their being placed by most botanists among Cryptogamia; nevertheless Bory St.-Vincent elevates Ferns to the rank of a class intermediate between Monocotyledons and Acotyledons, or Cryptogamia; at the same time he rejects the view of Jussieu, who, from the mode of germination of their spores, placed the Ferns among the Monocotyledons. Their relation with the flowering-plants is seen through Cycadaceae, with which order they agree in their gyrate vernation and their pinnate leaves. Their affinity with Cryptogamia plants is obvious in the Equisetaceae and Lycopodiaceae. The order of the Ferns may be divided into the following sub-orders, which Landly regards as the rank and value of orders:

I. GLEICHENIACEAE. The thymus with a transverse or obliquely transverse complete elastic anulus or ring, bursting vertically. The thymus is non-nitrophic only in the Southern Hemisphere, of a harsh and rigid texture, simple or generally with copious dichotomous branches and gemmae in the axils; the ultimate branches pinnaed. None of the genera of this order, as understood by Hooker, are British. The species are about forty species, distributed generally incomplete ring, bursting transversely and irregularly.

II. POLYPodiaceae, with the sori dorsal, often near or at the margin, various in form, sometimes constituting an uniform linear or spreading mass, naked or furnished with an involucrum, or the sori grouped together; the veins of the leaflets are generally fine. They are extensively distributed, being natives of the American Continent, southern Europe, and parts of Asia. The species number about six hundred.
inhabit almost every part of the world, from the tropics to the arctic and antarctic regions; they are exceedingly variable in size and appearance, including the largest tree-ferns and the smallest herbaceous species. It contains by far the largest number of genera of any of the sub-orders. Of these, some are extensive, and have no British representatives, as Cyathae, Hemidactyl, Allophila, Dicksonia, &c.

III. Osmundaceae has the thecæ with an operculiform ring, or without one, reticulated, striated with rays at the apex, bearing long-hairs, and usually externally. The species of this sub-order are not numerous.

IV. Danacæae. The thecæ sessile, without any ring, concrete into multilocular sub-immersed masses, opening at the apex. This is also a small sub-order, with three genera — Dermagic, Kellwingia, and Ceratopteris.

V. Ophioglossacæae. The thecæ single, roundish, coriaceous, opaque, without ring or cellular reticulation, half 2-valved, with a straight vernation. It embraces the genera Ophioglossum, Selaginella, and Botrychium.

The following is an arrangement of the British genera of Fungi —

Sub-Order Polyposidae.
Tribe Polyposidæ. The sori nearly circular, without an indusium.
Genera. Allosorus, Polyposidium, Woodia.
Tribe Aspidiæa. The sori nearly circular, covered by an indusium.
Genera. Allosorus, Polyposidium, Woodia.
Tribe Aspleniææ, Polyplacotheca, Cytopteris.
Tribe Asplenidæae. The sori oblunget or linear, covered by an indusium opening longitudinally on one side.
Genera. Althrym, Asplenum, Selaginella.
Tribe Aspleniææ. The sori elongate, without an indusium.
Genus. Asplenium, Tectaria.
Tribe Adiantariae. The theciæ covered by a marginal or sub-marginal elongated part of the frond, or by a separated portion of the cuticle, resembling an indusium.
Genera. Blechnum, Pteris, Adiantum.
Tribe Hymenophyllæae. The theciæ opening irregularly; the ring oblique, eccentric, transverse, complete; the receptacle terminating a vein at the margin of the frond.
Genera. Trichomanes, Hymenophyllum.
Sub-Order Osmundaceæae.
Tribe Osmundææ. The vernation circinate; the rachis solid; the thecæ stalked.
Genus. Osmunda.
Sub-Order Ophioglossaceæae.
Genera. Ophioglossum, Botrychium.
The Ferns have a wide geographical distribution, the herbaceous and shrubby kinds being found towards the north and south poles, whilst the tree-ferns rival the gigantic palms in the forests of tropical climates. It is these last which give a peculiar character to the vegetation of the country where they grow, as their foliage and stems differ altogether from any that are observed among the flowering plants. The proportion which they bear to other plants varies much in different parts of the world. In Jamaica they are in the proportion of 1 to 9; in New Guinea as 25 to 125; in New Ireland as 13 to 60; in the Sandwich Islands as 42 to 160; on continents they are less numerous; in equatorial America 1 to 36; in Australia 1 to 37; in France 1 to 63; in Portugal 1 to 116; in the Greek Archipelago 1 to 297; in Egypt 1 to 971. In the north their proportions are greater. In India and the Sandwich Islands 1 to 31; in Sweden 1 to 35; in Iceland 1 to 18; in Greenland 1 to 10; and the North Cape 1 to 7.

The properties and uses of the Ferns are not in proportion to their numbers in the vegetable kingdom. Many of them deposit starch in their rhizomata, from which food may be prepared. The roots of Nephrodium excentrum are eaten in Nepal; those of Angiopteris evecta are used in the same manner in the Sandwich Islands. Diplazium excentrum, Cyathea medullata, Petasus excentra, and Gleichenia dichoto-
toma, all yield starch, and are employed as food in different countries. The Adiantum Capillia Veneris yields astringent and aromatic secretions. Some of the American polypondiums are said to possess medicinal effects, and are used as anti-rheumatic, anti-venerial, and febrifugal remedies. The Angiopteris evecta yields an aromatic oil, which is used in the Sandwich Islands to perfume the fixed oils, as coca-

The stem in many species contain bitter principles, and have hence been used as tonics. Species of Aspidium and Asplenium have been used in European medicine. The Brazilian negroes form tubes for their pipes from the stems of Mertensia dichotoma. Osmunda regalis had at one time a great use in the manufacture of hats. FILLANS, JAMES, sculptor, was born at Wiltoncourt, Lanarkshire, on the 27th of March, 1808. His father having become reduced in circumstances, removed into Renfrewshire while James was yet a child, and the boy was early set to the drudgery of cartage. In time of this, he became apprenticed to a weaver at Paisley; but disliking the occupation, was at the end of a year placed with a stone-

At this business, after having served his appre-

He, during his spare hours, even when engaged as a weaver, been teaching himself to draw and to make clay models, and by perseverance he attained sufficient skill to win some local celebrity. Motherwell, the poet, was at this time the editor of the 'Paisley Advertiser,' and he warmly encouraged the young man's tastes, and judiciously guided his aspirations. Fillans found in Paisley, at his moderate prices, patrons for small portraits, busts, and fancy figures; but he determined to go to Edinburgh and Glasgow for the great. In order to avail himself of the additional facilities that city afforded for improvement in art, as in the expectation of increased patronage. He however met with both, and after a time was in a condition to visit Paris for a further study. On his return in 1836 he established himself in London, where he found many warm Scotch friends, among others Allan Cunningham, who sat to him for his bust, and introduced him to Chantrey.

At the exhibition of the Royal Academy in 1837, Fillans had seven busts, including one of Allan Cunningham, which attracted some attention. He now produced a Tam o' Shanter jug; 'The Birth of Burns,' an alto-relievo, and other designs of a similar kind, forming a Burns' series, which have been much submitted and praised; and he received a commission for a bust of Mr. Oswald of Auchinure, for his tenantry, which led him to visit Italy. Mr. Oswald being then resident on the continent. While still depending upon portrait busts for his means of support, Mr. Fillans was not neglectful of other subjects. His chief work of this order was a life-sized group in marble, 'The Blind teaching the Blind,' a work of real merit and some originality: it was exhibited in Glasgow, where it produced a great sensation. His 'Boy and Fawn' was also produced about this period. He established his fame were his colossal statue of Sir James Shaw, for the baronet's native town of Kilmarnock, and the bust of John Wilson—both characteristic works, that of Wilson being indeed by far the most striking. His most successful portraits were received with enthusiasm, and the sculptor was congratulated with two or three public dinners given in his honour. Still, though so far successful, he found his income insufficient to maintain establishments in London and Glasgow, and he res-

To Queen victoria the commissions having being chiefly derived from his countrymen. He returned to Glas-
gow in 1851, but his health, already impaired, became gradually worse; and at length an attack of rheumatism overpowered him. While at the Clyde in 1854, he was attached to Mr. Reid in Glasgow, but which would have been as well left in the manuscript, except as evidence of the sculptor's kindheartedness. Fillans used the pencil as well as the chisel, but with by no means equal success. He was apprenticed to Mr. Miton, an engraver of shop-bills, coats of arms, &c., but by devoting his leisure to the study

FRANCE [APPEAL AND TAXATION, S.2.]
FINDEN, WILLIAM, line engraver, was born in 1757. He was apprenticed to Mr. Miton, an engraver of shop-bills, coats of arms, &c., but by devoting his leisure to the study
of the works of James Heath, and others, he acquired, by his own industry and intelligence, so much facility in the use of the burin, and displayed so cultivated a taste, that after he began to work on his own account he soon found ample employment in engraving books and plates. Among his first successes in this line, his engravings of Smirke's illustrations of 'Don Quixote' have been singled out for special commendation. Being very industrious, and always remarkable for a certain sedateness in his manner of adopting the most pesky and prolix occupations of his day, and in course of time to be one of the most popular engravers of the day; and he was selected to engrave 'the royal portrait' by Lawrence, of George IV. seated on the sofa. It was a plate of large size, and for engraving it Mr. Finden received the sum of £50. It was a very difficult, to remove the nature of the fundamental organ from which they had been produced. This latter has been termed Retrogeneric Metamorphosis. As examples of it, we may mention the different monstrosities, the doubling of a flower through the transition of the stamens into petals, the transition of the petals and sepals into the common leaves of the plant, &c. This mode of establishing the foundations of the doctrine of metamorphosis has however two essential faults: since, in the first place, it seeks to obtain individual facts by means of hypotheses and comparisons; while, secondly, its progress depends entirely upon favourable circumstances. The only correct and sure ground on which to rest this doctrine is the history of development.

In Phanerogamic Flowers the following parts are distinguished: the sepals, which are termed the Calyx (Phylla); the petals, which are termed the Sepals; the filaments, which are termed the Stigmas; the anther, which is termed the Filament (Filamentum).

The flower of Phanerogamic is the only physiologically determinate organ of the plant, since it contains the apparatus for the regular propagation. But to this only two parts contribute—namely, the stamens, as generators and the ovules, as the receptacles of the seed—while the stamens and the ovules, which are termed Carpels or Carpilla, are in the stamens the lower thread-like portion, which is termed the Filament (Filamentum), is distinguished from the upper thick and hollow part, containing the Dust (Pollen), called the Anther (Anthera). In the pistil, the lower part surrounding the Ovules or Seed-Buds (Spermillum) is called the Germen; the upper free part, which is usually covered with papillae, is termed the Stigma, and between these two frequently a stalk-like elongation of the germen occurs, called the Style.

b. The Spermophore.

b. The Seed-Boards.

The Ants have been called the male organs of a plant (with the superfluous collective term Androecium); the Seed-Boards and their receptacle the Pistil, the female parts (together the Gynoecium). A flower that contains both parts is termed Hermaphrodite (the Binandric, bithecous). Flowers that contain on one or more of those kinds of organs are termed Unisexual Flowers (Flores Unisexualis, Diclini). When, in the last case, male and female flowers (mas et femina) appear on the same individual plant, such plant is termed Monoeious (the Plurianthemid, Sonchus, Diclini). When individuals the plant is termed Dichores (Planta Dioica).

An Inflorescence which contains both male and female flowers, also is termed Inflorescentia Androgynea. Here again it must be distinguished whether the male and female blossoms appear on the same or on separate (or sometimes, more commonly) different parts of the same plant (Dichlina); or whether, through the suppression of one or other part, a pseudo-dichotomous condition appears in a flower formed on the plan of a hermaphrodite. This latter condition, which is never found to exist, though all the examples of any species of plant, brings monocious and distinct species into hermaphrodite genera, and suggested to Linneaus the establishment of his 32nd class, Polygynia, where in one and the same species male, female, and hermaphrodite flowers are present.

There are very few flowers of so simple a structure that they consist only of one simple essential part, so that no formation of androecium is possible within the flower; and the extremity of the pedicel immediately supports the floral parts. An example of this case in Euphorbiaceae, Euphorbia, where the end of a pedicel bears one single stamen; also in the male flower of the Abietinae, where one single foliar organ, converted into a stamen, constitutes the entire flower. It is also the case in certain male flowers of Tussa, where the small pedicle, clothed with bracts, terminates immediately in the naked seed-bud. In the generality of flowers however several parts are united which do not stand at equal heights on the axis, and thus more or fewer unions may take place either between the parts and the axis (Antherophyta), or between the parts in the flower or between the stamens and the gynoecium (Gynomorph). The latter is generally termed German Stipitatum. There are examples of both in the Passifloraceae and the Capparidaceae.

A considerably longer part, without elongation of the individual stamens, frequently occurs as a gynophore in flowers which contain many gynoecia (as in the Rosaceae, the Ranunculaceae, Magnolliaceae, &c.). Again the gynophore is often presented as a hemispherical or cushion-like part, as in some other Rosaceae and Ranunculaceae. A very rare form of it is that of a reversed cone, which bears the gynoecium upon a base turned upward, as in Neotibium. In the rarest instances, with the exception of this case, the axis of the flower is elongated within the floral parts even without ending as a gynoecium; but this does sometimes occur, as in the male flowers of some Palms and other plants; for example Chamaedorea, where the points of the petals unite with the apex of the axis of the flower which passes up through them. In many other cases, within the division of the corolla, the corolla develops obliquely, and rises up on one side, especially beneath the gynoecium, so as to appear as a part of its side-wall; this happens most with the Grasseae. A similar circumstance, arising from a similar cause, happens when many single gynoecia are present in one flower, by the division of the torus, which forms the basis of each of those gynoecia, and thus assumes the appearance of forming a part of the whole gynoecium (as in Psamomogen and Dryasaceae).

But the stamens in the Disc, or in a hollow cup, is far more frequent in the flower. If the collective indecides of the flower form a hollow body, or even a cylindrical elongated tube, which incloses only seed-buds, and has upon it all the floral parts upon its upper end, all this is the so-called Inferior Germen or Ovary (German Inferen).
a single foliar organ grows together by its edges into a tubular or cup-like organ, as, for example, occurs frequently in the so-called monomorphic floral envelope (Bracteole); or that several foliar organs grow together by their edges: this commonly affects all the edges of the floral leaves, but sometimes two or three leaves are united, as with the calyx of Gentiana lutea. So, again, this process is usually simultaneous in development at all the edges of a circle; but it sometimes happens very much later—a, on two uppermost leaves of Nicotiana, the lateral edges of the calix and corolla of Triticum and the floral ligulata of the Compositae; or b, with each pair of leaf-edges at the side of the leaf-circle, whereby the two- or the four-edged (partes bilabiate) of descriptive botany arise. Another kind of blending also occurs in the calyx leaves but in which the young monads only and only one in the bracts and bracteoles, namely, the cupula of the Calyptrum; this is, the blending together of two more circles, as in the two circles of the floral envelopes of melaleuca, or in these and the two circles, stamens, in the circle of petals and stamens, in the Lobelia, &c.; and in general in all flowers to which are ascribed stamens perianthio vel corolla (not calyx) inseri.

The coherence of the stamens of one or more circles has become more perfect during the progress of the flower, and, according to the number of brotherhoods in a flower, Monadelphia, Diadelphia, Polyadelphia. When the foliar organs of the flower are coherent, the blended part is termed the Tube (Tubus Perianthii, Calycis, Corollae, &c.); the free part is termed the Throat (Ovarii, Throat of the Flower) (Tubus). One of the most striking examples of coherence, which also has no analogue in the stem-leaves, is found in the blending of the foliar organs of the flower at the point only, the union never extending farther; so that the foliar organs of Chamaedorea, Cassavina, and in the androphore of Symphymena montanum (1).

Abortion in the flower means that some part present in the receptacle, whether the flower is perfect in the growing condition, or if it becomes disengaged from the perianth and gradually perfecting of the flower, and thus at last retires from observation. There is no other kind of abortion. So soon as the individual parts of a flower become distinct members, the foliar organs appear arranged around an ideal and real axis of the flower (the axis, organs of the flower), and in the redimentary condition always regular. Through subsequent unequal development of the single parts, the flower frequently becomes unsymmetrically, or, as it is called, irregular. This irregularity is always such that the upper part of a flower becomes larger and better developed than the same part of the under part; very rarely the cloud of flowers, or of leaves, is such that the upper part of a flower is smaller than the same part of the lower part so that the flower is asymmetrical. In the case of the axis, organs of the flower, the accident of some parts, especially the calyx, remaining even regular even in unsymmetrical flowers; yet there are cases in which this is the only symmetrical part, as in the calyx of the garden plant, or of the corolla of Exanthes spiralis. If the unsymmetrical flower, with or without coherence of its parts, is divided into two halves, an upper and under, developed in different ways, they are generally termed bilabiata; but if only one single foliar organ is developed in an aberrant form, that leaf acquires the name of Labellum, or Lip. Rare indeed are the cases where the entire flower is unsymmetrical, as in Goodyera discolor.

It is not possible to state in general terms the number of parts which may unite to form a flower. We find of foliar organs alone sometimes as few as six or eight united in one flower. Certain combinations, on the contrary, are rarely met with: no monomorphic flower possesses double floral envelopes. When the various parts of the flower are present in the same number as the petals, and if the flower remains undivided, in two circles (Whorls) at the same height on the axis, and at the same time. When circles containing members of equal number follow in succession, the members of the one circle usually stand opposite the interspaces between the members of the preceding circle (the circles and their members being thus they seldom stand precisely before them (the circles and their members opposite). But it by no means is to be assumed that the members of each circle are always of equal number in a flower. The number of members increases as the flower advances, that is, as the flower ages; and the rate for the circle of the carpel to contain the greatest number, as in the Malope and Malvaceae. The regularity of monocotyledonous plants with perfect individual flowers has regular homogeneous flowers, and the flowers of the monocotyledons plants this is relatively rarer; the outermost and innermost circles have usually fewer members. Again, respecting the number of circles which follow one another, no general state-
Orchis, Delphinium, Pomaria, &c. The formation of the spur is frequently conjoined with the formation of a symmetrical flower, where one upper or lower foliar organ forms a spur. The flattened expanded form, which is connected with the axis by a linear prolongation, frequently occurs on the sepals (1). This expanded surface is termed the limb or blade of the leaf (lamina); the narrowed base is not termed petiole but claw (unguic). The true articulation is frequent between the foliar envelopes and the tube, but it never occurs in the continuity of these leaves (1); therefore there are no true compound petiolate leaves, though a simply divided limb is frequent, as the petals palmitatia in Rosella, the sepals of Helonias, and the true articulate sepals in Ophrys. The indication of true articulation may probably be afforded in the separation of the upper part of the tube of the flower in Mirabilis, of the calyx of the Datura from the lower, and in some similar cases.

The tubes are not met with in the floral envelopes, but appendages analogous to the ligula appear, which indeed is a part of the structure described as the corona belongs. As in the Narcissus and the Lycoris, the scales of the throat of the Boraginaceae also belong here. These parts are formed in various fashions on the floral envelopes, and such appendages are sometimes exhibited standing upon the surface of the foliar organs, in three or more rows, one above another. Almost all parts recognised as corona and accessory corolla (paraphyses) are composed of these elongated forms exhibited in the Scopolieae and the Passifloraceae; so also does a portion of the so-called nectaria, as, for example, in the petals of Ranunculus. All these are more or less dependent appendages of the foliar organs, which are developed from the flat, adjacent or opposite organs being produced from them subsequently. Here also occurs the one-sided development of a foliar organ; this is seen frequently in the petals of the Apocynaceae (Vinc, Nerium, and Cercis).

The collective form of one or more circles, whether conical or flat, is more accurately designated according to further peculiarities, as tubular (tabulose), bell-shaped (campanulatum), funnel-shaped (infundibuliforme), saucer-shaped (hypocotyliforme), rotata (rotatum), &c. When the circle is divided, one or more segments may be distinguished.

When all the foliar organs are similarly or nearly similarly developed in a circle of evident form, colour, and structure, they are described under the general name of perianth, the single organs of which are called perianthial leaves. If in the floral envelopes of one flower we can distinguish two circles differing in form, colour, and structure, the outer is named the calyx, its component organs being sepals; while the inner is termed the corolla, its simple petals.

Then if the circle segments, or in other words, if they are distinguished as the so-called epicalyx, the leaves must be distinguished also as the perianth phylla. When between the simple or manifold floral envelopes and the stamens other independent foliar organs occur which exhibit a structure very imperfect and abnormal compared with the floral envelopes, these are termed the corolla, of which it will be necessary to speak further on, among the accessory parts of the flower.

The Perianth consists, according to the preceding considerations, of one or more circles of leaves, which are developed so as to be similar in colour, form, and structure. The following series of its forms may be more minutely characterised:

1. The individual foliar organs are always expanded in a flattened or cylindrical limb and claw, and, at least when they are not coherent, united at the base. They may be green, as in the male flower of Urticaea, or of various colours, as in Thymelaeaceae; they may be firm and solid, and that especially when green, as in Eriogonum. They may be delicate, as in Arctostaphylos; or they may be developed as delicate scale-like leaves (palmis), or bristles and hair, as in the Typhaceae and Cyperaceae. The perianth is almost universally regular, rarely in some Ranunculaceae and Orchidaceae symmetrical; in these cases never (1) perfect, 5-merous or 2-merous. This is then not infrequently developed, hollow (sacculatum in Aconitum, calcaratum in Orchidaceae), and it is commonly the uppermost leaf of the perianth. Its foliaceous portions may be continued into the tube of the flower, as in Paeonia, Helenium, &c.; or in the tube of Ophrys, Urticaea; or of more, as Lilium. The parts are frequently blended with the stamens; in the corollin perianth the tube is sometimes straight, as in Narcissus; sometimes curved, as in Aristolochia. The mouth is mostly notched.

2. Sometimes, but seldom, as in the case in Narcissus, furnished with appendages which form a corona, which however are rare in the perianth, and in free foliages only (1) occur on the lip; the inner circle often bears a beard.

The structure of Periannthial Leaves, is, on the whole, that of very simple leaves, which exhibit no special peculiarities, particularly if they are green. The ramifications of the vascular bundles are therefore simple; the separation into an upper and undervenecharma layer is seldom exhibited; but the epidermis usually. In the coloured and delicate parts of the cells of the parenchyma contain colouring matter. In general the parenchyma is very loose and almost spongy, and is very thin, and the cuticular tissue is very thin, and the cellular cavities filled with air; hence the white colour. The epidermis is less developed in coloured leaves, and more resembles the structure of epithelium; stromes are sometimes present, especially upon the under surface, but the epidermal cells of the upper surface are often reduced to shorter or longer papilles, which give the upper surface a peculiar velvet-like appearance. It is very frequent here to find the secrerated layer of the epidermis (cuticula) regularly and delicately striated (incrustulata) which certainly contributes to heighten the brilliancy of the colour, and perhaps, by its effect upon the rays of light, to the production and modification of the peculiar tint.

Occasionally, especially at the base of hollow parts, no matter in what peculiarities of structure the plant may assume a peculiar structure, to perform the function of secretion of a juice containing much sugar; as, for instance, the nectary at the base of the perianthial leaves of Frutiliaria, very various parts on the labellum of the Orchidaceae, &c. Rarely, there is an interpenetration of many thickened porous parenchymatous cells, as in the species of Banksia and Dryandra (1). In paleaceous perians the spiral and other vessels are not so found in the usually simple vascular bundles, and in hair-like papilles even the vascular bundles themselves are wanting.

The Calyx only exists when a corolla occurs with it; it therefore can never be confounded with it. It is always the outer, or sometimes both, of the two sets of leaves; it has forms very much resembles those of the perianth; perhaps it is not so frequently delicate in structure and colour, as in the Scirpobaccaeae, Musaceae, Batomospermum, Ranunculaceae, Podostemata, &c. Usually it consists of one circle of sepals, more rarely of two (as in the Liliaceae). In each of these circles there are always very simple, oval, or lanceolate, seldom pinnatifid, very frequently broad at the base and tapering to a point, or very small (dentes calycis oblongi); sometimes they appear by means of a disc of scales, or as tufts of hair (the pappus of the Compositae). Appropriately the sepals are frequently of a sort made for concave form. The number of the sepals in each circle is in Monotocodylidae, frequently three, more rarelly four or two; in the Dicotyledons it is either one or two; in the Monocotyledons it is often three or sometimes more. Coherence of the sepals with one another may occur in every way, but never with the corolla and stamens nor with the germens; that is which is so called being quite another condition. Both in free and in coherent sepals, regularity and symmetry are met with; the latter often exhibit the bilabiate structures.

Which has been said of the structure of the perianth applies also to the calyx, only that here green foliaceous sepals are the more frequent. The calyx is only what exists in the inner set of floral envelopes accompanying a calyx, may be compared to a very delicate and coloured perianth. No true corolla occurs perfectly green and resembling the leaves; its series of forms is greater than that of any other of the floral envelopes. In the Monocotyledons it presents in general only simple, round, oval, or lanceolate leaves, very seldom having claws. In the Dicotyledons the forms are infinite, as are also the variety and splendid of the colour. The following are the main points in the structure of the calyx:

1. The individual petal exhibits, on a reduced scale and in a delicate condition, almost every variety of form of the leaf, with the exception of the truly compound. Convex forms are here frequent, such as the hood-shaped, pitted-shaped, or spathulate-shaped; these latter, in free petals of an otherwise regular corolla, as in Fumaria. Fringed and feathered forms, as well as variously lobed petals, are also by no means rare. The limb and the claw are often clearly to be distinguished. Parts analogous to
the ligule, and every imaginable form of appendage, with the exception only of the stipules, occur frequently, and characterize genera and families.

On the whole, it is indispensible to distinguish the simple appendages of the petals from the individual foliar organs. To the former belong the scales (fornices) of the Boraginaceæ, the scales of the corona of the Slénaceæ, the formations generally described as coriæ in the Scopoliaceæ and Moutonieæ, the petals of the Irideæ, the nectaria of the Rhamnaceæ, &c.

The corolla consists of one circle, rarely of two (three series in Berberis), or more (four series in Nympheæ). In Monocotyledons the number of members is equal to those of the vessel system. In the double circle of the Poppæaceæ predominates, though it is sometimes composed of two, or four, or of a greater number in Dryas. The number of members is equal to that of the calyx, or greater; very rarely indeed it is smaller; this last case occurs with Haématæ. Suppression is not infrequent, and sometimes involves all the foliar organs of a corolla at once, as in the summer flowers of many species of Viola, in Lepidium runderale, and in some species of Aeser. The coherence of organs in equal numbers has indeed occurred in the calyx as well as the corolla, but not frequently with the stamens.

The corolla, whether with free or with coherent petals, may be regular or only symmetrical. In the latter the blabiate formation is the most frequent, especially in five-membered circles. In such a way that, according as the upper petal is on the upper or on the side of the flower, the upper lip consists of three or of two petals. In the latter case the two are very often little or not at all coherent, as in Tussiliæ; the so-called radiated flowers of the Compositæ (false daisies) is another form; the upper symmetrical flowers are, for instance—the perronate flowers (corolla personata), in which the upper petals of a coherent corolla are so curved inward that they close the entrance of the tube (as in Anthericum), the incised, a portion of the tube being formed by the true blabiate and the upper mouth-like corolla (corolla ringens), in the Labiatae, in which the two petals forming the upper lip often present a concave form overhanging the lower lip, termed gales; the so-called papilionaceous flowers (of the legumes), in which the upper sepal, leaf, which is broad and large, surpassing the others, is termed the standard (vexillum), whilst the lateral petals, as wings (als), are usually dissymmetrically developed, and the two undermost, very frequently coherent, also developed unequally at the two sides, approach each other in a concave form, so as to form the keel (carina). Sometimes all the petals of the papilionaceous flowers become coherent at the lower side of the tube, and form a tube, as in Trifolium; or individual petals are abortive, &c. The most irregular forms are those of the Labiatae, which appear for instance in the Polygalaæae, the Balsamæaceæ, Tropæolaceæ, &c.

All that was said respecting the structure of the perianth holds also for the structure of the corolla, remembering only the differences which the cells vary in colouring matter, and their distribution in groups is sometimes very remarkable. Very dense texture, in consequence of the presence of much-thickened porous cells, as in the Amarantheæ, is frequent. The structure of the epidermis, and its development into papillo, hairs, &c. is very manifold. Development into surfaces secreting nectar, both at the bottom of concave forms and upon the appendages, is especially common. The petals also occasionally secrete a viscid substance, in consequence of which they adhere to the neck of the vessel, in such a manner as happens at the points of the inner petals of the Pumariaæ.

The Epicalyx is seen where these three separate series of foliar organs are distinguishable in the floral envelope, and it is the outermost of these. There are not many plants which exhibit an epicalyx. In form and structure it much resembles the calyx. It occurs with free leaves (as in Passiflora), and coherent leaves (as in Locateria). Its leaves are seldom delicate, such as are seen in the corolla, but are often dry and membranaceous (as in the Rosaceæ), but generally green and leathery (as in the Malvaceæ).

For an account of the other organs of the flower, see STAMENS; FRUIT, S. 2; STIONA; SEED. For the functions of the flower, see REPRODUCTION IN PLANTS AND ANIMALS, &c.

(Schleiden, Principles of Scientific Botany.)

FOOD. The materials taken into the system of organized beings, and by which their functions are maintained, and out of which their bodies are formed, are called Food. Food in its widest sense is the raw material out of which plants and animals are manufactured. We shall confine ourselves here to the consideration of the food of animals, and of man in particular.

The great cause of the necessity of a constant supply of new matter or food to the body is the waste of the materials of which the blood and organs are composed, during the performance of their functions. The products of decomposition of these substances are found in the form of the various excretions which are thrown off from the body by the skin, liver, kidneys, and bowels. We shall find, then, that the food, the blood, and the excretions, represent each other, that they contain substances of the same nature, and are all composed of the same ultimate elements.

If we take a portion of human flesh or blood, and seek for its ultimate elements, we shall find that, on accurate analysis, they will yield the following elements:—

Few or none of these elements occur in the human body in their pure form; but are combined variously with one another, forming compounds, each possessing very different physical properties and chemical relations. These elements may be divided, for physiological purposes, into two classes; the first four, carbon, hydrogen, oxygen, and nitrogen, being called Organic, while the remainder are called Inorganic elements. The first are called organic elements. They are found universally present in plants and animals, and because no animal cell and no vegetable cell can grow unless the whole of these elements exist. Hence, as they lie at the foundation of all organic existence, they are properly designated by this term. The inorganic elements, though generally present in large classes of animals and plants, are not universal. Man requires phosphorus and calcium in the form of phosphate of lime for his bones; but many of the lower animals contain no phosphate of lime. Sea-animals and plants will not live without chlorine and sodium in the form of common salt; but fresh-water plants, and plants away from the sea-shore, do not require this constituent. The term inorganic, then, is applied to these elements to express their different relation to plants and animals, and will also point out their frequent occurrence in the mineral world. The elements of man's body are not all derived from the mineral world, and are identical with those of inorganic substances.

The carbon found in the human body is of such a form, in its pure state, the diamond—which enters into the composition of graphite and various kinds of coal, and is found in limestones and chalk, forming a part of the atmosphere of the earth and of the rocks are composed. The hydrogen of the human body is the gas which, united with oxygen, forms water, and when combined with nitrogen produces ammonia. The oxygen of the animal is identical with the gas which, with nitrogen, forms a fifth part of the atmosphere, and which, combined with the metals, forms oxides, of which the greater portion of the earth's surface is composed. The nitrogen of the organic world is identical with that which constitutes so large a portion of the atmosphere.

Nor are these elements alone identical in and out of the human body; in all these cases it is found that they possess the same chemical properties, and that their agency in the human body depends on these properties. Thus, carbon and hydrogen are inflammable bodies, and have a great affinity for oxygen, with which they unite, forming carbonic acid and water, giving out heat during the process of union. This very process goes on in the animal body, and constitutes one of the most important functions of the body. The characteristic features of the functions and properties of animal and vegetable bodies depend on the chemical relations of the four organic elements.

These elements never enter the system in their pure form. Carbon, however needed in the animal frame, cannot be appropriated pure; and a man would starve with the Kohl- or Moor diamonds, or the purest gold, were it not mixed with other substances for more digestible forms of carbon. The gases hydrogen, oxygen, and nitrogen, would, any one of them in their pure state, destroy human life; and even when the two last are
mixed with the atmosphere, they will not support life in that form. Again, we can see them and not in some more successful. Carbon combines with oxygen to form carbonic acid, and hydrogen combines with nitrogen to form ammonia, and these two compounds unite together to form common smelling-salts, or carbonate of ammonia. But even two chemicals, with all that they contain all the organic elements, will not serve for human food. Nevertheless what is not food for man is nutriment for plants. Carbonic acid and ammonia supply plants with materials of growth. It is from these two bodies that the vegetable kingdom elaborates all the substances which give to plants elegance of form, beauty of colour, deliciousness of scent, deadliness as poisons, and nutritiousness as food. The plant stands between the mineral and animal kingdoms, preparing for the former the sap which is the root of plant life, and for the latter the materials to build up human animals. In the whole range of natural history we are presented with no instance of an animal existing directly on mineral matter. It is true that many animals are carnivorous, and live on the flesh of lower animals. The lion and the tiger prey upon the deer and the antelope; but if we go one step further we still arrive at the vegetable kingdom as the source of animal nutrition. The deer and the antelope are herbivorous creatures, and the flesh of their body is formed directly from the plants they eat. So with the animals eaten by man; all game are herbivorous animals, and supply to man the materials they have obtained from the vegetable kingdom. At the same time the best standard we can take of food is milk, which is derived from the animal. When human milk is examined, it gives the following results in every 1000 parts:—

These five constituents of milk may be regarded as typical of all kinds of food, whether obtained from the animal or vegetable kingdom. Hence we may class alimentary substances according as they are represented by one or other of these constituents of milk.

1. **Aqueous.** Water is required not only as the medium of conveying the other substances into the body, but it forms a prominent constituent of the body itself. Blood contains 790 parts of water to 210 parts of solid matter in every 1000. Muscles contain 770 parts of water to 230 parts of solid ingredients. The brain and nerves contain about 800 parts of water in 1000. If food does not contain water naturally, it is taken into the system in the form of tea, coffee, beer, and also in its pure state. The quantity of water taken in in the form of drink should be about in the proportion of four to one, as we find it in milk. We cannot however judge of the quantity contained in solid food till we know its composition. Thus many substances which appear solid contain a large quantity of water. In potatoes, for instance, there are 75 parts of water in every 100.

2. **Oleaginous.** The butter of the milk represents oily and fatty matters in general, which seem to enter into the composition of all healthy food. They are taken by the inhabitants of tropical countries in the seed of the cocoa-nut, as well as by those of the polar regions from the fat of the seal and many kinds of fish. They are obtained from both the animal and vegetable kingdoms, being known by the name of fats and lards, from the former source, and oils and butter from the latter.

3. **Saccharine.** The sugar of the milk represents several substances obtained from plants and used as food. Sugar itself varies in its composition according to its sources; hence we have cane-sugar, grape-sugar, maple-sugar, &c. Sugar has also a composition of a very different kind, starch, and this substance is very generally found in the vegetable diet of man; pure in the form of arrow-root, tapioca, and sago; combined in the flour of wheat and other cereal grains. Carbohydrate is the name applied to these animal products used as food, sugar is found alone in milk.

4. **Proteinaceous.** The casein of the milk, which, when separated, is known by the name of cheese, has in common with some other animal substances, called fibrine and albumen, a principle which we may term Protein. These substances form the chief part of the fabric of the body, and in their capacity of food perform a very different function in the body to the butter and sugar before mentioned.

5. **Inorganic.** The salts of milk are the saline substances which, entering into the composition of various parts of the human body, are necessary to its integrity and health. The importance of the presence of these substances is frequently overlooked, in food, and many serious cases of the human frame arise from their absence. They are conveyed into the system by both animal and vegetable food; but in common salt we have an instance of a substance belonging to this class taken directly from the mineral kingdom as food without the intervention of an organic body.

In addition to these forms of dietetic substances found in milk, the food of the adult human being constantly contains certain principles which do not appear to be represented in the above. Some of the substances called condiments, as the various spices, contain volatile oils, which, although not essential to the diet of man, seem to exert a very beneficial influence when taken into the system. In tea and coffee there is a principle called thein, which seems to be the active ingredient of these substances. In the fruit of plants also, we have acids, as the citric, tartaric, malic, and oxalic acids, which seem to act very beneficially in certain states of the system. As these substances seem to act medicinally rather than dietetically, they may be properly called, as a class, the medicinal constituents of food. The following classification will give an idea of the kinds of food:

**Class I. Alimentary Substances.**

**Group A. Aqueous,** containing water as a principal ingredient.

- **Examples:** Tea, coffee, beer, wine.

**Group B. Carbohydrates,** containing carbon as a distinguishing ingredient.

1. **Saccharine.**
   - **Examples:** Sugar, starch, cellulose.

2. **Oleaginous.**
   - **Examples:** Oil, butter, fat.

**Group C. Nitrogenous,** containing nitrogen as a distinguishing feature.

1. **Vital.**
   - **Examples:** Flour, oatmeal, maize.

2. **Animal.**
   - **Examples:** Butcher's meat, cheese.

**Group D. Inorganic.**

1. **From organic sources.**
   - **Examples:** Potash in fresh vegetables, phosphate of lime in flour and flesh.

2. **From the mineral kingdom.**
   - **Examples:** Common salt.

**Class II. Medicinal Substances.**

**Group A. Acids.**

- **Examples:** Citric acid in oranges, tartaric acid in grapes, oxalic acid in rhubarb-leaves.

**Group B. Volatile Oils.**

- **Examples:** Mustard, pepper, nutmeg, cloves.

**Group C. Alkaloids.**

- **Examples:** Theine in tea and coffee, theobromine in chocolate.

We shall here make a few general remarks on the nature of the substances in the groups indicated, referring for special information on the plants and animals yielding food to the various articles devoted to these subjects throughout the 'Penny Cyclopedia,' and its Supplements.

Under the head of Wazas will be found an account of Water and the substances it usually holds in solution. In taking it as an article of diet, the following general remarks should be borne in mind:

First, it may be taken in too large quantities to be carried off by the other excretory organs, and then it remains in the system to impoverish the blood, and to reduce the amount of solid matter that is necessary for the performance of the functions of the tissues of the body. This is one of the results that take place from what is called the 'water cure.' Unless persons have sufficient vigour to take the exercise necessary to throw off by the skin the water that is taken into the stomach, serious ill effects must necessarily arise. The good that is effected by this system of the treatment of disease must be attributed more to the exercise it renders necessary than to the unnatural quantities of water taken into the body.

Secondly, Water may not be taken in sufficient quantities to carry on the healthy functions of the system. If the food is taken too dry, it is only imperfectly digested, and many important constituents, such as the salts, are not taken into the blood in sufficient quantity. A deficient quantity of water in the blood will also prevent the healthy process of nutrition, and wasting and degeneration of the solid parts of
FOO 237  FOO

The body will occur. It would be difficult, perhaps, to lay down any law with regard to the quantity of water individuals should take, and perhaps it is safer to rely on the instinct of the body itself. Our modern methods of cooking, of course, only serve to increase the feeling of satiety that comes on after enough has been taken. We may, however, get at something like an approximation of the proportion of solids and fluids required by the system in food, by examining the composition of food, and what is known as the food value of the various parts. As is 870 to 130 in 1000 parts, or about seven to one.

Thirdly, the good effects of water may be destroyed by the substances with which it is taken. Although the stomach has the power of separating water from the food in which it is contained, if it be done too fast, the parts that are of vital importance are injurious. Water itself may contain a large quantity of saline matters, or of organic matters in a state of decomposition, as to cause serious disease. The taking habitually water in the form of fermented liquors, as beer and wine, as well as the admixture of dissolved spirits, may cause irritation and congestion of the mucous membranes, and derangement of the nervous system.

We now proceed to speak of the Carbonaceous Group. This class of substances is sometimes called Respiratory and Combustible. They are called respiratory, because it is through the function of respiration that they become useful in the system. They are called combustible, because it is through the process of combustion that their effects upon the system are produced. It is, in fact, a fact, that, fact, contribute directly to the nutrition of the body, but they are consumed in maintaining the animal heat. The temperature of the body is always a fixed one; and it is not the temperature of the whole body, but the temperature of the arm, or in any other unexposed part of the body, we shall find that it stands at the point in the index of Fahrenheit's thermometer marked 98.6. This heat the body main-

The human body is preserved at the same temperature by the regulating action of the skin. When large quantities of heat are generated in the body, by exercise or other causes, then the extra heat is carried off by the perspiration from the skin. The skin is a vast surface, and its heat is rapidly conducted away by surrounding cold, the heat is maintained by increased supplies of food belonging to the carbonaceous group. The animal heat of the lower animals varies according to the season of the year. Those performing great muscular exertions, and living in cold climates, have a higher temperature than man; whilst those which are not active in their habits, and live in hot climates, have a temperature lower than that of man.

The substances belonging to this group which enter into the food of man are cellulose, starch, sugar, and oil.

Cellulose forming the external membrane of the cells of all plants is found in all food derived from the vegetable kingdom. It has a composition almost identical with starch, but differs from starch. If there can be little doubt, however, that it is taken up extensively into the system in the food of the lower animals, especially of the Herbivora. When cells are very thick with cellulose they are indigestible, and this will account for many articles of food as carrots, turnips, radishes, uncooked vegetables, &c., not being readily digested. Cellulose is converted into starch by the addition of sulphuric acid, and it is not improbable that some change of this sort may take place when it is taken up by the body. It is not probable that it is utilised by human beings alone, although recommended by no less an authority than Benjamin Franklin, who showed by example that saw-dust puddings might be used as an article of diet.

Starch enters the body in the forms of roots, of man, and of the lower animals. It is distinguished from cellulose by its ready diffusibility in water. On this account it appears to be much more readily absorbed from the stomach or converted into the forms in which food is taken up into the system. Its property of mixing with water and forming with it as a high temperature a gelatious mass, explains the change which takes place in boiling the flour of the grains in which it is contained.

Starch is found in some plants in greater quantities than in others; it is however very generally found in the roots and rootstocks, in the stems and in the seeds of plants. There are few or no vegetables or parts of plants that are eaten that do not contain starch. It is found in turnips, potatoes, carrots, peas, wheat, barley, oats, and the rest of the Cereals; in coffee, chestnuts, hazel-nuts, and all other seeds; in the apple, the pear, the plum, and cherry, and all other fruits. In many of these things however it is not the distinguishing alimentary ingredient, but in the form of a base in the composition of a part of die. The substances in which it occurs pure arearrow-root, sago, and tapioca.

What is sold under the name of arrow-root in the shops, is a form of starch procured from the rootstocks of various species of plants belonging to the family Aracnoideae. There are three kinds of arrow-root known in the shops, the West Indian and the East Indian arrow-roots, and Tons les Mois.

Although there is much difference in the price of arrow-root, its composition is always the same. Even the substances used to adulterate arrow-root, as potato and sago starch, are of the same composition; and though the appearance and flavour of the arrow-root may be impaired, its ultimate dietetical action is the same.

Although, tapioca starch and potato starch, are all composed of the same constituent, their flavour is very different; hence the preference given to arrow-root as an article of diet. This flavour depends on some peculiar principle, which is not obtained in the tapioca starch is obtained, and by very careful preparing can be entirely got rid of. Arrow-root is used for making cakes, puddings, and a thick gelatious fluid in great request in the sick room. It is a property of starch to combine with water at a tempera-

Starch is one of the commonest articles of diet, and the whole family of starches renders it very useful in cookery, and seems to increase the digestibility of the starch itself.

Arrow-root is frequently regarded as nutritious; but it will be seen that it is not nutritious in the proper sense of the word. Those foods can alone be called nutritious which contribute to the building up of the fabric of the body by adding those materials to the tissues which are being constantly removed by the wear of the body. Now, starch does not perform this function; and, we believe, in the body in maintaining its animal heat. Arrow-root however and the other forms of starch, are frequently mixed with nutritious matters, such as milk and bread; and in this way the food into which they enter becomes nutritious.

Sago and tapioca is another article of diet. Those starches obtained from the inside of the trunks of palms, and other trees. Many plants yield starch in their stems, which, on being prepared, is called sago by Europeans. The sago which is sold in the shops of London is in the form of flakes, and is an article of the Indian Archipelago, and is the product of a palm called the true Sago-Palm, or Sagesa lariis. There is however another palm belonging to the same genus, the S. Rumphiis (the Prickly Sago-Palm), which yields the sago that is consumed by the natives of India.

Sago is not generally so carefully prepared as arrow-root; and it is a much cheaper article of diet. Its ultimate action is perfectly the same as arrow-root. It is now often employed by the arch-meatman to procure the finer kinds of starch used by the cultivated classes. When thus prepared, it is used to adulterate arrow-root.

Tapioca is another form of starch. It is brought to Europe from South America, and is the produce of a plant known to botanists by the name of Manihot Esculenta. It is a poisonous plant, and the Indians in the countries where it grows extract a poison from it, which they use to poison their arrows, before they obtain the starch. Cassava, which is eaten by the natives, is procured from the same plant, but is prepared in a different way. The most important difference between the two lies in the chemical composition from that of sago and arrow-root, and it is used in the same way, and for the same purposes.

There are many other well-known plants which owe their value to the starch they contain. Among these we may mention the potato, the carrot, the turnip, the parsnip, the cabbage, the Jerusalem artichoke. From some of these we may mention the potato, the carrot, the turnip, the parsnip, the cabbage, the Jerusalem artichoke. From any of these starch might be prepared. The roots of Arum maculatum, though acrid, contain much starch. When cooked the acridity of the plant is got rid of, and they are
eesculentum). The part of the plant which is eaten is the thick middle rib which runs through the frond. It is sometimes called Chinese Moss.

6. The Dulse of the south-west of England is the Fruticis culitis of botanists. It is eaten by the fishermen of the south-west coast of England, where before eating it pinch it between red-hot irons. In Scotland it is cooked in the frying-pan. It is said to be good when it has been exposed to the atmosphere after a long sea voyage.

6. Dulce of the Scotch, Delik, Delihan, Dulieger, Water-Lef (Rhodomenia palmata). The Highlanders and the Irish, before the introduction of tobacco, were in the habit of drying this weed and using it as a masticatory. The Welsh use it for the same purpose. It is a species of Laminaria, and is sometimes called Kelp. The Atlantic Kelp is, perhaps, the best known species, and is the species which is most commonly used in this country. It is now almost entirely disused in Great Britain.

7. Starch differs in some of its chemical and physical properties according to the plants whence it is obtained. In this work, it is distinguished from the gums and the sugars. Starch is a form of starch obtained from the Inula Helenium, a plant not uncommon in our own fields. Lichen-starch is another form, which is found in almost all kinds of Algae as well as Lichens. This starch has the same power of thickening water at a high temperature as arrow-root and tapioca, and, hence, when any of these plants are boiled in water, they form a thick mucilaginous decoction. The thickness of the fluid thus obtained, under the erroneous notion of its being nutritious, has given rise to the name of many species of sea-weeds and lichens as articles of diet.

8. One of the plants of this kind, which has been most extensively and is still largely employed, is the Iceland-Moss (Cladonia Isodactyla). It belongs to the family of Lichens, and forms part of the province of the Komplex. This and other lichens probably contain other dietary secrets besides starch, as we find they are capable of supporting animal life. The Reindeer-Moss (Cetraria Rangiferina) is an instance of this. In the northern parts of the world as well as in the south, it constitutes a principal component of the food of the reindeer. There is also an article called the tundra-starch, which is sometimes consumed by the Eskimo for many feet. The Cup-Moss (Cladonia pyxidata) of our own moors belongs to the same genus as the reindeer-moss, and is also used as an article of diet in the same way as the Iceland-Moss. It is the tundra-starch of many of the northern lichens which has been used as an article of diet. There is a melancholy interest attached to it, as it has so often formed the chief article of diet of our arctic navigators. Two species of lichens, the Gyrophora proboscidea and G. crocea, afford the Frie de Roches. Although they are said to be nutritious, they are described as having bitter, nauseous, and purgative properties.

9. Amongst the sea-weeds which have been used as articles of diet are the Kelp Crowns, that is the Chondrus crispus, under the name of Carragena-Moss, and on the west coast, the Pearl-Moss has had a long time used in Europe. It grows on the rocky sea-shores of Europe; and when washed and dried, and then boiled with water, makes a mucilaginous decoction, like the same preparation of the Iceland-Moss, has been recommended in consumption, coughs, diarrhoea, and other diseases. It has however no bitter principle, and is probably less tonic than the lichen. This and other sea-weeds have occasionally had recourse to by the poor inhabitants of the sea-shores of Europe, more especially Ireland, when the ordinary corn or potato crop has failed. They contain however but little nutritious matter, and persons soon famish who live upon nothing else. There are certain preparations of sea-weed which are often eaten as an addition to other kinds of food. There is in all of them a certain flavour of the sea, arising probably from the saline matter they contain, which renders them very objectionable to some persons as articles of food, and which will probably always be an objection to their general use. Of those which are eaten in various parts of England we may mention:-

1. Laver, Sloke, Slomak (Porphyra fasciata). It is on all the Shetland Islands, and when employed as food is salted and eaten with pepper, vinegar, and oil.

2. Green Laver, Green Sloke, Oyster-Green (Ulva latissima). The Ulva is not so good to eat as the Porphyra, and is only had recourse to when the latter is not abundant.

3. Sea-Gradilla, Sea-Wand, Red Weed (Laminaria digita). It is cooked by boiling for a long time, and adding pepper, butter, and lemon-juice. Cattle are fed on it when young in some parts of the British islands.

4. Badderlochs, Hon-Ware, Honey-Ware, Murlia (Alaria)

6. The common form of sugar in plants, and that which is most frequently eaten in diet, is Cane-Sugar, so called from its being yielded by the sugar-cane. It consists of-
The other kinds of sugar which are eaten, are milk-sugar, \( C_{12}H_{22}O_{11} \cdot 3 \cdot SHO \); and grape-sugar, \( C_{12}H_{22}O_{11} \cdot SHO \). It will be observed that the sugar is in the same position, and it is probably formed in the plant from that body. Although cane-sugar is found in the sugar-cane, the beet, and the maple, it is not so prevalent in plants as grape-sugar, which is the form in which sugar is found in the fruits and other parts of plants which may be sweet.

The sources of sugar, as an article of diet, is of course very various; it is only separated however from a limited number of plants. Of these the principal is the Sugar-Cane (Saccharum officinarum). This plant bears luxuriantly by the inhabitants of France is principally obtained from the Beet (Beta vulgaris). In tropical countries it is obtained from the juice of palms, as from the Jaggery Palm (Carpopterus urens), the Cocos-Nut Palm (Cocos nucifera), and others. It exists in the stems of all grasses, and is prepared in America from Maise (Zea Mays). The Birch (Betula alba) in this country, and the Sugar-Maple in America (Acer saccharum), also yield it in their sap.

Grape-sugar, also called Glucose, is found in the fruits of most plants. It seems to act on the system in precisely the same way as cane-sugar.

The result of the fermentation of grape-sugar is the production of Alcohol, which does not differ much in composition from sugar. The following is the decomposition:—

\[ C_6H_{12}O_6 \rightarrow 2 \text{ Atoms of Alcohol} + 2 \text{ Atoms of Carbonic Acid} + 2 \text{ Atoms of Water} \]

One Atom of Grape-Sugar 12 14 14

Alcohol is taken as an article of diet in the form of beers, wines, and spirits. Although resembling sugar in its composition, its effects on the system are very different. It acts on the nervous system as a stimulant. It might perhaps be regarded as one of the medicinal forms of food. A question has arisen amongst physiologists as to the action of this substance on the system. Liebig, and with him many others, maintain that, like starch and sugar, all the products of the combustion of the system, and thus by combustion assist in maintaining animal heat. On the other hand Dr. Carpenter, and those who repudiate the use of alcohol in diet, maintain that it is not destroyed during respiration, and consequently does not promote animal heat any further than as it stimulates the heart’s action.

Alcohol when taken as an article of diet not only acts upon the nervous system, but on account of its chemical action as a stimulant it is extensively taken in large quantities upon the mucous membrane of the stomach. It is thus that when indulged in, it becomes a source of indigestion, and lays the foundation of serious diseases. Taken in small quantities in the form of wine or beer, being seen to act only upon the digestive function, and to belong to that class of foods to which spices and condiments are referred. Taken medicinally it is often capable of exerting powerful effects, on account of its rousing action upon the vascular system. It does not seem to be necessary to health, as there are many nations that never use it, and individuals, in countries where it is habitually taken as an article of diet, find their health not materially injured by debarring themselves from its use.

The quantity of alcohol contained in fermented beverages varies very much.

With regard to wines, when the juice of the grape contains large quantities of sugar in comparison with the water, and the fermentation is complete, then the alcohol is abundant, and strong wines are produced; whilst, when the sugar is in small quantities, or the fermentation is incomplete, weak or thin wines are the result. Ports and sherrys are strong wines, whilst those of the Rhine are generally weak.

Sweet wines are those in which all the sugar is not converted into alcohol; the most famous of which are made from other fruits besides grapes. Hence the well-known sweetness of what are called British wines. This does not however arise from an imperfect fermentation, but from the addition of other fruits not being tartaric acid. One of the most remarkable properties of tartaric acid is that it forms an insoluble salt (the cream of tartar) with potash, which is generally found in fruits; and in wines made from the grape this salt falls to the bottom of the cask, forming the tartric or lees of the wine. But other acids, as citric, malic, and oxalic acids, are not thus precipitated from their solutions, and they remain in wines, giving them a very acid flavour, which would render them unpalatable. Alcohol is added to cover their acidity. Sweet wines are objectionable as articles of diet, on account of the sugar they contain, which, when held in solution in wine, seems more likely to decompose, and thus prove injurious to the system than other forms.

In wines made from other fruits besides grapes, the acid is also liable to objection.

Effervescing wines are those which are bottled before the fermentation is complete, so that a large quantity of the carbonic acid, or the other substances left in the wine, is dissolved in the solution in the wine, and escapes when the bottle is uncorked. Such is champagne. Effervescing wines are more liable to disagree with delicate stomachs than others, and the account of their imperfect fermentation rendering them liable to further change in the stomach; and this change is generally communicated to the substances used as food contained in the stomach.

The skins and stalks of the grapes, if not the juice, contain taraxin, a powerful astrincent, and its presence seems to be the cause of the astrincent character of many red wines, as port, claret, and others. There is also a difference in the quantity of free tartaric acid contained in wines; and those which have the largest proportion of this constituent are the sweeter and flavoured wines. Some of the wines from grapes are so sour as to be very unpalatable; this is more especially the case with the poorer white wines of the Rhine.

The quality in which wines differ from each other most is what is called their bouquet, or flavour. It differs in wines made from different kinds of grapes, and differs in the same grape in different districts and in different seasons. It is well known that the vintage of one year produces a better or worse wine than that of another, and thereby affects the development of the peculiar flavour of the wine. Liebig says that the bouquet is dependent on an acid which he calls orananta, and which, combining with the alcohol, forms an ether which gives the odour and flavour to wines.

The quantity of alcohol in wine differs very much. The ports and sherrys consumed in England contain the largest quantity. But then much of this is added. It is added in the form of brandy. Brandy wines keep best, but are not the best to drink. Unless wines are naturally strong, they will not keep, without the addition of brandy. Claret, hocks, and Moselies, are seldom brandied. Some of the hocks do not contain more than seven per cent. of alcohol, whilst port and sherry contain twenty-five per cent.

Arobert Mallet, in his having been submitted to distillation after the fermentation, which produces the alcohol. Brandy is distilled from wine; and peach-kernels, or other vegetable matter containing oil of bitter almonds, are added to give it a flavour. All the species of the genus Prunus, and especially the apricot, sweet cherries, called Amygdalaceae, contain oil of bitter almonds. Rum is distilled from malasses or treacle in the West India Islands, and pine-apples are added to give a peculiar flavour. Gin is distilled in Holland, from rye; in this country from wheat, the grains of which are allowed to become saccharine, and then fermented. Juniper berries are employed to give the peculiar flavour to gin. Whiskey is distilled from wheat, barley, or oats, treated in the same manner as for gin.

Nothing is added to flavour it; but the smoke of the peat, by the aid of which the distillation is effected in both Ireland and Scotland, gives a characteristic flavour to this liquor. Liqueurs belong to this division; they are distilled spirits containing large quantities of sugar, and are flavoured with all kinds of substances, as celery, bitter almonds, gentian, wormwood, &c.

Beers, ale, and porters, differ from wines in the addition of a bitter principle, most frequently the hop, to the fermented liquor. The saccharine matter for fermentation is obtained through barley. The grain of barley is steeped in water, and allowed to germinate. When the starch of the grain is converted into sugar, it is submitted to heat, and malt is formed. The malt is placed in boiling water, and when the hops are added, the wort is allowed to take place, and the beer is completed. When the malt is slightlycharred during the process of drying, it gives a dark colour to the beer. It is then called porter. These fluids vary much in strength and bitterness, according to the quantity of malt and hops employed.
Beer is the safest of these beverages for habitual use; but even this may be indulged in too freely, and disease may be the result. Of the various kinds of beer, that which is to be most commended, is the weak form of bitter ale, which is now so generally employed in the households of London, and is not only a digestive, but a restorative, and a tonic, as it possesses, in its bitter principle, as well as a stimulant, and is frequently, on this account, found to be a valuable addition to the ordinary diet.

The Oligoein group of foods is somewhat peculiar. They are taken in various forms from both the vegetable and animal kingdoms, and are known under the name of butter, oil, lard, suet, fat, &c. The following formula will express the composition of this class of bodies:

<table>
<thead>
<tr>
<th>Element</th>
<th>Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Carbon</td>
<td>11</td>
</tr>
<tr>
<td>Hydrogen</td>
<td>10</td>
</tr>
<tr>
<td>Oxygen</td>
<td>1</td>
</tr>
</tbody>
</table>

It will be seen that the oxygen is in considerably less proportion than in the foregoing substances of this group, and we may consequently conclude that the hydrogen as well as the carbon is consumed in the system in maintaining the animal heat. This is an important point, as it frequently happens that the value of the heat-giving group of foods is limited by the quantity of carbon alone. That oil has more power in maintaining animal heat than sugar or starch, is seen in the fact that it is eaten in larger quantities by men who live in cold regions than by those who live in the warmer parts of the globe. Just as the direct effect from the tropics, man adds oil to his food according to the degree of cold to which he is exposed.

Fats are also deposited in the tissues of man and other animals as a reserve of food in times of fasting. When they fail in their natural food. Thus the Ruminantia get fat in summer to supply them with their winter's store of fuel. Hibernating animals, which are fat when they commences their sleep, wake up quite thin. Their fat has been exhausted in maintaining their animal heat during hibernation.

Oil performs another function in the system. It is very evident from its general presence in every tissue of the body that it has an action in connection with the development of the proteaceous tissues. It seems to assist their development, to act as a kind of preparation for their growth. In this way its curative action in certain forms of disease may be explained. There is no doubt of the beneficial action of cod-liver oil in scrofulous diseases, and its action can only be explained on the above supposition. In connection with the use of cod-liver oil it may be stated that animal oils appear to be in a different physical condition of aggregation from vegetable oils, and are certainly more readily digested and assimilated by the system.

The vegetable oils chiefly used as food are those obtained from the Olive (Olea Europaeus) and the Almond (Amgadalis dulcis). Many seeds, as the Cocoa Nut (Cocos nucifera), Sesame (Sesamum), Chestnut (Castanea), Walnut (Juglans), Hazel-Nut (Corylus), Brazil-Nut (Bertholletia), contain oil.

The fat of animals is the great source of olsigenous food from the animal kingdom.

We now come to speak of the Nutritious, Proteaceous, or Nitrogenous articles of diet. The substance called Protein is the basis of these. It is the first element that appears in the development of the vegetable cell. It is consequently the universal constituent in plants. It also constitutes the chief material of the tissues of animals, in both kingdoms various forms, and is called albumen, fibrin, and casein, according to its physical and chemical properties.

Some animals derive this constituent of their bodies directly from the vegetable kingdom, as all the herbivorous and granivorous creatures; others derive it indirectly from the plant through the animal, as the various forms of Carinifera. Man obtains his supply of protein from both sources. This has arisen of persons who deny the propriety of man's taking animal food, it may be well to examine the evidence on which his claim to be regarded as a flesh-eating animal rests. We shall dismiss the sentimental objection, that life ought not to be taken as unwholesome because it is the result of suffering. The question is, whether for carnivorous animals to prey upon lower animals is a matter of practice universal, and it is precisely amongst these people that we see the greatest amount of physical power, and moral and intellectual development existing. Amongst these nations, those individuals and classes who partake most exclusively of a vegetable diet, are satiety, intellectually, and morally degraded. It is a well established fact, that amongst those classes who get the least animal food, as also in those public establishments where meat is only sparingly allowed, mortality is greatest, and disease is most prevalent. Of most complete digestion is the diet that can be provided by an exclusively vegetable diet is scrupulous, and when traceable to this cause, the most speedy remedy is the addition of animal food to the diet. There are also many other forms of diseases provoked by the restricted use of animal food, which are for cure but an abundant supply of the needed material. I need not, I am sure, specify facts to verify this statement. The experience of every medical man would confirm it; and there is no surgeon or physician connected with the great medical charities of the country, who has the experience of seeing the ill-effects of a vegetable diet, and the benefit, in such cases, of the administration of animal food.

"Not are we at a loss in accounting for the beneficial action of the flesh of animals as food. From what I have before said, it will be recollected that the muscles and other tissues of animals are composed principally of protein; so that they truly constitute the most nutritious kind of diet. It has also been found, not alone as a matter of general personal observation, but from the experiments of various scientific men, that animal food is more digestible than vegetable food. The experiments to which I allude are those performed by Dr. Beaumont of America, on a man that had received a gun-shot wound in the stomach. This wound never healed, and, enabled Dr. Beaumont to perform the experiments alluded to. By placing various kinds of food in the stomach of this man, he was enabled to ascertain how long each required to digest; and it was found that the flesh of animals was much more digestible than any of the more nutritious forms of vegetable food, as bread, and the preparations of flour.

"Could we not find reasons for partaking of animal food in its proper mode and degree, instead of the extremes of exclusiveness or starvation, such as we should find in the case of the lower animals. To the comparative anatomist it is sufficient that he knows the structure of the teeth, jaws, or stomach of an animal, to tell whether it fed on vegetable or animal food; and when he considers the structure that characterises the one or the other combined, he likewise knows that the animal will require both kinds of food. Let us, then, for one moment glance at the structure of the teeth, jaws, and stomach of vegetable-feeding animals, and compare them with those of animals which feed exclusively on animal food. There is great difference. The ruminants, as the sheep and the ox, as specimens of pure vegetable-feeding animals. On examining their teeth it will be found that they have broad surfaces, made rough for attrition on each other. The lower teeth the grass and grain they eat are well ground before they are swallowed. In order that these teeth may be moved with facility over each other, the jaw, in addition to the up and down movement, which is essential to the reception of the food into the mouth, has a lateral movement, by which the triturating of the food between the teeth may be effected. The food thus prepared passes down a long esophagus, or gullet, into a complicated bag or stomach. In the ruminants, though not in all the vegetable-eating animals, a process of digestion is effected which is called fermentation. The food undergoes fermentation in the stomach, the mastication of the food between the teeth, and its ultimate digestion in the stomach.

"If we turn now to the structure of flesh-eating animals, of which the Carnivora, embracing such animals as the lion, and the tiger, may be taken as the type, we shall find that instead of teeth furnished with broad surfaces, they have teeth with sharp points for holding and cutting their food. Their lower jaw has no lateral movement, but a powerful up and down action. For this reason, flesh animals are said to be well able to make act in dividing their food, something in the way of the blades of a pair of scissors when used in cutting. In passing to the stomach, we find the gullet short, and the stomach small and simple in its form, adapted for food that is readily digested.

"On an examination of these organs in man, it will be found that they are a true mixture of these two classes. His teeth are partly adapted for grinding, while a some of
them are supplied with the sharp projections which are characteristic of the *Carnivora*; thus evidently adapting them for the mastication of both vegetable and animal food. A slight lateral movement of the jaw and a down action is expressive of the subervision of its structure to a mixed diet. In the stomach also we find indications of the same intermediate position in its structure; and the same conclusion is forced upon us, that it is part of the apparatus of the carnivorous animals. Hence we meet with a diet composed of animal and vegetable substances.

"That man can live on food derived entirely from plants, or entirely from animals, is a well-known fact. The natives of many parts of the earth are not true carnivorous whilst the Hudson's Bay Hunter, some tribes in the northern part of the world, and the Guachos of the Pampas of America, seldom or never have vegetable food; but neither the physical, moral, nor social condition of either the one or the other would prompt the suggestion that man has his development exclusively on either vegetable or animal diet. In the various positions in which man is placed in the world, there can be no doubt that the relative quantities of flesh to food derived from plants vary very much with great advantage; but there seems to be no position in which man in health can be pronounced to be the better with abstinence from either the one or the other kind of food. That man does subsist on either exclusively only proves the great range of his appetites. This is made better evident by the fact that it is most nourishing to man when placed on the surface of the earth; but certainly it is no proof of his labouring under a necessity for the supply of one to the exclusion of the other." (Lankester *Letters on Diet*).

Of the three forms of protein referred to above, albumen is found in the flesh and blood of all animals, as gluten in wheat, barley, oats, rye, and the other *Cereals*. Albumen is found in the juices of many plants, as cabbage, cauliflower, asparagus, etc.; it is also found in the nervous system and blood of animals. Casein is present in milk, also in the seeds of leguminous plants, as peas, beans, and lentils.

In the animal body is found a substance called Gelatin, which appears to be formed out of the proteinaceous tissues. This substance is a blooded animal's meat and what cellulose is in the vegetable kingdom, gelatin appears to be in the animal kingdom. Although often taken into the system with animal food, especially in soups and jellys, there appears to be no evidence that it is even converted into a proteinaceous tissue. Experiments on this subject have been performed both in France and Belgium on an extensive scale, and the conclusion arrived at was the same, that gelatin is not used for forming any of the proteinaceous tissues. It is thus almost certain that the hypothesis that gelatin may be appropriated for the purpose of renewing the gelatinous portions of the tissues, which are very extensive in the animal body.

It will be thus seen that although gelatin cannot be said to be an unnecessary food, as it is a part of the really vital parts of the body, it may assist in keeping up certain parts of the fabric. It need not then be rejected from our diet; but it cannot be too widely known, that, as the basis of soups and jellys, it may be administered under the supposition of its being nutritious, and thus lead, if used alone in diet, to disastrous results.

Of the forms of protein which occur in food, Casein demands a short notice. Although, as dissolved in milk, it is very susceptible and becomes, when separated and known the name of cheese, very indigestible. When milk is deprived of its butter, and the pure casein made into cheese, as is the case with some English cheeses, as those from Suffolk, it becomes so hard as scarcely to be digestible. (Guinness.) In the best cases, the butter is curdled with the curd, and a large per-cent of this substance is found in all good cheeses. Stillon cheese is made by adding the cream of one milking to that of another, so that this cheese is less digestible than the better. The indigestibility of separated or insoluble casein will perhaps explain the neglect of beans, peas, and lentils, as articles of diet, although they contain a much larger quantity of nutritious ingredients than most of the other plants. In general remarks upon diet, we present our readers with a summary of the conclusions on this subject arrived at by one of our most recent physiological writers. Dr. Carpenter, in his *Principles of General and Comparative Physiology,* thus concludes this part of his subject:

> "The waste of the tissues, of which gelatin is the basis, may be supplied either by albuminoids, proteinaceous, or gelatinous compounds, since there is no doubt that albumen and casein cannot be added to these. (Pellet.) By adding the first three columns of this table together, and deducting the sum from one hundred, it will give the quantity of water used in each article of food. Thus, taking butcher's meat:"

| Nitrogenous material | 22.3 |
| Carbonaceous material | 14.3 |
| Mineral matter | 5 |
| Water | 37.1 |
| 1000 | 1028.8 |

The quantity of carbon expresses the relative heat-giving power of the food. With foods containing fat the quantity of hydrogen should also be taken into consideration.

</table>

Such a table as this will be found useful in constructing diets for large institutions, which are very often erroneously constituted, and a large waste thereby entailed. The following table contains examples of diets, drawn up by Dr. Lyon Playfair, from various sources. It is here accompanied an abstract of a lecture by Dr. Lyon Playfair on the Food of Man, delivered at the Royal Institution in May 1863. The following extracts from this lecture will explain some of the valuable results obtained by Dr. Playfair.

Dr. Playfair admitted that the health of the nation was due to the combustion of the unsaturated ingredients of food. Man inspires annually about 7 cwt. of oxygen, and about 1-0 lb. of water enters a constituent and produces heat. The whole carbon in the blood would thus be burned away in about 3 days unless new fuel were introduced as food. The amount of food necessary depends upon the number of respirations, the rapidity of the pulsations, and the relative capacity of the lungs. Cold increases the number of respirations and heat diminishes them, and the lecturer tested well-known cases of the voracity of residents in arctic regions, although he admitted, as an anomaly, that the inhabitants of tropical climates often show a predilection for fatty or carbo- naceous bodies. He then drew attention to the extraordinary records of arctic diets shown in the table, which, admitting that they are extreme cases even in the arctic regions, are nevertheless very surprising.

Dr. Playfair then alluded to the second great class of food ingredients, namely, those of the same composition as flesh. Becaria in 1743 pointed to the close resemblance between these ingredients of flesh, and asked, Is it not true that we are composed of the same substances which serve as our nourishment? In fact the simplicity of this view is now generally acknowledged, and athletes, guinea pigs, &c., are now re-named as flesh-formers in the same sense that any animal aliment is.

The old mode of estimating the value of dietaries, by measuring the number of pounds of solid food used daily or weekly, and quite irrespective of its composition, was shown to be quite erroneous; and an instance was given of an agricultural labourer in Gloucestershire, who in the year 1860 the potato famine subsisted chiefly on flour, consuming 168 ounces weekly, which contained 320 ounces of flesh-formers. When potatoes ceased he returned to a potato diet, and now eats 321 ounces weekly, although his true nutrition in flesh-formers was only 8 or 10 ounces. He shows his further advantage by mentioning six pauper diets formerly recommended, to the difference between the salt and fresh meat diet of the sailor, &c., all of which, relying on absolute weight alone, had in reality no relation in equivalent nutritive value.

I think the soldier and sailor, as illustrating healthy adult men, they consumed weekly about 35 ounces of flesh formers, 70 to 74 ounces of carboon, the relation of the carbon in the flesh-formers to that of the heat-givers being 1:3. It is additional to what was already stated above with this it would be found that they consumed less flesh-formers (35-90 ounces), but rather more heat-givers (72-80 ounces); the relation of the carbon in the former to that of the latter being 1:5. The young boy about 10 or 12 years of age required about 172 ounces carboon and half the flesh-formers of the adult man; the carbon being about 88 ounces weekly, and the relations of the two carbons being nearly 1:5. The circumstances under which persons are placed influence the proportion of diet. Employing the workhouse in prisons the warmth renders less necessary a large amount of food fuel to the body; while the relative amount of labour determines the greater or less amount of flesh-formers. Accordingly it is observed that the latter are increased and the former diminished as the amount of work. In the quantity of meat-formers in food we may estimate approximately the rate of change in the body. Now, a man weighing 140 lbs. has about 4 lbs. of flesh in blood, 27-8 lbs. in his muscular substance, &c., and about 0-5 lbs. of nitrogenous matter in the bones. The whole 37 lbs. would be received in food in about eighteen weeks; or, in other words, that period might represent the time required for the change of the tissues, if all changed with equal rapidity, which however is not the case.

"All the carbon taken as food is not burned in the body, part of it being excreted with the waste matter. Supposing the respirations to be 18 per minute, a man expires about 8-99 ounces of carbon daily, the remainder of the carbon appears as waste matter. The substances used as food which we have called medicinal are very numerous. They include acids, volatile oils, and the vegetable alkaloids. The acids are eaten in fruits, such as the citric, malic, tartaric, and malonic acids; volatile oils may be decomposed in the system, and furnish the materials of animal heat. They seem however to perform a more important part in dissolving up the mineral ingredients taken into the system, and forming the necessary substances in the body, by which the carbonic acid acts beneficially when taken in wines, beers, and effervescing waters. Acetic acid, or vinegar, acts probably in the same manner as the other acids.

The volatile oils are added to other kinds of food, and, as condiments and spices, form a conspicuous feature in diet. We may class these, with alcohol, as stimulants of the mucous membrane of the stomach.

The use of tea, coffee, chocolate, and Paraguay tea, in infusions, constitutes a curious class of alimentary substances. They are said to be the most powerful stimulants, the tea, coffee, and chocolate, in every instance, to which the name Thein or Caffein has been given. A substance very similar, Theobromine, is found in chocolate. It is undoubtedly upon the action of these substances that the influence of spirits may be attributed."

Two theorems have been advanced to explain the action of this principle. Liebig suggested that the taurin found in the bile was formed from the waste tissues of the body carried into the blood; and that this taurin was necessary for the production of carbonic acid gas, or rather for the production of the carbo- naceous matter in the system in the form of carbonic acid gas. The taurin must be constantly formed, otherwise the heat of the body is not maintained, the carbonaceous matter not got rid of, and disease is engendered. If persons have not sufficient taurin, or if the digestive organs do not enable them to carry a sufficient quantity of nutrient to the system, the tissus of the body are consumed to form taurin. Liebig had found that their composition was identical with taurin, and so easily as to render it a sufficient substitute for taurin, and thus by the use of them, he supposed we were actually preventing the waste of the body, and so maintaining health at less expense than we could by taking more solid food.

Persons who cannot consume a sufficient quantity of food to yield the carbon necessary for generating animal heat, have recourse to tea, and find it actually a nutritious article of diet; and it is only, says Liebig, "by such means as this that we can maintain our existing population."

If the subject of taurin has been advanced by Dr. Playfair. He says they have a composition very similar to nervous matter. Now, seeing that every operation of the mind must be attended with a loss of nervous matter, there is a necessity for a supply of that nervous matter to enable the mind to carry on its functions. A large quantity of proteinaceous matter would be
required to be supplied to form the nervous matter with proper constituents if taken in by means of meat or bread. But these alkaloids at once become a constituent of nervous matter; and this accounts for the agreeable stimulus and permanent effect on the mind produced by the use of tea and coffee, particularly by studious persons, as well as those whose nervous systems are exhausted from various causes.

In any just estimate of diet the mineral ingredients should be considered. The forms which they assume in the system are not well known, but we have a capital instance in the phosphate of lime, which, forming a part of the bones, we know must be supplied through the diet. This substance is found in the cereal grains, and perhaps one reason that man takes these grains everywhere for the substantive articles of his diet is the possession of this substance. Iron is another substance which is frequently deficient in the blood. It is naturally supplied in the food; but this falling, iron is given medicinally. Potash in combination with vegetable acids seems to have the power of preventing scurrvy. Chloride of sodium is another well-known instance of the necessity of mineral ingredients in the food.

A few plain rules for taking food will properly conclude this article. In the first place, food should be properly cooked. Many substances which are very indigestible when in the raw state are rendered perfectly digestible by cooking. Although the stomach is capable of digesting fruits and seeds of seeds without any exposure to heat, yet, as a general rule, the breaking down of the tissues which occurs in cooking greatly facilitates the digestion of both animal and vegetable food. But whilst this cooking is proper which enables the stomach more easily to reduce the food to the condition of chyle, there are extremes of preparation which however palatable are to be avoided. Food that is much prepared, so as to reduce it to a fluid condition, as soups, stews, and various made dishes, do not present sufficient solid matter for the healthy process of digestion to be carried on. When
the object is to prevent the stomach from doing duty such food is proper. It may also be taken occasionally with advantage as a variety in diet, but food taken long together in this form is injurious.

Much indigestible food at a time should be avoided. Meals of such kind are less digestible than others, and when taken in small quantities are less injurious. It is when such substances are made the principal constituents of a meal that danger is likely to arise. To mention only a few of the less digestible kinds of foods —

Uncooked bread and biscuits, uncooked vegetables eaten as salad, unripe fruits, cheese, pie-crust, fat meats smoked, as bacon, and the fat of meat, some kinds of fishes, especially the Crucianes, crabs, lobsters, etc. Heavy meals of any one of these articles of diet, or mixtures of them, may be very injurious, and produce serious attacks of indigestion, and may even be fatal to persons not otherwise diseased.

Solid food should be well masticated before it is swallowed. The teeth are organs given us on purpose to perform this function, and its accomplishment is attended also with the mixture of the saliva with the food, which seems to be an important step in the process of digestion. Although by hasty mastication persons in business hope to save their time, they should know that at least it is a loss of food, if not immediately a loss of health. Much food is digested when it is well masticated than when it is swallowed very hastily in large masses. Food that is imperfectly masticated is digested with difficulty, and remains sometimes so long in the stomach as to produce irritation of the stomach, and remaining unacted upon it putsrids, producing pain and taints the breath.

Even where mastication is very complete it is always better to swallow slowly, as by this means every part of the food is brought more fully under the action of the pepsin of the stomach, and the acid of the stomach, by which it is prepared for absorption into the blood.

Full and heavy meals should be avoided. It is better to get up to table with some appetite than that no more food could be taken. It is always difficult to show much should be with propriety taken. Some systems will bear twice as much food as others, whilst there are those who require twice as much food as others. Scales and weights are not always in all cases of the same level. How much shall one be satisfied with on what others will thrive. There is an instinct which, if obeyed, constantly cries " Hold, enough," which if men would listen to would always guide them right. The feelings about eating should be those of refreshment and comfort—feelings that are not often present when too large a meal has been eaten. All food taken into the system and not wanted is likely to be in the way, and the processes adopted by nature for getting rid of the incubus are not frequently attended with success.

Persons who habitually over-eat are frequently obliged to have recourse to medicines to correct the errors of their indulgence. Such an unnatural way of correcting the evils of an unnatural habit is itself likely to produce disease in the system.

Active bodily exertion should not be taken immediately after the principal meal. The stomach requires a supply of blood to perform its functions. If the current is diverted to other organs digestion is prevented. On this account reading at meals is an objectionable practice. The brain in this process gets the blood which the stomach requires. Long walks and hard study should both be avoided after a full meal.

Long fasting is bad. It is bad when the body is resting; it is much worse when the body is actively engaged. The stomach, like all other organs, performs its functions in virtue of the stimulus afforded it by the blood. If the blood is allowed to go a long time without a renewal of its constituents it no longer supplies the nervous system with energy to the stomach, and even other organs, flag in the performance of their duty, and as a consequence digestion is imperfectly performed. How often should man eat in the day? In the morning, at noon, and at night, is the answer given by the instincts of man.

The body can go longer without food whilst resting than when awake; hence persons may with safety go a longer number of hours between the night and morning meal than between the evening and noon, or the noon and night meals.

There are no rules without exceptions in certain cases, and there are many circumstances which must modify the application of the foregoing rules, as well as in other ways regulate the taking of food.

Age is a perpetually modifying influence. The new-born infant requires the food which nature has provided for its use every hour or two. As it grows older the intervals at which it takes its food become longer, it should be always rechristened, that as a rule children should have more eating times than adults. Grown-up people are too apt to assume that what is good for themselves is good for children; hence as great an amount of suffering is entailed on children by restricting them to the taking of their diet amount. It is the rich as come upon them from absolute want amongst the poor. The craving appetite of children is no vice of fallen human nature, but the incessant demands of an ever-wasting yet ever-growing human body. Bread and butter, or treacle, or cornflakes or marmalade or any other food for rapidly growing boys and girls between the hours which adults find convenient for their meals. An evil however arising out of the healthy appetite of youth should be guarded against; it is, that whilst growing a habit is acquired of eating large quantities of food which are no longer required when growth has ceased. If the appetite is not checked by reason at this period of life, the habit of eating more than is necessary may be productive of evil results.

Older persons require less food than the adult, though, not in so large a quantity. "A little and often" is a maxim that enables many aged persons to continue their influence in the world, whilst an attempt to maintain the habit of youth and middle age has cost many decline in the vigor of their lives.

The mode of life influences the diet. The sedentary, the inactive, do not consume so much muscle and nerve in their existence as the active and laborious, and accordingly require less food. Hunger is the commonest danger of the day-labourer; and the lady all day in her drawing-room or carriage cannot expect the appetite or the enjoyment of food which is bestowed by the laws of nature on her housemaid.

Other things being the same more food is required in winter than in summer, more in cold climates than in hot ones. This arises from the greater consumption of certain parts of the food in maintaining the animal heat in order to keep the body from a deep freezing. The Midsummer dinner is to run the hazard of a surfeit; whilst the traveller who carries the eating habits of the north to countries under the line frequently perishes of fever brought on by repulsion.

(Moleschott, Physiologie des Nahrungs Mittel; Ward, Science of Health; Food of Man, in Knight's Shilling Volumes; Lectures on the Food of Man, by Dr. Lankester; Letters on Diet, by Dr. Lankester; Pereira, On the Diet of the Poor; Carpenter, Principles of Eating; Healthy, Carpenter, Principles of Physiology.)

FORAMINIFERA (Foramen, foro), a group of minute Marine Animals of low organisation, consisting of a slimy envelope containing a hard calcareous shell; found in sea-sand and amongst marine refuse dredged up from deep water. Owing to many of their shells having a spiral form, these creatures were long thought to be highly organised Mollusca, allied to the living Nautilus, an error into which most naturalists fell until recently, when these animals became the subject of a more rigorous and searching investigation than they had previously undergone.

Though usually very minute, their elegant forms early attracted the attention of naturalists. They were noticed by Guernier, Planchus, and Ledermuller, prior to the appearance of the 'Systema Naturae' of Linnaeus. In the latter work they are included amongst the Nautili, the animal, as well as that of its food, being so much alike; but Linnaeus associates them, being alike unknown to the Swedish naturalist. In the 12th edition are descriptions of 15 species. In 1780 Soldani, an Italian priest, published two volumes of observations on the foraminiferous shells. He divided them into groups (such as Navulli, Hammoniac, and Orthocerata) in the most arbitrary manner; but the works are monuments of his labour and perseverance. In 1796 four remarkable species were described by C. d'Orbigny, as 'Testascula Rario.' The 'British Conchology' of Montague, 1803 (and 'Supplement,' 1808), contained a still larger number of British forms, respecting the majority of
which the error of Linnaeus was still followed; but some were shown to be so different from the true Nausita; as to warrant the attempt to raise each portion to the rank of an individual animal, even in the limited sense in which we should admit such a distinction in the polytypes of a Sertularia or of a Gorgonia, appear to me wholly inadmissible. If the soft structures of the calcareous skeleton, and the less well marked or less perfectly calcified parts of the British Foraminifera, and I have very little doubt that such will prove to be the case, the whole animal will be very little raised above the Polyplacophora, only possessing a smaller symmetry of its articulations, which make it the subject of internal and internal." (Transactions of the Microcopic Society of London.)

In 1846 M. D'Orbigny published his work 'On the Foraminiferous Tertiary of the Basin of Vienna,' in which he also described the 'Polyplacophora.' It was evident that in 1853 he had now recognised the organic relations of these objects to the Cephalopoda, with which he had previously arranged them. He rejected the idea that they were aggregated creatures, as held by Ehrenberg, as also the existence of the intestinal canal and organs of reproduction described by the illustrious Prussian; but he arrived at the conclusion that they held a position intermediate between the Polyplacophora and the Echinoidea.

M. D'Orbigny says, "After what has preceded upon the characteristic of the Foraminifera, the comparison demonstrates that they cannot be arranged in any of the known Zoological Classes. Much less complex than the Echinoidea or the Polyplacophora as to their internal organisation, they are both species of locomotion of the former, and are by their isolated, non-aggregated, free existence, more advanced in the scale than the latter. This individual existence of the Foraminifera, liberty which they enjoy, and their mode of locomotion, are characteristics which take them to a position intermediate between the Echinoidea, to which they are very inferior in all respects. Although less complex than many Polyplacophora, they have not a common aggregate life. A multitude does not unite to form a regular body as among the Polyplacophora. They are entirely locomotive, and their mode of locomotion is complex, and the great regularity of the testaceous envelope of their segments places them far above the Polyplacophora. On the other hand, much less perfect than the Echinoidea, they are very inferior to them in all respects. We believe also, that, because of the nature of their elements the position of the Foraminifera is in the interval (embracement) of the radiating animals of Cuvier, between the Echinoidea and the Polyplacophora, as an altogether independent class of the Foraminiferous Fossils of the Basin Tertiary of Vienna, p. 19.'

There can be no doubt of their great inferiority to the Echinoidea, which possess a distinct alimentary canal, a nervous circulatory and sexual system; and connecting the whole of their collective circulatory and nutritive canals. The discoveries respecting its reproduction by ova, through the agency of medusiform buds, we must conclude that these latter are equally removed from the structureless animals of the Foraminifera. In the preceding argument M. D'Orbigny forgets that the freedom, isolation, and independence, upon which he lays so much stress, are the characteristics of the fixed compound Polyplacophora, in their embryonic or larval states. Consequently this feature, which in the Foraminifera is normal and permanent, betokens inferiority rather than superiority to the Polyplacophora, in which aggregation and fixation indicate maturity and a higher development. The argument drawn from their symmetry is of no value. Nothing can be more symmetrical than many of the sponge spicula; and in the vegetable kingdom the symmetrical plants (Dendroidea) are amongst the lowest forms.

An additional memoir by Professor Williamson, in 1851 ('Quarterly Journal of Microscopical Science,' vol. 1), afforded other and still more striking evidence of the probable correctness of the views he held, and added much furnished by the structure of a species of Faucina, and especially showed that the new growths which added to the thickness of the shell were all applied to its exterior and not incorporated into it. With respect to the gelatinous animal had the power of extending itself over the exterior of the shell, or of retreating to its interior at will, reminding us of the movements of the gelatinous envelope in some of the less highly organised Pogonophora, and described by Rimmer Jones, 'Animal Kingdom,' p. 10.' In 1845 Dr. Carpenter laid before the Geological Society of London an elaborate memoir
on the structure of some interesting fossil forms belonging to the genera Stichostega and Holostega, which with the publication of M. D'Orbigny on the Foraminifera of Cuba, constitute the chief additional works that have appeared on this subject.

The following is the latest classification of the Foraminifera. As has already been marked by some serious imperfections, it is the best that has been hitherto published. The five principal divisions are chiefly based on the variations in the arrangement of the successively added segments.

Order 1. Monostega.—Animal consisting of a single segment. Shell composed of a single chamber. Genera: Cristatella, Dendrita; Orbulina, D'Orbigny; Colonatella, D'Orbigny.

Order 2. Stichostega.—Animal consisting of segments arranged in a single line. Shell composed of chambers superimposed linearly on a single straight or curved axis. No spiral growths—
- Glandulina, D'Orbigny.
- Nodosaria, Lamarck.
- Orthospinella, D'Orbigny.
- Dentalina, D'Orbigny.
- Prondolium, D'Orbigny.
- Lingulina, D'Orbigny.

Order 3. Helostega.—Animal consisting of segments arranged in a spiral. Chambers piled up or superimposed on one another, forming a spiral volute—
- Cristatella, D'Orbigny.
- Planellina, D'Orbigny.
- Robulina, D'Orbigny.
- Pusulina, Fischer.
- Nexterna, D'Orbigny.
- Nodularia, D'Orbigny.
- Assulina, D'Orbigny.
- Siderolina, Lamarck.
- Lanerina, D'Orbigny.
- Operculina, D'Orbigny.
- Endosulina, D'Orbigny.
- Polydoloma, D'Orbigny.
- Peneroplus, Lamarck.
- Dendrilla, D'Orbigny.
- Spirilla, D'Orbigny.
- Cyclolitula, D'Orbigny.
- Litola, Lamarck.
- Orbulina, Lamarck.

Order 4. Eustomostega.—Animal composed of alternating segments forming a spiral. Chambers piled up or superimposed upon two alternating axes, forming a spiral—
- Eucyclos, D'Orbigny.
- Heterostegina, D'Orbigny.
- Cantiana, D'Orbigny.
- Amphistegina, D'Orbigny.

Order 5. Enallostega.—Animal composed of alternately arranged segments without forming a spiral. Chambers disposed alternately along two or three distinct axes, not forming a spiral—
- Dimorphina, D'Orbigny.
- Testitaria, D'Orbigny.
- Polydoloma, D'Orbigny.
- Virgulina, D'Orbigny.
- Bigerella, D'Orbigny.
- Cunulina, D'Orbigny.

Order 6. Agathostega.—Animal composed of segments wound round an axis. Chambers wound round a common axis, each one investing half the entire circumference—
- Uniloculina, D'Orbigny.
- Biloculina, D'Orbigny.
- Filonatica, D'Orbigny.
- Filonatica, D'Orbigny.
- Scribula, D'Orbigny.
- Spirilla, D'Orbigny.
- Triplacina, D'Orbigny.

The simplest type of the Foraminifera (Monostega), presents but a single segment, and is illustrated by the Orbula unispiralis, which is a small spherical shell with a lateral aperture, the interior of which has been occupied by the living jelly to which the shell owes its existence. The beautiful symmetrical Lagenaria, or Flask Animals (Fig. 3), the British species of which have been figured by Professor Williamson in the *Annals of Nat. Hist.,* also belong to this type.

In the order Stichostega, as for example the Nodosaria, Dentulina (Fig. 3), the shell advances beyond the simple type of the Monostega by a process of linear budding. The first cell is usually spherical, as in Orbula, but through the orifice in this primary cell there protrudes as a growth from the contained animal segment, a second segment, usually a little larger than the first, which speedily increases itself in a shelly covering. This new growth is successively followed by others developed in the same way, until the organism attains to its maturity, when it exhibits a series of cells arranged end to end in a straight or but slightly curved line.

In the Holostega, a large and conspicuous group, the segmentation takes place with a spiral bias, producing the nautiloid form of shell which misled the earlier microscopists. Sometimes all the convolutions are visible. (Operculina, Fig. 4.) In others the outer convolution approximates those previously formed, and conceals them. (Cristatella, Fig. 5.) In a third type all the spiral convolutions are visible on one truncated half of the shell, whilst they are embracing on the others (Panjasinga, Fig. 6), thus combining the other two types. Some genera, like the Stichostegus and Helostegus orders, develop on the plan of the latter, up to a certain stage of their growth, when the arrangement of the cells ceases to be spiral and becomes straight (Spirula, Fig. 7), as in the Nodosaria. The orifices penetrating the serpina and connecting the contiguous segments are sometimes single, and at others more numerous.

In the Enallostegus the shell is spiral as in the Holostegus, but instead of each chamber being equilateral, it has a larger and a smaller side, the position of which is alternately reversed as the segments are multiplied. (Cantiana, Fig. 8.)

In the Enallostega the new segments are arranged alternately on opposite sides of a central line, so as to form two parallel, non-spiral, alternating series (Testitaria, Fig. 9), the segments being connected by a single orifice.

The Agathostega present an entirely different aspect, as well as structure, from the rest of the Foraminifera. They are much less transparent than the majority of the other orders, being composed of a material resembling white porcelain, and which presents a rich amber-brown hue when viewed by transmitted light. They are usually more or less oblong, and as each new segment is equal to the entire length of the shell, it follows that the terminal orifice presents itself alternately at its opposite extremities. Sometimes the new segments are spread out in one uniform plane (Spirula, Fig. 10), at other times each new segment instead of being exactly opposite its neighbour, is a little on one side of it; consequently the chain of segments is wound round the
primary central one, as the thread is around a ball of worsted. (Orbiculina, Triloculina.)

In the great majority of the species the interior of each chamber is simple and undivided, but there are some forms, especially amongst the Helicotecta, in which the newer and more external chambers are subdivided either by transverse pillars or by complete partitions perforated by one or more apertures, through which prolongations of the gelatinous substance unite the various segments of the soft animal. (Orbiculina, fig. 11.) Ordinarily but one such chain of communications exist (animal of Rostovia, fig. 13); but in the cases just referred to, there is a great increase in the number of such orifices, so that the septa become completely cribiform. The distribution of these orifices affects the gassination or mode of growth, since it is through them that the new segments are successively formed, the gelatinous substance being extended by a process of budding or sprouting. An increase in the number of such orifices is most common where the consecutive segments present a rapid increase in their size. In the genus Orbiculina, this growth is sometimes so remarkable that the new segments soon form concentric circles, embracing all those previously formed. (Orbiculina complanata, fig. 11.) In such examples the connecting apertures are distributed round the entire periphery, and gassination most probably takes place simultaneously through them all; so that the soft animal, if decalcified by an acid, would present a succession of rings, enclosing one another, and connected together by transverse radiating bars.

but as additional calcarceous chambers are formed, each such addition not only encases the new generation of the soft animal, but extends over all the exterior of the previously-formed shell. The exact way in which this is accomplished is doubtful; but it is probable that the soft animal has the power of covering itself over the shell, and depositing upon its surface addition of calcarceous bands of high magnifying powers. Through these foraminifers, long delicate processes of the soft animal, termed pseudopodia, are protruded. The exact use of these, whether for tactile, probenial, and locomotive purposes, or for the diminution of the nutritive food, or for other purposes, is not at all clear; but they are useful in some degree each of these functions. They may be regarded as analogous to the prolongations which the Protes Animalcule (Amoebae) extends in various directions; only in the Foraminiferous these organs are more delicate as well as more uniform in thickness than in the shell-less creature referred to.

Professor Williamson has also demonstrated the existence in several species of a curious system of intersecaes and accessory canals which run vertically amongst the chambers forming the walls of the shells. (Horizontal section of Pennaria, fig. 14.) These are especially obvious in the genera Pennaria, Opunculina, and Amphistegina. The tubes open at the exterior of the shell, especially at the peripheral margin, either by a few large or numerous apertures. These canals are probably designed to admit water to the interior segments of the animal, with which they communicate through the minute foramina. In some cases the pseudopodia are protruded through each of these canals as are situated in the umbilical region; but these appear to be exceptional instances.

The relations of the Foraminifers to Paleontology render them interesting objects to the geologist. Many of the more recent calcarceous strata chiefly owe their origin to their accumulation, through successive ages, of these minute stones. The white chalk rocks are mainly composed of them; vast ranges of Tertiary strata present the same characteristic features; and though the older limestones have been so altered by pressure and chemical agents that their origin is less clear, there are many indications that they have primarily resembled the rocks of more recent age—an inference that is rendered probable by the great extent to which sediment now accumulating in the bottom of the sea are charged with these little organisms, and in some cases entirely composed of them.

The fossil Foraminifers are chiefly distinguishable from recent ones in the greater prevalence of specimens of comparatively coarse texture. Though very rare, they are brought from Borneo by Sir E. Belcher measuring more than two inches in diameter, the living forms usually range from the 4th to the 14th of an inch. But the Tertiary strata of the earth abound in examples of the fossil genus Nummulite (Nummulina, fig. 16), so called from their resemblance to coins, which vary from 4th of an inch to the size of half a crown. These are often so abundant as to form mountain masses, extending through the Alps, Northern Italy, Greece, Syria, Egypt, and Northern India. The Mokadam Mountains in Egypt, where the stone used in building the pyramids was obtained, chiefly consist of these Nummulites which are known to the natives by the name of Pharaoh’s Pennes.

The structure of the Nummulites has been investigated by Messrs. Jolie and Leymerie, and especially by Dr. Carpenter, whilst the specific forms have been studied by M.D’Archiac. The genus belongs to the group of the order Helicotecta, in which the outer convoluted one apparently embrace the earlier-formed ones; hence it is only by making microscopic sections, or thin slices, that their structure can be fully seen. When such a section is carried horizontally through the centre of the shell the segments present a spiral arrangement; they as well as the pseudopodia are all of different size and consequent great number. In other respects they present few or no essential differences distinguishing them from more recent forms. A still more curious genus, known by the name of Orbulina, occurs in America, Switzerland, and India; but the only known species which it is possible to represent the Nummulites of the Old World. The labours of Dr. Carpenter have revealed a remarkable structure in this
F O R 248 F O R

genius, but one that appears to have some recent representatives.

Forster, F. Forrest, F. Forster, S. 1.

FORBES, EDWARD, a celebrated naturalist. He was born in 1815 in the Isle of Man, where his father was a banker. Without any one to direct his taste, he became a naturalist while yet a child. Nothing delighted him so much as to pack up his collecting basket and set out on the mountain paths of his native isle, where he could hardly read. By the time he was seven years of age he had collected a small museum. His first efforts at naming these objects were made through Turton's 'Translation of the Systema Naturae of Linnaeus,' at the age of fifteen. He had read Burchard's 'Relieque Diluvii,' Parkinson's 'Organic Remains,' and Conybeare's 'Geology of England.' Such was the impression produced on his mind by the perusal of these works, that he ever afterwards despised those who were content to remain, after their travels, with a mere name.

His first attempt at original work was the production of a 'Manual of British Natural History,' which, although it was never published, was the repository of many of his notes even to the close of his life. His habit of drawing the natural history objects which interested him, led him to think of painting as a profession, and with this object in view he studied for some time in the studio of the late Mr. Sass in Charlotte-street, London. This profession did not however comply with his desire to root himself to the earth. In 1832 he repaired to the University of Edin- burgh with the object of studying medicine. Here under the teaching of Professor Jameson and Graham he first became acquainted with the true principles of natural science, and the ardour and desire for the pursuit of knowledge which his acquaintance with the latter imparted to him induced him to become himself an observer and add to the already accumulated store of natural history facts. It was with this feeling that he started with a fellow-student on an excursion into Norway, where he made numerous observations on the rocks, plants, and minerals of the country, and afterwards published the result of his observations in a paper in the 'Magazine of Natural History,' entitled 'Notes of a Natural History Tour in Norway.'

A large portion of his natural history career he had recognised the importance of the dredge as an instrument of his research, and in his hands this simple instrument became as powerful a means of research as the telescope to the astronomer. With it he swept the bottom of the ocean, measured its depth by the character of its inhabitants, and discovered a law for the distribution of marine plants and animals in depth, as strict as the law which regulated their distribution on the altitude of mountains. His early papers, entitled 'Distribution of the Dredgings in the eighth and ninth volumes of the 'Magazine of Natural History.' Much of his student time was spent upon the sea in the neighbourhood of Edinburgh, and scarcely ever did he make a dredging excursion, so new was the operation to the naturalist at the time. But his objects were the increasing collection of natural objects. His attention was not at all however exclusively confined to marine zoology. Plants were always favourite objects, and no student enjoyed more or professed more largely by the botanical excursions of the late Professor Graham. This habit of excursionalising he held constituted a most important element in botanical study, at once invigorating the body, and giving the student a knowledge of the relation of plants to other objects which they could not otherwise obtain. While he held the chair of botany at King's College, London, he never neglected periodical excursions with his students. He was mainly instrumental in 1836 in establishing the Botanical Society of Edinburgh, which he helped to found, and in 1837 he visited Paris, attended the lectures of the Professors there, and worked in the museum and collections in the Jardin des Plantes. In the same year he visited Algiers and the coasts of the Mediterranean. In 1838 he published an account of the 'Molluscs of the Isle of Man,' and in 1839 papers on the 'Land and Freshwater Mollusca of Algiers,' and on the 'Distribution of the Pulmonifers of Europe.' In these researches he was laying the foundation for the enlarged views which he afterwards held forth, with regard to the distribution of the geaptera and geapterid animals and plants in time and space.

His papers from this time became very numerous. The materials he accumulated in his various excursions were truly astonishing. He adhered to paleontology, but a comparatively small proportion of them.

In 1841 he published a 'History of British Star-Fishes,' containing accounts of several new species, with charming descriptions of the habits of these animals, and incidents connected with them, which his own pencil were worthy of a disciple of Bewick. In this year he accepted the appointment of naturalist to H.M.S. Beagle, commander Captain Graves, who was commissioned to bring from Lycia the marbles discovered by Sir John Fenton. He opened up to him. For the first time the resources of a ship of war were placed at the disposal of a naturalist. The result of this voyage was the discovery of the great law, that among marine animals zones of depth corresponded in parallels of latitude. This law was announced at the meeting of the British Association held at Cork in 1843. The detailed results of this voyage were never given to the world, and Forbes always looked forward to the day when a little leisure would permit him to publish in detail his observations and conclusions. But a few years after his death the government offered to purchase from him the manuscripts of his voyages and observations, and he accepted the offer, and his great work was given to the public.

In 1844 he was in Lycia that he contracted the same form of remittent fever which killed one of his companions, the Rev. Mr. Daniel, and from the effects of which he suffered to the day of his death.

When away in the 'Beagle,' he was appointed to the Professorship of Botany in King's College, London, vacated by the death of Mr. David Don. Although he had resolved on a visit to Egypt and a dredging excursion to the Red Sea, the offer of a chair in London was too much in accordance with his tastes to refuse. He new deliberately gave up the more lucrative, and became a naturalist for the rest of his life. He gave his first lecture in May 1844, and in the same year he was appointed assistant secretary to the Zoological Society. Both situations contributed to the development of his genius, and the growth of his scientific reputation, which seemed to systematise his knowledge, and developed his power of communicating its results, the secretariatship afforded him a means of extending his acquaintance with fossils, and the relations of extinct with recent forms of both animals and plants.

These offices however proceeded one more important still, that of palaeontologist to the Geological Society of Great Britain. When the Museum of Economic Geology was removed to Jermy-street, and the School of Mines founded, he was placed at the head of the geological laboratory which was established in conjunction with these appointments from publishing all he had already stored up, he added here fresh stores to his stock of knowledge; and numerous memoirs and papers in the Natural History Journal, the Proceedings of the Zoological Society, and the Transactions of the Geological Society, and the great observing powers and unsurpassed industry. One of the most important of these papers is entitled 'On the connection between the distribution of the existing Fauna and Flora of the British Isles, and the geological changes which have affected their area.' This paper attempts to explain the distribution of the plants and animals of the British Islands, on the hypothesis that they were all diffused from a common centre, and that consequently they must have been disseminated when these islands were continuous with those countries where the identical species are found. He then brings forward geological evidence to support his assertions, and even goes so far as to point out the fact, that at one time, and that for many centuries, there was a direct land connexion between the south-western portions of the British Islands and America.

In 1854 Professor Forbes was elected president of the Geological Society. In the same year he accepted the chair of Natural History in the University of Edinburgh. He was elected president of the geological section of the British Association, which met at Liverpool in September. He died on the 18th of November in the same year. The Edinburgh chair was the object of his highest ambition. The increasing years of life, combined with the disease of the kidneys which he was a student that he might one day hope to fill this honourable post. He commenced the duties of his new position with his usual ardour, laid down a course of action which would have required years of development, but he had barely time to execute the first part of it, when he was seized with a disease of the kidneys which proved fatal in a few days.
Besides the works to which reference is made above, he was the associate of Mr. Hanley in a great work on the "History of British Mollusca," which was published in parts, and completed in 1848. This work is one of the most complete and exhaustive on the subject of our native Mollusca, and all the descriptions were written by Forbes. He contributed several valuable papers and maps on the distribution of animals and plants to the last edition of Spalding's "Phytogeographic and Zoological Atlas." He also indulged in general literature, and the world was somewhat surprised after his decease to find that for some years he had been a contributor to the review department of the "Literary Gazette." His papers were collected together with some unprinted papers by the late Edward Forbes. The third volume of the "Bibliographia Geologica et Zoologica" of Agassiz and Strickland, published by the Ray Society in 1850, contains a list of eighty-nine papers and works supplied by the author himself, and arranged in a chronological order. His contributions to natural history science were perhaps more numerous during the last four years of his life than during any former period of the same length. Few men have laboured more assiduously in the path of natural science, or produced a greater impression on the current thought of those who cultivated the same branches of knowledge as himself; and the time has not yet arrived when a clear estimate can be made of the influence he has exerted upon the time in which he lived.

FORDINGBRIDGE. [HAMPSHIRE.]

FORESTALLING. This offence, long obsolete, has at length, with others of the same character, ceased to exist. [7 & 8 Viet., c. 94.]

FORESTAY-GOT. [MYCENOS, S. 1.]

FORMICA, a genus of Insects belonging to the family Formicidae. It is distinguished by having the foot-stalks of the abdomen composed of a single joint, the mandibles triangular, and the antennae attached at the edge. The females are destitute of a sting. This genus comprises about a dozen British species, the largest of which is the Hill-Ant or Horse-Ant, *F. rufa.* The neuters in this species are about a third of an inch long, of a black colour, with the thorax, abdominal scales, and legs black; the head and the conical nest in the open ground, in woods, &c., amassing together large quantities of sticks, straws, &c. For a description of these nests see Ant. *F. nemorum* is of a blood-red colour, the eyes and abdomen black, and the wings dull at the base. The neuter is similarly coloured, except that the head is darker. The male is black, with red legs. This species burrows in wood, and is one of those which steals the young of other species, rearing them to perform the duties of the nest. Two of the species subject to these marauders are *F. cunicularia* and *F. fusca,* both of which are inhabitants of this country. The latter species is of a shining black colour, with a slight ash tinge; its form is rather long, and it is nearly smooth; the thorax is yellow. The so-called *F. rufa* is a red colour, as are also the legs; the abdominal scale is large and triangular; and the ocelli are distinct. It establishes its nest under stones, moss, &c., and at the foot of trees, the nest being entirely underground. Among the exotic species of this genus are to be found many which are extremely injurious or annoying in their habit. Of these the Sugar-Ant of the West Indies is perhaps the most extensively prejudicial. *F. saccharivora,* as it is called, establishes its nest at the root of sugar-canes, lime-trees, and lemon-trees, where it bruises the leaves so that the trees are either blown down by the violent gales, or so completely deprived of nourishment as the roots that they soon die. Some years ago the injuriousness of this insect was so great that a reward of 20,000l. was offered by the planters to any one who should discover an efficient mode of destroying them, yet nothing could be found to stay their ravages. The aid of fire was even resorted to in vain; the ants were not more than a year or two removed as to extinguishing it. Heavy torrents of rain at last effected their destruction. *F. sинфius,* another exotic species, is described by Colonel Sykes as being an extraordinary instance of the operations of insects for the benefit of plants. These insects for sweet substances is very great, and their attacks on such things were resisted in every possible manner; yet although the table, on which the confectionery and sweets were, was placed with its legs in water and removed a short distance from the wall, they succeeded in reaching them, to the great astonishment of all, until the mode of access was discovered. Colonel Sykes says, "I observed an ant upon the wall about a foot above the level of the sweets; it fell, and instead of alighting upon the table and slitting upon the ground it fell upon the table." Others followed its example with similar success; and it was no longer a matter for doubt as to how they continued to swarm in such numbers about their favourite food, however carefully guarded.

FORMICIDAE, an extensive family of Hymenopterous insects, belonging to the section Aculeata, and to the sub-section Heterogyna of Latreille, comprising the Linnean genus Formica, the largest of all the species of Ants. The family is distinguished by the wingless state of their abortive females, by the great length of the basal joint of the antennae in the females and the neuters, in which they are elbowed at the extremity of this joint, and by the first or the second joints of the abdomen being knotted; the uterus of the neuters is large, horned, and perpendicular, falling between the jaws; the eyes are rounded, or oval and entire; the jaws are large in many of the species, the form of these organs varying greatly in many of the species. In their structural character the *Formicidae* resemble the *Tephritidae* and *Dorylidae* belonging to the section of the Sand-Wasps. The neuters are smaller than the males, and these are smaller than the females; the abdomen in the first and last of these sexes is composed of a single joint, in the middle of the female and neuter are furnished with a sting in many of the species. Those species which have stings emit an irritating fluid into the wounds which they make, while the stingless species discharge a red transparent fluid on to the skin, causing painful ulcers.

The various genera of this family, according to Latreille, are: — *Formica, Polyergus, Poneria, Myrmica, and Atta.* This last genus differs from *Myrmica* only in having very short palpi; the head of the workers is generally very thick. *Apisflata* is the Visiting Ant of the West Indies.

FORMYLE. [CHEMISTRY, S. 2.]

FORRES. [ELGINSHIRE.]

FORSTER, FRANK, civil engineer, was born in the year 1800, near Norwich, and was educated at the Bishops' School. He was resident engineer of the portion of the Chester and Holyhead Railway, from near Conway to Holyhead, including the masonry of the Britannia Bridge, and difficult works in sea-walls and tunnels along the line. On the formation of the Metropolitan Railway Commission in 1845, Mr. Forster was appointed engineer, and was instructed to furnish a general scheme of London sewerage, for which many plans had been sent in to an invitation some time previously. He very soon suffered from the effects of the arduous duties thrown upon him, and which were rendered more difficult by numerous contending opinions and interests. He himself was freely animadverted upon by the press, and was at length compelled to resign his appointment, and died suddenly a few weeks afterwards, on the 15th of May, 1847, in his 46th year. His schemes and plans, with reference to the drainage of the north of London remain, and are understood to have formed the basis of the schemes now under consideration, and in which a partial commencement of work has been made.

FORTOUX, HIPPOLYTE, late Master of Public Instruction in France, was born in 1811. He commenced active life as a literary man by contributions to the 'National,' 'L'Artiste,' and other periodicals. In the earlier part of his career he was closely identified with the French movement. He was befriended by Béranger the poet, of whom, in 1830, he published a biography. He was a contributor to the 'Revue de Paris,' and was an unsuccessful competitor for the editorship of the 'Revue des Deux Mondes.' Meantime, by the aid of his stepfather, a rubber merchant of bath, he began to acquire a small income. He was made Professor of Literature in the university of Toulouse, where he distinguished himself as a lecturer, and was afterwards recompensed for his services by being appointed Dean of the Faculty of Art. He was also admitted into the French Academy in the section of Belles Lettres.
Lettres. After the revolution of 1848 he was elected a member of the French National Assembly, in which he spoke frequently, and obtained the favor of the Prime Minister. Immediately after the close of that he was appointed, December 3, 1851, Ministre d'Instruction Publique et des Saltes, and was one of the six ministers who signed the decree for the confiscation of the estates of the house of Orleans. He made himself popular in the capital of France by the decision and energy with which he carried out the imperial system of restriction of the press. He had gone to Ems for the benefit of his health, when he died suddenly as he was conversing with his colleague M. Magne, on the 7th of July, 1851. The decree for the suppression of him buried at the public expense, with the firing of guns, processions, and other honors, on the 12th of July, in the church of St. Thomas d'Acquin, Paris.

FOSSORES. [Hyemepstafa.]

FOSTER, JOHN, architect, was born about the year 1758 or 1757, and was the son of a builder of the same name, who carried on a large business in Liverpool where he also acted as architect and surveyor to the corporation, and as engineer to the docks. Foster junior was the second of six sons. According to one account furnished to us, he became a pupil of James Wyatt; and from other information it would seem that he was employed under Jeffry Wyatt, afterwards Sir Jeffry Wyatville. In 1800 he was associated with him at some time with Mr. Cockrell at Agina and Phigalaia; and was concerned in the excavation of the Aginian and Phigalian marbles. The portico at Agina—that of the temple of Jupiter was designed by him with favor, and in his latter practice as an architect. He did not return to England till 1816 or 1817, having in the meanwhile, at Smyrna, married a Greek lady of that place. However, about the time mentioned, he settled at Liverpool; and for some years afterwards carried on the building business, in partnership with a brother, under the firm of John Foster and Co.—his father having withdrawn, but retaining his professional appointments with the corporation and dock trustees. It does not appear that the numerous buildings in which Foster, senior, was concerned, were erected from his own designs; Foster, junior, however, had received better education in art; and for some time, besides his building trade, had considerable practice as an architect. St. John's Market, in Liverpool, a covered area of little short of two acres, and one of the earliest works of its character, was commenced in 1820, "from the designs of Mr. John Foster, the corporation-surveyor of the day, and was completed and opened for public use in 1826. The 'Architectural History of Liverpool' by Mr. J. A. Picton, read at the Liverpool Architectural Society; see 'The Builder,' vol. xii. p. 231.) It is probable however that such architectural design as there is in the work was due to the younger Foster, who with his brother was retained for the erection of the principal Liverpool public buildings. But Foster, senior, having been compelled by ill-health to resign his several appointments, Foster junior was appointed in February 1824 corporation architect and surveyor, receiving a salary of 1000l. per annum, conditional upon withdrawal from the building business. When the Municipal Reform Bill came into operation in June 1835, much of the influence of the Foster family was brought to an end, and John Foster retired with a compensation of 600l. per annum, and did not afterwards follow his profession.

Few architects have had opportunities similar to those of John Foster. It may however be questioned whether he succeeded in turning these to proper account. That he had acquired a thorough training cannot be doubted; but, like many of his contemporaries, he missed the special beauty of art in architecture in his manner of using the Greek models; and perhaps there is no town which now so well affords illustrations of two different systems of practice, as does Liverpool. We have said the works of Foster and the great work of Elns. [ELMS, HARVEY LONSDALE, S. 2.]

Amongst Foster's works is the church of St. Michael, Pitt-street, commenced in 1816, though not completed till 1822. It is a handsome, regular, portico, and steeply obviously adapted from the church of St. Martin's-in-the-Fields in the metropolis, but is by many considered his best work. The church for the School of the Blind first erected in Holborn-street, and since removed and re-erected in Highbury Park, is described as externally presenting a somewhat imposing effect in its Grecian Doric columns. This has been impaired by alterations in the removal. The

According to the census of 1831, the population of France was divided into—Roman Catholics, 34,931,023; Réformés, 260,067; Luthéria, 267,825; Jews, 73,995; other religions, 26,338. Of the rest the religion was unknown.

The population of France at the commencement of the 18th century was about 19,080,500, exclusive of Corsica and part of Lorraine, which were not then united to France. In the year 1763 the population had increased to 21,799,163, inclusive of Corsica and the whole of Lorraine. In 1784 it had further increased to 24,800,000.

The following table shows the different census returns of the present century, has been stated to be as follows:

<table>
<thead>
<tr>
<th>Year</th>

The naval forces of France amounted to 1,717,115,190 francs (about 65,686,000). The expenditure of 1,737,115,171 francs, the expenditure thus exceeding the income by 19,986,000 francs.

In 1856, the whole army of France amounted to 677,500 men, of whom 310,374 were in France, 64,325 in Africa, 197,597 not then returned from the Russian war in the East, and 3,007 in Italy.

In 1867, the total number of vessels comprising the fleet of France amounted to 353, of which there were 10 of 120 guns, 50 of 100 guns, 15 of 90 guns, 6 of 80 guns, 17 of 60 guns, 17 of 50 guns, 16 of 40 guns, etc.

The constitutional monarchy and representative government which had prevailed in France under King Louis Philippe, the head of the younger branch of the Bourbons, was abolished by the revolutionary revolution of 1848. A republic in form, governed by a president and a national assembly, these powers being elected by a suffrage all but universal, succeeded.

On December 3, 1851, Prince Louis Napoleon Bonaparte, President of the Republic, issued a decree dissolving the Legislative Assembly, establishing universal suffrage (the assembly had contested the right of the people to elect a president for ten years, and a second chamber, or senate. On the 20th and 21st of December, the French people, by 7,439,216 affirmative votes against 640,737 negative ones, adopted a provisional, or rather of the president, the constitution under which France has since been governed.

According to this proclamation the President, while he retained his title, assumed more than royal authority. He is responsible to the people alone who had elected him, and to a national assembly: he holds the command of the land and sea forces, the exclusive initiative in new laws, the right to declare the state of siege, among his leading attributes. A Senate was appointed, whose number was not to exceed 150, the members being named for life by the President, who may also grant them salaries. A lower chamber, called the Legislative Body, consists of 261 members, one for every 36,000 electors, and chosen for ten years by universal suffrage, but without the ballot. The sitting of both chambers is to be private, and official reports only of the proceedings of the Senate; the President may also prevent the publication of any member of the Senate, but not to the Legislative Body. The mayor of communes are appointed by the executive.

In this draft of the constitution the name of Republic was retained for the President. On December 3, 1855, in accordance with a decree of the Senate dated November 7, 1852, and a plebiscite carried by 7,389,665 votes against 204,401, the name of the government was changed, the old Empire was re-established, and Louis Napoleon Bonaparte was appointed Emperor under the name of Napoleon III, the throne being hereditary to his legitimate male descendants, failing which, the succession rests in Prince Jerome Napoleon Bonaparte and his direct legitimate descendants.
descendants in the male line by order of primogeniture. Since the establishment of the Empire some modifications have been made.

FRANKLIN, Rear-Admiral Sir John, was born in 1786 at Spilsby in Lincolnshire. His ancestors were subdivided into various branches of the family in different parts of the country, which though small was sufficient to give him local rank as a landlord. Unhappily, however, the property was so embarrassed that he was obliged to sell it, and he became entirely dependent on his commercial profits for the mainte-
nance of himself and his children. Besides the trade, he was besides the subject of this memoir, attained considerable rank and reputation. One, Sir Willingham Franklin, became judge at Madras; and another, Major James Franklin of the Bengal army, was highly distinguished for his scientific acquirements, which procured him the Fellowship of the Royal Society.

John, the youngest son, early evinced a great predilection for a sea-life. There is a story told of him which seems to rest on more than mere traditionary evidence. When a schoolboy at Louth in Lincolnshire, he availed himself of a holiday to go to the coast, a distance of twelve miles, in order to see the ocean, on which he gazed with wonder and delight for many hours. His father, who was extremely fond of him, and who had resolved that his son should follow any other profession than that of a sailor, conceived that by sending him in a small merchant ship to Lisbon, the discomforts of the voyage would effectually cure the lad of his love for the sea, but it had a totally different effect. Having accordingly, after a long period, he was sent on a naval profession, he was entered as midshipman on board the Polyphemus at the age of fourteen, and was in that ship in the celebrated battle of Copenhagen, from which he escaped without a wound, whilst a brother midshipman of the Kelly was killed.

He next joined the Investigator, under the command of Captain Flinders, his cousin by marriage, with whom he sailed on a voyage of discovery to the coasts of Australia. During this expedition, which combined investigations into natural history with geographical discovery, young Franklin had abundant opportunities—which were not neglected—of acquiring much valuable knowledge. Besides sound practical seamanship he learned the more theoretical and difficult branches of nautical surveying, and was always one of the midshipmen selected to attend the Captain whenever he made excursions in boats, or visited the shore for scientific purposes. After some time the Investigator being unfit for further service, the officers were ordered home in the Por-
poise. In this ship he was wrecked on a coral reef off the Australian coast, and with 94 persons spent nearly two months on a narrow sandbank only a few feet above the sea level, while Captain Flinders proceeded to Port Jackson for relief.

Having fortunately escaped the fate of his chief, who on his voyage home was unjustly detained as a prisoner in Mauritius, Franklin proceeded to Canton with Captain Forster, on board the Porpoise, and embarked on board the Earl Camden, in China, and in November 1801 arrived in London for the purpose of returning to England. This ship and other Indiamen were attacked by the French admiral, Linois, in the Straits of Malacca, but Sir Nathaniel Dance gallantly defeated his antagonist. During the engagement Franklin acted as signal midshipman, and was of considerable service in other ways.

Shortly after his arrival in England he was appointed to the ship Pallas of 96 guns, Captain Lieu, and had the charge on board that ship of the signals during the memorable battle of Trafalgar. It is recorded that he performed this important duty with singular coolness and intrepidity, although many of his brother officers were shot around him. Indeed, out of forty companions, only seven, of whom he was one, came out of the battle unscathed. He now served for two years in the Channel fleet and Rochfort squadron, and then joined the Bedford, in which ship he was present at the blockade of Flushing. The Pallas joined the Bedford, and on the attack of Newhaven in 1814 acted as the gun-boat officer, in the course of which he received a slight wound. For his gallant conduct on this occasion he was promoted to the rank of lieutenant.

In 1817 the Government was turned to Arctic discovery, which had been interrupted during the long war; and in 1816 commenced the brilliant and remarkable series of Arctic expeditions with which Franklin's name is so honourably associated. The scientific knowledge he had acquired when serving under Captain Flinders, was now of great benefit to him, and Sir Joseph Banks, who at that time presided over the Royal Society, and who took great interest in Arctic matters, re-
commended him to the Admiralty as a proper officer to be employed on that important duty. Accordingly Franklin commenced his Arctic career by commanding the Trent, which ship, with the Dorothea, commanded by Captain Buchan, formed an expedition appointed to sail from Spitze-
bergen across the supposed Polar University to the point at 80° 34' N. became disabled, but Lieutenant Franklin, with a gallant disregard of danger, earnestly requested to be allowed to proceed alone in the execution of the service. The nature of Captain Buchan's instructions prevented this, and the ships returned to England.

Franklin's conduct and aptitude for the peculiar service of Arctic enterprise brought him into prominent notice, and he was intrusted in 1818 with the command of his first over-
land expedition for the purpose of tracing the coast-line of the North American continent, at that time very imperfectly known. Descending the Coppermine River the party surveyed a large portion of the coast east of the mouth of that river, the line which was afterwards fished out of the journals and charts, and the chain of islands, which, though now complet-
ely unaffected, is undoubtedly one of the noblest pictures of heroic exertion and patient endurance ever presented for our admiration. The results of the labours of Franklin and his companion are such a monument of the memorable journey, deserve more full and fitting recognition than can be attempted on this occasion: the party travelled 5500 miles, mostly over ground previously unknown, and large acquisitions were gained for science by the careful study of the geology, physical geography and natural productions of the North American continent.

For his services on this occasion he was promoted to the rank of captain, having while absent risen from lieutenant to commander. In 1821 Franklin undertook the second and more important expedition of the Royal Society, and was intrusted on the council of that body. Undeterred by the appalling sufferings he had already undergone, Franklin, although lately united in marriage to the youngest daughter of William Forde, Esq., again voluntarily offered his services for Arctic exploration. These were accepted, and in 1825 he left England on his second land exploration. Descending the Mackenzie River, he traced the North American coast from the mouth of the Copper-
mine River to the 160th meridian. For these fresh services he was again promoted, and was elected Corresponding Member of the Institute of France.

Sir John Franklin now remained at home two years, when he was appointed to the Rainbow, and served in that ship in the Mediterranean for three years. He was chiefly employed in the Greek waters, and had the good fortune to be of con-
sequence in the delivery of the Strathaird to the Americans. His conduct was so satisfactory that he was made a consul, and was commended by Lord Glenelg as a man of sound judgment, his character being described as being a man of great integrity, and of unexemplary conduct. After a brief period of rest which followed his services in the Mediterranean, he applied to Lord Glenelg for employ-
ment under the Colonial department, and his lordship in a very complimentary manner offered him the important post of Governor of Van Diemen's Land, which he accepted, and held for seven years. During this time that colony received convicts, New South Wales having ceased to be a penal settlement. This rendered Sir John Franklin's position most onerous and difficult, and he felt none the less the importance of the situation of the colonists, that in grateful remembrance of his government, which was marked by the establishment of a college and a philosophical society, they, unsolicited, sub-
scribed 1000l. towards the expenses of a private expedition fitted out in 1834.

It might be supposed that, after so long a period of labours, the services, Sir John Franklin would have received still more recognition, particularly as he had now attained high age; but
but his wishes still pointed towards active employment, and consequently, when the Arctic expedition was contemplated, which had been promised him, he was placed in the new force under Sir John Franklin as second in command, when the Admiralty were of opinion that he was the officer best fitted to act as chief. That expedition was originated by the late Sir John Barrow, secretary to the Admiralty, who desired the commission for the north-west passage to government, which, after having been referred to the council of the Royal Society was adopted.

The expedition consisting of the Erebus and Terror, which had recently returned from a voyage of discovery in the antarctic seas, left England in May 1845. Unhappily its history and fate are still veiled in obscurity; however, we know, that everything was done to render it efficient, that the men under Sir John Franklin were men of experience and science, and the officers, chosen from them represent their commander animated by all the ardour and spirit which characterized his early arctic exertions.

It would have been unjust to have expected less from such a man, and as his instructions contained the usual discretionary power given in these documents, there is too much reason to fear that he fell a victim to his daring attempts to achieve success. It will ever be a matter of regret, though it will in all probability be only a shorter piece of history, that the Erebus and Terror at the entrance of Wellington Channel caused the search for our countrymen to be directed principally to the north and west of Barrow's Straits; because, although the information brought home by Dr. Rae in 1854, to the effect that he had seen a white man in the spring of 1850 on what is supposed to be Montreal Island, and, at the mouth of the Fish River, cannot be regarded as trustworthy; yet the relics of the expedition preserved by Mr. Anderson and Dr. Rae suffice to prove that Franklin's ships must have been beset within an area comprised within the 70th and 72d parallels of latitude and the 97th and 100th meridians.

Another expedition, and doubtless the last, has been sent out, however, if possible, to dissipate the mystery which still shrouds the fate of the Erebus and Terror, and their crews. The expedition left Aberdeen, July 1, 1857, in the Fox, a screw yacht, under the command of the distinguished arctic explorer, Captain M'Clinch doctrines. FRANZEN, FRANZ-MICHAEL, an eminent modern Swedish poet and prose-writer, was born on the 9th of February, 1772, at Uleaborg, in Finland, at that time a province of the Swedish crown. Finland, both before and since its composition, has been closely connected with Sweden, though possessed of a language of its own or an entirely different character. Runesberg, at present the head of Swedish poetical literature, is a Finn, and the first effort of Fränzen that attracted attention was his poetical eulogy on the fifteenth anniversary of the death of the poet and diplomat Fränzen, produced a commotion in the literary world of Stockholm, by the originality and vigour of its tone, which was in strong contrast to that of the school of Leopold, then dominant, who was an ingenious imitator of French models. The eulogy obtained, in spite of its originality, the great prize of the Swedish Academy. This was in 1794, at which time, and for nine years previous, Fränzen had been a student at the Finnish university of Abo. In the following year he set out on a tour to Denmark, Germany, France, and England, and became the pupil of Copenhagen, which destroyed a third part of the city. In Paris he ventured on a piece of composition in French verse, which was printed in a French periodical, and which he reprinted thirty years afterwards, who submitted a plan for the discovery of his country in the untried past. His work was chosen Bishop of Horsnand. Still while a resident in Finland, he had been chosen one of the eighteen of the Swedish Academy; a distinction of the same importance for a literary man in Sweden, as to be a member of the Royal Society in England. Fränzen held it one of his chief pleasures to have represented to him in its secretary, and remained so for ten years, during which it was part of his duty to write a series of biographical notices, which were much admired for their literary merits. He appears to have resigned the secretariaship on his elevation to the bishopric, which he held in 1847. Leign in his travels in Sweden gives an account of his meeting with Bishop Fränzen on board of a steam-boat, when going on a visit to his northern diocese, and speaks of the general affection and veneration with which he was regarded.

Archbishop Wallin, Bishop Tegnécr, and Bishop Fränzen were three of the most distinguished poets of Sweden in the present century. They were all three associated in the new Swedish version of the Psalms, a commission was appointed in 1814, and respecting the excellence of which there is but one voice, it being generally regarded as the best in Europe. It is singular that so little reference has been made to this fact, in the frequent discussions that have taken place on the expediency of obtaining a new poetical version of the Psalms in English. The poetical works of Fränzen were collected in five volumes, at Orebro in 1824 and subsequent years. The most successful are definitely the songs and the ceremonial poems, the songs being often sung both in Sweden and Finland. Their prevailing character is sweetness. The longer narrative poems, one of which, 'Sten Sture,' extends to twenty cantos and fills an octavo volume, are of a somewhat dry simplicity, both of style and incident, approaching to a kind of archaic poetry. The 'Finsk Romanist,' however, was regarded by Swedish writers as belonging to neither of the two rival schools of poetry in his time and country, the 'Academic' or Classical, and the 'Phosphorist' or Romantic, but as standing at a heads a third or neutral party. His poems, of which four volumes were published, are unusually animated; he was also the author of some controversial writings against the doctrines of the Rationalists, called forth by the controversy respecting Scharz's 'Leben Jesu.' The works of Fränzen, mentioned, have been collected under the title of 'Minnes-teckningar.' In the introductory speech before the Swedish Academy prefixed to them, the reader remarks a tone of courteous deference in speaking of Charles XIII., and even of the Russian government, to avoid living under which he left Finland, the absence of which would perhaps have inspired a higher notion of the dignity of Fränzen's character.

FRASERBURGH. [AEREBEBURGH, 11.]

FRATER. [FRAER, 11.]

FRINGILLA, a genus of Birds belonging to the order Fringillidae and the division Insectivora, the beak is straight, longer than deep, conic, and pointed; mandibles nearly equal, cutting edges entire, forming a straight comb; no feathers in the nostrils; no feathers in the frontal plumes. Wings with the first quill-feather longer than the fifth, but a little shorter than the second or third, which are equal, and the longest in the wing. Legs with the tarsi of moderate length; toes divided, and adapted for hopping and perching; claws curved and sharp.

F. colado, the Chaffinch. [CHAFFINC.]

F. montifringilla, the Mountain Finch, Brambling, or Bramble Finch. This bird is a visitor to this country only in winter, coming to us from the north, but at different times, according to the temperature of the country from which it emigrates. They have not been known to breed in any part of this country; those kept in confinement under the most favourable circumstances have not remained as long as one year. It is not an uncommon bird in Denmark. Mr. Hewitson saw them at one place in the southern part of Norway, where they were breeding. It is described as building in fir-trees; the nest formed of moss, and lined with wool and feathers; the eggs four or five in number, white, tinged with purple and spotted with dark red, like those of a chaffinch. The call-note of this bird is a single monotonous chirp.

FRUIT. In botanical language, that part of the plant which in the early stages of its growth is called the Pustil, and which bears the fruit. It depends on the species of the plant, when the ovules by the presence of the embryo, are changed into seeds. The Style and Stigma, when they still remain, retain their names, but the Germen is called the Pericarp, the Seed is the Embryo, which have no fruit, because they are not provided with a Germin; these therefore have Naked Seed-Buds, or Ovules,
and also naked Seeds (Semen nudis); such as Consine, Opiolaeae, and Lorantianae. But there are some plants in which the germin is easily destroyed, so that the seed-bud is developed without an envelope to the seed; these, in order to distinguish them from the former, are termed Semina decorticata or Fructus tectus, according as the germin only appears to exist, as in Lithum, or as this is surrounded by other floral parts, as in Anemone. In this case, the fruit is called a Simple Fruit (Fructus simplex), as in Nigella; or several, a compound or Multiple Fruit (Fructus multiplices), as in Ranunculus.

Pars, the parts of the Fruit are the Pericarp, the Spermophore, the Funiculus, and the Pulp.

The Pericarp is the transformed germin; sometimes it is united with the other persistent parts of the pistil, style, and stigma. The latter are seldom of particular importance; and all that need be said of them is that they are sometimes retained, as in Papaver, or they are more developed, as in Pulsatilla. The forms of the pericarp are exceedingly diversified, but admit of no general definition; they frequently exhibit hairs, prickles, protuberances, and membraneous spines, prominent or merely in pits in their intersepar. &c. The pericarp essentially determines the varied appearances of the fruit, by its diversity of structure. The parenchyma of the germin is developed in the Pericarp, in the mature pericarp only the epidermis of both surfaces, and between these a uniform layer of parenchyma, without vascular bundles, as in the lower Araeos, or traversed by a few simple bundles. In other cases only the epidermis of the outer surface is perceptible, and the latter is a true parenchyma, with the epidermis of the inner surface, is succulent or fleshy, as in Arora; or it may be, that under the epidermis of the outer surface some layers of cellular tissue are woody, while the underlying are fleshy; in both cases very frequently passing without determined boundary into the pulp.

In many other cases four layers are distinctly discernible, and have been named, counting from without inward, External Cellular tissue, Sarcocarp, the middle two undistinguished coats, the Endocarp. These various structures in the fruit are most important which cause the peculiar solutions of the continuity in the fully mature condition. Hence we obtain two comprehensive classes of fruits, according as their construction causes a separation into individual parts or not. The latter may be termed the berry-like, and the former the capsular. The capsular are again divided into two groups, according as the pericarp is united with the Spermophore, forming a compound berry-like, or the pericarp is separated into separate pieces, which do not again open, but firmly inclose the seed—Splitting Fruits (Sichincarpas), and their parts called Mericarpas. The Berry-like Fruits are also subdivided, according as the fruit, after leavelling, remains (1) the more tough and solid, and the outer more fleshy and juicy—Stone Berries (Drupe); or the reverse—True Berries (Bacca); or, lastly, all the layers appear thin and dry, or leathery (Achena). All these forms may, with the germin from which they arise, be united into superior or inferior, one or many celled, or one or many seeded; which only require to be noticed when deviations in the structure of the germin have arisen through abortion, being otherwise self-evident.

In the former there occur to the berry-like families. The mode of bursting (Dehisceo) is especially to be observed. The simplest process is an apparent wholly irregular tearing open at any place, as in Nicandra; usually however the form of the dehisce is very regular, even though it may be confused into a small part of the fruit, as in Papaver, Anthericum, &c.

The solution of continuity is either vertical or horizontal: in the latter case, the upper part forms a kind of cover upon the fruit—this is termed an operculum. In the first case, the pericarp, &c., falls away in more or fewer separate pieces, which are termed valves. In many-celled fruits the valves may separate entirely from the persistent septa, as in Coecas scabrosa (dehiscenta septifraga); or the septa may remain united, in the latter case, may form, or one of these lamellae on each of its margins (dehiscenta secpida, valvulae marginse septifera); or the septa may remain undivided, adherent to the middle of the valves (dehiscenta localisida, valvulae medio septifera). If in any of these kinds of dehisce a stalk-like mass of cellular tissue remains standing in the axis of the fruit, it is called the Columella.

From what has been said, it is sufficiently evident that these solutions of the continuity are not at all dependent upon the original composition. Such a relation has been assumed; and to the line in the external circumference of the pericarp, where the edges of real or pretended carpelles have been blended, the term (dorsal suture, has been applied by some botanists to designate this line; but it is more accurate to draw the line where the margins of one and the same carpel or similar part have become blended.

In the generality of caperful fruits, the above-mentioned folds or ripples in the pericarp remain distinguishable from the other; but they are usually very thin and membraneous or leathery, or more rarely woody.

f. The Schizocarp, or Splitting Fruits, are usually distinguished chiefly according to the direction in which the clinj occurs. This is either parallel with the axis of the fruit, or perpendicular to it, that is, the solution of continuity is either vertical or transverse. In both, the separate parts are usually only one-seeded. In the first case the separate parts are sometimes named Coeci or Mericarpas, in the last, Fruits Queriparces, or Segments. In this case, instead of the pericarp layers, the inner of which are always hard, and often woody; while the outer are fleshy or coriaceous: both are developed in a greater thickness than usual.

g. The True Berries, predominating in the families of Gramineae, Passifloraeae, Ocuveribaeae, and the Araeos, and occurring occasionally in many other families, consist essentially on the fleshy or juicy texture of the inner layers of the pericarp, which often exist to the exclusion of the outer coats; instead of the pericarp layers, the inner of which are always hard, and often woody; while the outer are fleshy or coriaceous; both are developed in a greater thickness than usual.

h. The Stone-Berries, characteristic of the Angyralae, but also presented in other families, owe their peculiarity to the pithy texture of the inner layers of the pericarp, and the outer being reduced to a dissolution into single cells, turgid with fluid, while the external layers are solid, and sometimes even woody, as in Lagenaria.

i. The Acanthias, with always thin dry layers, not usually distinguishable, characterise the families of the Gramineae, Cyperaceae, Osypulaeae, Compositae, and Diapodaceae, predominating in the Dryposites and Ranunculaceae, and occur simply in other cases. They are one-celled and one-seeded, generally with more than one seed-pace, as in Osypulaeae, through the abortion of cells and seed-buds.

With regard to the Spermophore it may be remarked, that in the dehisce of the fruit portions of cellular tissue are separated from the valves or septa, to which the seeds are united, in two principal ways—first, by the deaths of the sep- morphes. In these separations sometimes actually independent organs become dissolved from their union with others, as in Crucea, and sometimes merely pieces of independent organs become detached, as in Astrepodaceae.

The Pulp in the fruit assumes two conditions; on the one hand it passes into the loose cellular tissue of the pericarp in the true berries, as in Solanum; and on the other into the subsequent products of the funiculus; namely, into the aril of the fruit, as in Arum, and probably into the true aril, as in Rene.

The Funiculus exhibits manifold varieties, such as hairs, warty expansions among the seeds, membraneous, continuous, or lobed envelopes of the seed (arils), and so forth.

There are often parts external to the seeds, which are persistent till after the maturation of the seed (Sam), and they often undergo many changes; and when they become fleshy they assume the appearance of fruits. They are called perigonia, or the perianth. In the Flower of the Bean (Phase), seen in the case of the fruit of the Fig (Ficus), in which the peduncle or receptacle swells up and incloses the true fruits. The pedicel in Foeniculum dulcis also swells up and assumes the form of a fruit. In the Pine-Apples (Amarnae) the perianth is fleshy, and when the scale has been partly eaten. In the Mulberry (Morus) the perianth is the fleshy part; in the Bladder- Campion (Oiscabata baccifer) the calyx enlarges; in Mirabilis it is the corolla; and the hirs of the Rose (Rosa) are
the dilated disc, whilst in the Strawberry (Fragaria) the sweet juicy part is the receptacle.

The terms applied to the fruits of plants by botanists are very numerous. The same kind of fruit has frequently several names, whilst the same name has been applied to several different kinds of fruits. The following enumeration of some of these terms is given by Schleiden in his 'Principles of Science', whose remarks on this subject deserve careful attention from those interested in the further development of this subject.

Enumeration of the Various Forms of Fruit.

I. Seed naked (Semem nudum).

A. Seed solitary.

B. Fructifications.

II. Simple Fruits (Fructus simplex).

A. Capsule (Capsula).
   ⊖ Superior.
   5. Cupula circumscissa.
   7. Pyxidium, No. 5. One- or many-celled, formed of several carpels: many-seeded. Ex. Nyctalis.

   11. Silique. One-celled, or many-celled, one-valved, separating from the persistent stamens, forming a Septum (Reptum). Ex. Matthiola.

   15. Capsula. One-celled or many-celled, many-seeded, dehiscing by valves or pores, Primula, Anemone.
   ⊖ Inferior.

B. Splitting Fruits (Scissocarpos).

   19. Aechmenium. In Boraginaceae, Lamiaceae.

C. Stone Fruits (Drupa).

   21. Tryma, (imagined to be) one-celled by suppression in Juglandes.

D. Berry (Baccus).

E. Closed Fruit (Achumen).
   27. Aechmenium (Auctorium), Capsula (Lindley). One-celled, one-seeded, not blended with the seed. Ex. Compositae.

   29. Carpophytis. One-celled, one-seeded (imagined to be) blended with the seed. Ex. Brassicae.

III. Multiple Fruits (Fructus multiples).

A. Several Achmen.

B. Several Berries.

IV. Fructifications (Fructus compositi).

A. Capsula. With many-seeded fleshy pedicel.

B. Spikes with fleshy bracts and perianths.
   8. Spikes with wooly bracts and perianths.

V. Spurious Fruits (Fructus spurious).

40. Pomum. Many-seeded Achemen in one circle, blended with the fleshy disc. Ex. Malus.

41. Bacalosum. Many-seeded Achemen in two circles, blended with the fleshy disc. Ex. Passiflora.

42. Decleisio. Achemen enclosed in a hardened perianth or corolla. Ex. Spinacea, Mirabilla.

FRY, MRS. ELIZABETH, was the third daughter of John Gurney, Esq., of Earlham Hall, near Norwich, an opulent merchant and banker, and a member of the Society of Friends. Elizabeth Gurney was born May 21, 1780, at Bramerton, Norfolk, near Norwich, where she was brought up, and was a summer residence; in winter they occupied a large and commodious house in Norwich. They were not ‘plain Friends,’ that is, they did not wear the plain dress of the Quakers, nor use ‘thou’ and ‘thee’ in place of the ordinary ‘you,’ nor abstain from the usual amusements of social life. They of course attended the Friends’ meeting-house at Norwich, and the monthly and quarterly and yearly meetings; but in other respects there was little distinction between them and other persons who belong to the Church of England. Mrs. Gurney died when Elizabeth was only twelve years of age, leaving seven daughters and four sons. Mrs. Gurney’s business pursuits led her into intercourse with persons of all denominations; and a warm heart, social disposition, and courteous manners introduced him to many acquaintances without as well as within the pale of the Society of Friends. The daughters, as they advanced in years, especially the three eldest, dressed gaily, and sang and danced — sometimes attending concerts and balls at Norwich, and sometimes pursuing their favourite amusements at Earlham Hall, which had then become their father’s country residence.

Elizabeth Gurney, from the age of fourteen to seventeen, was, as she herself, ‘blessed with a somewhat sceptical, and her doubts greatly disturbed her. While she was in this flattering state of mind, William Savery, an American Quaker, paid a religious visit to England, and, on the 4th of February, 1796, preached in the Friends’ meeting-house at Norwich. His discourse produced a very strong effect upon her feelings, and turned the balance of her judgment in favor of religion — a change which subsequent discourses and conversations tended strongly to confirm. She had made great progress towards becoming a ‘plain Friend,’ and instructed about seventy poor children in her father’s house at Norwich, when Joseph Fry, who, with his brother, carried on an extensive business in London, paid a visit to Mr. Gurney at Earlham Hall. While there he made an offer of marriage to Elizabeth Gurney; and on the 19th of August 1800 they were married in the Friends’ meeting-house in Norwich. Joseph Fry and his family belonged to the strict section of the Quakers, and Elizabeth Fry was now prepared to adopt their ways. She resided with her husband in his house of business in Mildred’s-Court, in the City of London, till the spring of 1809, when, on the death of her husband’s father, she removed to Plashet House, Essex. In 1810 she became a preacher among the Friends, and ever afterwards continued to perform with great zeal the duties of her sacred office.

In the month of February 1813 she visited the prison of Newgate in London, and saw about 300 women tried and tried, with numerous children, crowded together, without classification or employment, in rags and dirt, with no bedding, and nothing but the floor to sleep on. The season
The antheridia are borne on branching jointed threads, called Paramenata, which rise, like the spores, from the walls of the conceptacle, and commonly fill the greater part of its cavity. Each antheridium is an oblong cell, forming the terminal articulation of the branches of the paramenata, and is filled with minute orange-coloured bodies called Sporidia (by J. Agardh), closely resembling the sporocores of the lower Algae, and each with two terminal movements. The motive organs are vibratory hairs, or cilia, with two of which each little body is furnished.

The Paramenata are easily known from all other Olivaceous Sea-Weeds, by a character at once natural, and easily ascertained, the spores within hollows sunk in the substance of the plant, and communicating with the surface by a pore. The order is represented in most climates, from high northern and southern latitudes to the equator. Very few species vegetate in the polar regions of either pole, in the Southern, in the Strait of Magellan, and in the Antartic Ocean the order is limited to Durvillaea and to Scolithus, and to Segetolitha, a fine Alga allied to sub-tropical forms. The British species, except masses, and the abundance is but a fourth; yet from the strictly social habits of several of them, they cover more surface of tidal rocks than all the other Algae put together. It is these plants which impart the deep brown colour to the rocks exposed on the coast.

The following is a synopsis of the British genera of these plants:

**Fucus.**—Brazilian bearing ribbed leaves. Air-vessels sinuses.

**Halidrys.**—Frond linear, pinnate, leafless. Air-vessels divided into several cells by transverse partitions.

**Cystoseira.**—Root scutate. Frond much branched, bushy.

Receptacles cellular.

**Fucus.**—Root scutate. Frond dichotomous. Receptacles filled with mucus, traversed by jointed threads.

**Himanthalia.**—Root scutate. Frond cup-shaped. Receptacles (frond-like) very long, strap-shaped, dichotomously branched.

1. **Sargassum.**—Frond furnished with distinct, stalked, nerve leaves, and simple axillary stalked air-vessels. Receptacles small, linear, tuberculated, mostly in axillary clusters or racemes. Seeds in distinct cells. The generic name is from Sargar, the Spanish term for masses of sea-weed found floating in the ocean in some latitudes.

2. **S. vulgaris.**

3. **S. boaeforum**, though both of them have been found cast on our shores, have no claim to a place in our British flora, being natives of the tropics, occasionally driven, with other tropical productions, by the force of the westerly currents on our Atlantic coasts. The species of this genus are found over a wide extent of ocean, and have been generally considered as tropical. They appear like floating meadows in the midst of the sea, sometimes probably support a larger number of living creatures than the most productive pasture in Great Britain. Myriads of Molluscs, Batoids, Fishes, and Crustacea may be seen playing about in these masses; and the abundance of Zoophytes which find shelter in such situations can hardly be estimated. The weed is eaten in China. In the East it is used as salads, and forms a pickle.

II. **Halidrys** has compressed linear fronds, pinnated with distinct branches. The air-vessels are lanceolate, stalked, divided into several cells by transverse partitions. The receptacles are entire, stalked, cellular, pierced by numerous pores, which communicate with immersed spherical conceptacles.

**H. silicicola** has linear very narrow branches, compressed linear lanceolate air-vessels, slightly constricted at the septa, prolonged upwards on rocks and stones in the sea, at and below half-tide level.

III. **Cystoseira** has a frond furnished with branch-like leaves, becoming more filiform upwards. The air-vessels are simple, arranged within the substance of the branch-like leaves consecutively. The receptacles are cylindrical, more or less lanceolate, tuberculated, and terminal. The seeds in distinct cells. The name is derived from two Greek words, signifying a little sack, and a chain.
C. ericoides has a thick woody short stem, cylindrical, and beset with numerous slender filiform branches, variously divided, and densely clothed with small spine-like awl-shaped ramuli (or leaves). It is found on rocks in the sea, and has the peculiar property of being able to exist under water in a growing state. In drying it becomes nearly black, and does not adhere to paper.

The other British species of the genus are—C. granulata, C. cozumelensis, and C. ambigua. The last is a species of rock-springs. It seems difficult to determine as to the duration of this plant. Some botanists consider it as annual, as the thongs are produced every year; but others say the long thongs are only receptacles, that the cup-shaped disc is perennial, and that this part is truly the plant. The thongs are often used in the nipa huts, and sewed to the rocks more than an inch in diameter. The branches or receptacles are in Scotland about six feet long. In Cornwall they are sometimes twenty feet long. The name in English signifies Sea-Thanoge. The fruit consists of tubercles immersed in the thongs, and these tubercles discharge their seeds by pores, which give the thongs a spotted appearance. This is remarkably the case when, after lying on the shore for some time, every pore is covered with a yellow dot, which is the nucleus of the plant discharged in the death-stegule which goes on, when, torn from the rock and tossed about by the waves, it lies withering in the open air. Dr. Neill mentions that in the north of Scotland a kind of sauce for fish or fowl, resembling ketchup, is made from the cup-like or fungus-like thongs of the plant.

P. tuberculatus is found in rock-pools, on the recess of the tide, near low-water mark. It is better known by the name of Puccus tuberculatus. It is very different in many respects from Puccus proper. When dry it becomes very brittle and black.

V. Fucus has a plane, compressed, or cylindrical frond, linear, dichotomous, coriaceus. The air-vessels, when present, areinate in the frond, simple and large. The receptacles terminal, cellular, pierced by numerous spores, which communicate with immersed spherical receptacles, containing the lower part of the receptacles parietal simple spores, and in the upper tufted anthelia. The name is from two Greek words, signifying [unreadable word].

P. tuberculatus is found in rock-pools, on the recess of the tide, near low-water mark. It is better known by the name of Puccus tuberculatus. It is very different in many respects from Puccus proper. When dry it becomes very brittle and black.

V. Fucus has a plane, compressed, or cylindrical frond, linear, dichotomous, coriaceus. The air-vessels, when present, areinate in the frond, simple and large. The receptacles terminal (except in Fuccus nodosus), turgid, containing the lower part of the receptacles parietal simple spores, and in the upper tufted anthelia. The name is from two Greek words, signifying [unreadable word].

VI. Himanthalia has coriaceous orbicular top-shaped fronds. Very long strap-shaped receptacles, repeatedly forked, springing from the centre of the frond, and traversed by jointed fibres, and pierced by numerous pores, which communicate with immersed spherical receptacles, containing either parietal spores or antheridia.

H. lorica is a rock-spring species. It seems difficult to determine as to the duration of this plant. Some botanists consider it as annual, as the thongs are produced every year; but others say the long thongs are only receptacles, that the cup-shaped disc is perennial, and that this part is truly the plant. The cup-shaped thongs which are produced are sometimes more than an inch in diameter. The branches or receptacles are in Scotland about six feet long. In Cornwall they are sometimes twenty feet long. The name in English signifies Sea-Thanoge. The fruit consists of tubercles immersed in the thongs, and these tubercles discharge their seeds by pores, which give the thongs a spotted appearance. This is remarkably the case when, after lying on the shore for some time, every pore is covered with a yellow dot, which is the nucleus of the plant discharged in the death-stegule which goes on, when, torn from the rock and tossed about by the waves, it lies withering in the open air. Dr. Neill mentions that in the north of Scotland a kind of sauce for fish or fowl, resembling ketchup, is made from the cup-like or fungus-like thongs of the plant.

FUCHSITE, a Green Mica from the Zillerthal, containing 8 per cent. of chromium. From the crystallization of mica two additions, specious hydroxy, from the old species so called. The common mica has an oblique prism for its primary. Many micas when in perfect crystals have the form of a hexagonal prism, but and one axis of perfect prismatic faces. This last face is straight while the second is bent at an angle to form a regular hexagonal prism. This species is properly distinguished, and has been called Hexagonal Mica.

FULLER, SARAH MARGARET, MARCHIONESS OSSOLI, was born at Cambridge-Port, Massachusetts, United States of North America, May 23, 1810. Her father was solicitor and a member of the Congress, perceiving her early aptitude, had her so highly educated that he was accustomed to speak of her while quite a child as knowing more Greek and Latin than half the professors, while she herself said that she had nearly forgotten her native tongue from constantly reading other languages. The consequence was, that when she grew to womanhood she had an overwrought nervous system, was a somnambulist, very near-sighted, and badly obstinate, yet through those defects an incisively dogmatic, and unquestionably well as cultivated person. The sudden death of her father in September 1835, threw upon her domestic duties and obligations to which she felt herself infinitely unequal.

She became a teacher at Boston of Latin, French, German, and Italian, then 'Lady Superior' of a school at Providence, Rhode Island, afterwards united herself for a while to that singular social or Fourieristic Society the 'Brook Farm Community,' and eventually took up her pen as a means of support. She had already become well known as a writer in the periodicals when she in 1839 published a translation of 'Eckermann's Conversations with Goethe.' Having acquired great celebrity in the literary circles of Boston, especially among the transcendentalists of that learned city, for her conversational talents as well as for her critical acumen, it was proposed to turn her powers that way to account, by forming under her guidance 'conversational classes' of the ladies of Boston. The scheme, odd as it may seem, met with acceptance. Five-and-twenty "of the most agreeable and intelligent women to be found in Boston and in its neighborhood" met at stated seasons to converse—the conversation being of course mainly on the side of the learned professions, and of the sciences, of the arts, of the heavens and earth; the will (Jupiter); the celestial inspiration of genius, perception, and transmission of diviné law (Apollo), and such other recondite themes as might be brought to the table, and which were conveyed upwards to the head of Psyche, and so forth; with poetry, music, the pictorial arts, the "thought that lies at the bottom of the different dances," and other more sublunary topics.

When Mr. Emerson storted his 'Dial' in 1840, Miss Fuller was one of the most prominent of his band of philosophers.
FUL 258 FUN

contributors; and she wrote for it many very clever articles on
the 'Fine Arts,' &c., some of which were subsequently repub-
lished as pamphlets. A biographical sketch of her, written as late as
1844, under the title of 'Summer on the Lakes,' an account of a summer tour. On the discontinuance of the
'Dial,' she removed to New York, and was installed direc-
tor of the literary department of the 'New York Tribune.' It
was not, however, for her literary or political views, nor for her
social philosophy; and she gave utterance to her impressions of
the wrongs of her sex in 'Woman in the Nineteenth Cen-
tury,' a work which excited some attention in England as
well as in America. She also published the collection of
romances and fables and her refuted the charges of
both of these works were, we believe, reprinted in London.
In the spring of 1846 she put in execution a cherished
scheme of a prolonged European tour. She first visited
England, where she stayed some time, and obtained in-
tructions to the study of the literary notabilities, whom she
describes and criticizes in her letters with a most amusing air
of superiority. In Paris she also remained for some time, and
formed the acquaintance of Madame Dudevant, &c. But Italy
was the place she had consented least to visit, and thither she
next proceeded—little dreaming to what a strange conclusion all
her theories of woman's rights and claims and missions
would there be brought.
For a brief space she revelled in the enjoyment of the scenery, the climate, and the boundless freedom which her region must bestow upon her; and that a portion of her time was occupied in rendering herself
conscious by her open and resolute, though somewhat im-
prudent avowal of extreme democratic opinions, and inter-
connected with persons obnoxious to the authorities on account of
the principles of the 'Dial.' In some of her letters she clearly,
involved herself in an affair of a very different though not less ex-
icating nature. She met by accident at Vespiers, in St. Peter's,
Rome, while separated from her friends by the crowd, a young
man of extraordinary beauty whose behavior with her charmed her;
an intimacy ensued, and, though he was many years her junior, so utterly uneducated that he had scarcely ever looked into a book, and without any kind of intellectual
pretensions, the strong-minded worshipper of intellect with a
very easy and gentlemanly manner, was in her hand. Ososi, though of a noble family, had a very small patrimony,
and that was in the hands of trustees. Moreover his family
were devoted Roman Catholics, and his elder brothers held
high appointments under the papal government; they would of
course be bitterly incensed at his marrying a lady not of
that faith, and especially one who was an avowed liberal.
He therefore urged that the marriage should be strictly con-
cealed; and to this she submitted. They were married on
December 27, 1846. This, when published in London, and
thought, as it seemed, to bear communications from him to
various Italian liberals; and she had converted her husband to
her own political creed. When the revolution broke out
her husband threw himself heartily into the movement; and
she shrank from none of the duties which her position and
her opinions seemed to have devolved upon her. During
the siege of Rome she was occupied as nurse, having charge of
one of the hospitals opened by the Roman Commission for
the succour of the wounded, and acted with a noble disregard
of toil or danger, and with much judgment as well as the
greatest kindness in her self-imposed task. The fall of the
republic compelled her to leave Rome; and with her hus-
bond and her child, she, after staying the winter at Florence,
embarked at Leghorn in May 1850, on board the Elizabeth,
for America. From the first the voyage was unpropitious;
the captain died soon after the ship sailed; the weather
was throughout stormy; and though the vessel reached the
Atlantic, she came only to be wrecked there, having
struck on Fire Island, Long Island, in the night of 16th, 1850.
A few of the passengers and crew were saved, but Margaret
Fuller, her husband, and child were among the drowned.
The body of her child came ashore, but her own tomb was
that.

The writings of Margaret Fuller will have no permanent
value in themselves, either for their literary merits, their
social opinions, or their estimates of character, of art, or
of literature. But they will retain a certain value, in connec-
tion with the history of their author, as illustrative of a
peculiar phase of society in America during the second
quarter of the 19th century. Margaret Fuller herself was
not a member of the great free thinkers, but she was able to
considerable attainments, but she had thoroughly studied a
single subject, and her writings are all disfigured by dogma-
ticism, assumption, and self-reference. In them you often
come upon a striking and apparently original thought; but if
you closely examine them, you will find yourself in the
position of studying a political pamphlet, disfigured, how-
soever its uncommonness mainly to peculiarity of expres-
sion: and sometimes these peculiarities degenerate into gen-
tericness. Had her life been spared however there can be
little doubt that what was strange, and almost repulsive in
her earlier manner, would have disappeared, and the better
and lovelier part of her character and intellect have revealed
itself. The severe mental discipline she had undergone in
Rome had, as she said in one or more of her letters, subdued
her pride; and with humility came in all the gentler virtues
and intellectual graces. Nothing could be more grateful
and beautiful than her conduct as a woman, a wife, and a mother
under her marriage trials, and during and after the siege of
Rome; and the letters which she wrote then are more graceful
and eloquent than perhaps anything else which has fallen
from her pen. She wrote an account of the Roman
revolution, the progress and suppression of which she had
watched so eagerly, but the manuscript perished with her.
(Memoirs of Margaret Fuller Ososi, compiled by her
friends J. F. Clarke, R. W. Emerson, and W. H. Channing,
FUNICAMIDE. (CHEMISTRY, S. B.)
FUNGI. There is frequently considerable difficulty in distin-
guishing Fungi from Algae, on account of Cryptothecium Plantas.
They are distinguished from Lichens by their more fugitive
nature, their more succulent texture, their want of a thallus
or expansion independent of the plant that bears the repre-
sentative spore; and sometimes the mycelium of one species
isogenous distinct from the fructifying bodies of a vegetative
germ so constant in Lichens.
From some forms of Alge they differ very little, but the
most obvious distinction is their mode of growth. The
Fungi grow by means of spores, while the Alges grow on the
bodies on which they grow, which is the case with all the
Fungi. There are however certain free forms of Fungi
which it is difficult to distinguish from Alge by this char-
acter; such are the moulds which are developed in list,
milk, and other liquids.
It has been stated that Fungi are distinguished from Alge
by the absence of spontaneous movement. It is no doubt
true that the condition of the protein which is the mobile
substance of the cell in Alge, is the same in Fungi. But this
Alge, but this is no general distinction. In those Fungi
which are developed in water, in one instance at least, the
Achlya prolifera, or Saprolegnia form, the movements of the
spores are as active as in any of the Alge.
There are several other facts which are important to the
conclusion that the cells of Fungi are actuated by means of
cells of a determinant figure, the whole centre of which consists
of spores attached, often four together, to the cellular tissue,
which at length dries up, leaving a dust-like mass inter-
mixed more or less with flocs, as in the puff-ball, or
sporidia, contained in membranous tubes or sacs, like the
Theom of Lichens, as in the Sphagnum. In their most
complete state they consist of two surfaces, one of which is
even and imperforate, like the cortical layer of Lichens;
the other separated into plates or cells, and called the
hymenium, to whose component cells, which form a stem
structure, are attached, the internal and external surfaces
formed by means of little processes, and generally in four, though
occasionally the number is either less or greater." (Lindley.)
The following is Schiedlein's account of the development of the
sporangia reproduction in the Fungi:
"The most simple (Hypogymnets, flamentous Fungi) form,
at the end of the thread-like cells, narrower pro-
portions, in each of which a spore is developed: this at
length separates, having consequently a double membrane,
the cell of the spore itself and the covering (vesiculums)
arising from the parent cell, as, for instance, in *Penicillusium* and *Botrytis*. In others the thread-like cells form a spherical swelling at the extremity, from which project a number of such prolongations, each of which contains a spore, while the others are divided spirally, as, for instance, in *Nucor* and *Penicillusium*.

In *Gasteromycetes*, the ventricular fungi the thread-like cells combine into pointed, or non-pointed, variously shaped sporocarps; in or upon which are spores, the spores being produced between the undulating edges of the spores, the thread-like cells often remain as tender as wool, and form, as in the *Trichioconis*, or as a delicate network (spilium), as, for instance, in *Stemonitis ovaria*, and the external capsule (uterus peridium) generally composed of the globules of the inner portion which burst in different regular ways, as in *Arceps* and *Geasterina*.

In the most highly developed Fungi (Hymenomycetes, membranaceous Fungi), elongated posch-like cells (probably only the ends of the interwoven film form fungus-cells, developed into the sporocarps, or cells formed at the ends of these cells) combine by arrangement side by side to form a membrane (hymenium). Some of the cells of this membrane may be enlarged considerably (sporangia), and send out from their tips thread-like extremities, in which of which a spore is developed. The film-like walls of the fungus, then either form round masses, closed in all round (sporocarp), with cavities in their interior, the walls of which are clothed by the hymenium, or they form definite spongy thalli or sponges, tubes in *Polyporus*, or lamellae in *Dolabella* and *Auricous*, which are clothed by the hymenium, as in the *Hymenomycetes*. Of the latter we only know, with any amount of accuracy, the law of development relating to the Todus-stools, and more especially that of the *Auricous*. In the latter it is observed that the spores appear between the excised mycelium, small hollow heads (volves), at the bottom of the cavity of which there grows a corpuscle, shortly pedunculated below, and enlarged into a spherical form at the top. In the lower part of this protuberance a horizontal circular opening is formed, the surface of which is attached the tubes, lamellae, &c. which bear the hymenium. The bottom of the cavity is only formed by a membrane (idium), which is either separated from the pedicel on its further development, or, leaving itself from it and the upper part at the same time, remains as a membranous ring (annulus) upon the stalk. The upper part, which supports the hymenium on its lower surface, dilates subsequently, and appears as an umbrella-like expansion, called the cap (patula), and when broken through the volva, which is very soon dissolved.

During their growth the same Fungi assume very different forms and appearances. It thus happens that the same species has not only been described under different specific names, but even in the same work of the same author. Fries states that he has traced no less than eight genera of different authors to mere degenerations or imperfect states of *Thelaphora* *sulphurea*. Nees von Esenbeck also states that the same species under certain conditions of cultivation as well as their differences the same species will produce Alge, Fungi, Lichens, or Mosses.

In the article *Entomptla*, S. 2, will be found an account of the plants growing on man and living animals. Many of these plants produce spores of a peculiar character, and maintain that according to different circumstances the same species will produce Alge, Fungi, Lichens, or Mosses.

The attacks of Parasitic Fungi cause extensive injury and disease in plants. Some very fat, and maintains that the spores of *Penicilliium* coming into contact with the plant act both as the predisposing and exciting cause of disease; others, perhaps more correctly, think that some change first is produced in the cells of the plant, which enables the spores to find a nidus, and to develop without injury to the plant. The blackened variety of *Nucor* always floats in the soil, and becomes a special type on account of the presence of the fungus: in the same way as vegetable organisms found in diseases of the skin are not to be looked upon as the origin of the disease, but as being developed in textures previously morbid, and as giving then a peculiar character to the disease. Many of the diseases of cultivated crops are attributed to Fungi. The spores of Fungi are very minute, and are constantly floating in the air. They can easily be applied to the surfaces of plants. When they find an appropriate soil they send out extensive filiform ramifications, which spread under the epidermis of plants, raise blisters, and finally burst forth in the form of orange, brown, and black spots, constituting the fruit. The specific constitution of the spores is the same in the stalk, the spore, and the fruit. Different species are restricted to different plants, and even to different parts of the same plant. The forms which the same fungus assumes seem to vary sometimes according to the kind of host which it grows. The disease called Blue, Smut-Bole, or Pepper-Bole, is occasioned by a culture *Uredo carvis* by De Candolle, and *Uredo festata* by Bauer. It attacks the grains of wheat, and may be detected in them in their earliest state. It consists of extremely minute globules of black, which burst, the spores being scattered in different regular ways, as in *Arceps* and *Geasterina*.

It is the most highly developed Fungi (Hymenomycetes, membranaceous Fungi), that penetrate the sporocarps, or cells formed at the ends of these cells; (probably only the tips of the interwoven film form fungus-cells, developed into the sporocarps, or cells formed at the ends of these cells) combine by arrangement side by side to form a membrane (hymenium). Some of the cells of this membrane may be enlarged considerably (sporangia), and send out from their tips thread-like extremities, in which of which a spore is developed. The film-like walls of the fungus, then either form round masses, closed in all round (sporocarp), with cavities in their interior, the walls of which are clothed by the hymenium, or they form definite spongy thalli or sponges, tubes in *Polyporus*, or lamellae in *Dolabella* and *Auricous*, which are clothed by the hymenium, as in the *Hymenomycetes*. Of the latter we only know, with any amount of accuracy, the law of development relating to the Todus-stools, and more especially that of the *Auricous*. In the latter it is observed that the spores appear between the excised mycelium, small hollow heads (volves), at the bottom of the cavity of which there grows a corpuscle, shortly pedunculated below, and enlarged into a spherical form at the top. In the lower part of this protuberance a horizontal circular opening is formed, the surface of which is attached the tubes, lamellae, &c. which bear the hymenium. The bottom of the cavity is only formed by a membrane (idium), which is either separated from the pedicel on its further development, or, leaving itself from it and the upper part at the same time, remains as a membranous ring (annulus) upon the stalk. The upper part, which supports the hymenium on its lower surface, dilates subsequently, and appears as an umbrella-like expansion, called the cap (patula), and when broken through the volva, which is very soon dissolved.

During their growth the same Fungi assume very different forms and appearances. It thus happens that the same species has not only been described under different specific names, but even in the same work of the same author. Fries states that he has traced no less than eight genera of different authors to mere degenerations or imperfect states of *Thelaphora sulphurea*. Nees von Esenbeck also states that the same species under certain conditions of cultivation as well as their differences the same species will produce Alge, Fungi, Lichens, or Mosses.

In the article *Entomptla*, S. 2, will be found an account of the plants growing on man and living animals. Many of these plants produce spores of a peculiar character, and maintain that according to different circumstances the same species will produce Alge, Fungi, Lichens, or Mosses.

The attacks of Parasitic Fungi cause extensive injury and disease in plants. Some very fat, and maintains that the spores of *Penicilliium* coming into contact with the plant act both as the predisposing and exciting cause of disease; others, perhaps more correctly, think that some change first is produced in the cells of the plant, which enables the spores to find a nidus, and to develop without injury to the plant. The blackened variety of *Nucor* always floats in the soil, and becomes a special type on account of the presence of the fungus: in the same way as vegetable organisms found in diseases of the skin are not to be looked upon as the origin of the disease, but as being developed in textures previously morbid, and as giving then a peculiar character to the disease. Many of the diseases of cultivated crops are attributed to Fungi. The spores of Fungi are very minute, and are constantly floating in the air. They can easily be applied to the surfaces of plants. When they find an appropriate soil they send out extensive filiform ramifications, which spread under the epidermis of plants, raise blisters, and finally burst forth in the form of orange, brown, and black spots, constituting the fruit. Different species are restricted to different plants, and even to different parts of the same plant. The forms which the same fungus assumes seem to vary sometimes according to the kind of host which it grows. The disease called Blue, Smut-Bole, or Pepper-Bole, is occasioned by a culture *Uredo carvis* by De Candolle, and *Uredo festata* by Bauer. It attacks the grains of wheat, and may be detected in them in their earliest state. It consists of extremely minute globules of black, which burst, the spores being scattered in different regular ways, as in *Arceps* and *Geasterina*.
wheat many of the infected grains are crushed, and the spores are dispersed in the form of fine powder which adheres obstinately to the sound grain, by means of an oily or sticky exudation from the flour. When wheat is dried thoroughly, it has been considered useful to add some alkaline ley to the water in which they are washed. The alkali unites with the oil and forms a soapy matter. Lime has been used, but for the same reason as described above, containing ammonia, and the liquid from stable dung have also been employed; other matters, as sulphate of copper, act by destroying the vegetating powers of the Fungi.

Mr. Ellis, of Barning, Kent, says that the invariable practice of storing wheat in blackest wheat in boiling water, and afterwards drying it with lime. The wheat placed in a colander or in a basket is immersed in boiling water for a few seconds, just long enough to wet it completely, it is then immediately dipped in cold water and immersed in the warm water, mixed with other wheat, and sown. By this means the wheat was always found to be cured of smut, while the vegetating principle was uninjured, great care being taken that the water was boiling, and the wheat taken out of the water as soon as properly wetted. Mr. Ellis tried an experiment on a bushel of the blackest wheat he could procure, which he divided into sixteen equal parts, sowing them all the same day, but with different treatment. The result at harvest was that the wheat which was exposed to the influence of the black eye, and killed off, of every 100, while that dipped in boiling water and limed had not a black ear in several thousands which were examined. Many other species of Uredo as well as Ustilago grains, the spores of which are disseminated in the field, receive their names from the plants on which they parasitize, or from the situation in which it grows. Ustilago Maydis, a maize smut, is a fungus which gives rise to protuberances on different parts of the maize. The stem, upper leaves, and especially the bracts become immensely swollen when attacked by this disease, and the ovaries, ovules, and male blossoms are not exempt. The part affected are at first white tinged with red, smooth and juicy. The cellular tissue increases in size, is devoured by the spores, and is succeeded by rae mycelium and spores. The spores are twice as large in linear measure as those of the oat smut. At first the small balls contain a dark strong-smelling fluid, but ultimately the masses become dry, and present a multitude of dark dust mixed with irregular threads. Ustilago vittata causes disease in grasses in India. The spores are black and round, and the disease they occasion is denominated Graminis, or Black-river disease. In France, according to Leveille, the immense quantity of black dust resulting from it in the hay-fields of France, produces injurious effects on the haymakers. A species of Deppezia or Septoria sometimes occurs in the grains in the knots of wheat. Various species of Erysiphe, such as E. hordei, E. graminis, E. aduncus, and E. bicolor give rise to kinds of mildew. Erysiphe are often met with in common pea crops. Some say that Oidiurns are merely particular states of Erysiphe. The plant producing mildew in the vine is the Oidium Tuckeri of Berkeley. Other species of Oidium probably cause mildew in the peach, rose, hop, pea, and onion. For destroying the mildew in vines sulphur is recommended to be dusted on them. Some also use a solution of hydro-sulphate of lime, made by boiling sulphur and lime in water. A fungus called Rhizostoma Malti is said to grow on the roots of apples, pears, and quinces, and to cause destruction to the trees. Ergot is a monstrous state of the grain, in which the entire diseased ovary protrudes in a curved form resembling a cock's sparrow, hence the name from the French 'erget,' meaning a spur. The ovary is black externally, spogy internally, and contains much oily matter. Some consider it as produced by the attack of a fungus, which destroys the ovary, and replaces it by a large ovarian sack. The disease is usually met with in rye, and the name of spurred rye is applied to it. It sometimes occurs in wheat and in barley, and it has also been noticed in Lolium perenne, Lamium album, Arabis, Atriplex, Triticum, Dactylis glomerata, Anthoxanthum, Pulsatilla arundinacea, and Alpecoeca agrestis. Ergot consists of a very dense tissue formed by polygonal cells, united intimately with one another, and filled with an oily fluid. It is discovered in the uninregnated ovule of rye, for although extremely diluted by the stamens and rendered deficient of recognition, the integuments of the ovule increase without completely losing the form which they would have assumed, if they had grown into a true grain, imitating in this respect the ovary of an egg, which fertilization has replaced the seed. The solid mass which has been called Sclerotium clavus by Deppezi, and the filamentous portion called Sphaecelca by Leveille and Feé, and Erypsios spicant, is only, properly speaking, organs of vegetation. The fungus destined to grow from this apparatus is an elegant Sphaeria, probably that called by Fries Cordyceps purpurea. This plant has been seen by Schumacher in diseased cereals, and it has been detected by Boussell in Sclerotin in Blattis, in which the Sphaeria is the casey camalgamos, and by Dumeril in Ergot of Rye. Tulasne has shown that this Cordyceps is produced from the Ergot when it is allowed to vegetate. Ergot of Grasses and Ergot of Cupressaceae, according to Tulasne, do not belong to the same vegetable species. Rye affected with this disease, when used as bread, is very prejudicial. The Abbé Tesser showed that Ergot caused gangrene in animals that fed on it, and many instances are recorded of gangrene of the extremities occurring in persons who had lived on diseased rye. Ergot is said to prevail in rye grown on wet and stony land.

The disease which has recently attacked the Potato in various parts of the world is by many attributed to the attack of a species of black eye, but by Berkeley, who describes the fungus as Botrytis infestans. The spores are supposed to enter the stomata and to cause disease in the leaves in the first instance, which afterwards extends to the tubers. The effects produced on the leaves resemble those produced by certain poisonous gasses, such as hydrochloric, sulphuric, and nitric acids. Berkeley attributes the Potato disease entirely to Fungi. He states that the disease commenced in the leaves. They were attacked by the mould, which ran its course in a few hours; and from the rapidity of the action, the period for examination of the leaves has often passed over. The fungus generated does not live on decayed or decaying matter, but is one which produces decay, and renders the plants unsafe for use. The compact mass of mycelium prevents the elaboration of the spores in the leaves, obstructing the admission of air and the emission of transpired fluids. The stem is thus overcharged with moisture, and ultimately rots, while every source of nutriment is cut off from the half-rotten tubers. The atmospheric changes during the late disease made the fungus spread rapidly.

While there is no doubt that the Botrytis is developed in the progress of the Potato disease, the question arises whether the decomposing mixture is not produced or produced by a Fungus which is itself most consonant with the phenomena is, that changes are induced in the cells of the potato by cultivation which render the leaves liable to disease. Atmospheric influences are thus enabled to act upon them, so as to cause ailments in which the appearance of the disease is assumed as the Botrytis, accelerates the morbid action, and causes it to assume a peculiar form. In this way high cultivation, atmospheric influences, and Fungi, all contribute to cause disease. In the Potato disease of 1868, Haring says that brown granular matter was deposited in the cells, first in those near the epidermis, then the cellular walls lost their transparency, and the cells could no longer be isolated by boiling water; next the cell-wall was destroyed, and small cavities were formed in the midst of the tissue, in which were agglomerated grains of starch, and finally parasitic organisms appeared in the cavities. The vegetable parasite developed were Polyza obs, Fumiporos Solani, F. difformis, F. caudinum, and Oidium violaceum. When the disease had advanced in the tubers, the spores were present in the digestive passages. The vegetable parasites were present in the tissue, in which they formed the starch, which is the food of the fungus of the potato disease. He says that decaying organic matter is necessary for the growth of Fungi. He thinks that the disease is caused by the presence of putrefying animal matter in the stem, just below the surface of the soil; this admits the fungus to enter, after an inadmissible struggle between vital and chemical forces, and induces decomposition by a process of fermentation. The azotised matter, in a condition to act as ferment, is produced by the state of the season, by deficiency of light, and by other meteorological causes. Analyses show that the constituents of the diseased
potato undergo a rapid and important change. Dr. Lyon Playfair and Mr. Phillips found that the amount of albumen and gluten decreased from 9.34 in the sound potato to 0.2 in the diseased one; and when the disease advanced they finally disappeared.

"Mitscherlich says that the change which cellulose undergoes by the action of a peculiar ferment is characteristic of the potato; that if a half putrid potato cut up into pieces is placed in water with portions of fresh potatoes, and allowed to stand till the cells of the fresh portions begin to be easily separable. It is also formed, though more slowly, when fresh potatoes cut up into slices are placed in water; the fresh and fresh potatoes, cut in slices, added to it; when these are decomposed, a portion of the liquid may be treated with water, and more slices of potato added, which soon become decomposed, and in this manner increase the activity of the liquid. Hence, just as the fermentation of an infusion of malt, the yeast, the fermentative fungus, becomes augmented, so does the ferment increase. It only acts upon the cellulose, which forms the walls of the starch-cells of the potato; first the cells separate from each other, so that it furnishes us with a convenient means of obtaining the cells with their contents in an isolated state, and facilitating their examination; the walls of the cells are subsequently also dissolved, and the starch-particles fall out: in this manner, in 24 hours, a solution is obtained, which shows that this portion can be removed by a force of forceps, the hard mass of the potato lying beneath the softened layer, so that this process takes place successively from the outside towards the inside, the outer portion being simultaneously permeated by the ferment to the innermost portion. Exactly the same process as that which we can produce spontaneously, he says, occurs in the potato disease, which during late years has done so much mischief. In this also the cellulose, so to speak, is not the starch, is decomposed; and the liquid, which the author had kept for a long time in contact with one of the diseased potatoes, immediately produced the decomposition of a sound one. This decomposition is, therefore, he says, not the disease itself, but merely one of the symptoms, which is produced by the dying or the previous death of the entire plant, and just as it is well known in the case of other plants that they die when the spores of their roots are too strongly cooled, so may a sudden cold rain following a long warm winter produce a similar condition of the potato plant. It is only after decay has commenced that Fungi and insects attack the plant.

"Liebig attributed the Potato disease to diminished or suppressed transpiration, depending upon the hygroscopic state of the roots, which is occasioned by the precipitating of the moisture in regard to the Hop blight, in which the disease is traced to the want of correspondence between absorption and transpiration, and a consequent stagnation and decomposition of the juices. The same thing, he thinks, takes place in potatoes, where the leaves are suddenly covered with moisture; and he shows that in 1845 and 1846, when the disease overran Europe, damp, cold, and rainy weather followed heat and drought just at the period of the most luxuriant growth of the potatoes. The vessels and cells became charged with fluids; and, owing to the checked transpiration, there was stagnation of the sap and death.

"Fungi and putrefaction are, according to him, the consequences of the death of the plant. Klootsch proposes to check the Potato disease by pinching off the extremes points of the branches and twigs to the extent of half an inch downwards when the plants have attained the height of six or nine inches above the soil, and to repeat this on every branch two or three times, so that it shall be as if the plant were cut to the stem and branches, he thinks, will direct the nutrient matters in the direction of the increase and multiplication of subterranean as well as aerial branches. This leads to increased development of tuber, and strengthens the leaf and stalks. Professor Lamb of Oxford, on the contrary, has saved potatoes from disease by cutting off the stems after flowering with a very sharp knife, and then covering the ground with earth to the depth of not less than an inch and a half. The top dressing thus applied was not disturbed till the flowers had faded, in order that the young tubers might not be cut. It is said that the tubers acquired a good size and were of excellent quality. If these facts are true, it would appear that, while leaves are necessary to the development of tubers, the latter on acquiring a certain size can continue their growth by their own proper and unassisted vitality. The general conclusions to be drawn from all that has been said relative to the Potato disease are, that changes are induced in the cells and vessels of the potato by certain humid or dry atmosphere, in which the decomposition takes place in the cellulose and in the contents of the cells, which speedily leads to decay; that parasitic Fungi find a nidus in the decaying organic matter, so as to enable them more readily to infect the disease; and that, as yet, no remedy has been devised.

For an account of the Fungi supposed to produce Dry-rot in timber see the article Dry-Rot.

In many parts of the world the Fungi afford a supply of food to the inhabitants. Among them are not more than half a dozen species are to be found in the markets of London, and only the common Mushroom, Truffle, and Morel are eaten in Paris; in Italy and other parts of Europe, a large number of species are consumed. [Astraeus.] Dr. Rude in his book on "Excellen Funguses of England," gives descriptions and drawings of the following species of British Fungi as those which may be used as food:—

The other species of Fungi that have sometimes been employed in medicine, are mentioned in a previous article. A fungus which is used in the South of France is called the Acrepus peronatus, A species sold in Covent Garden under the name of Brieuets, and which writers agree in regarding as perfectly free from danger.

The poisonous principles produced in the Fungi have sometimes been employed in medicine, an instance of which is given above in the Ergot. The action of a species of Bovista has been found similar to that of chloroform. [Bovista, S. 1.] The Amanita muscaria possesses an inebriating property, which is employed in the manufacture of an inebriant. The following is the account of Landegord, as given by Dr. Greville:—

"This variety of Amanita muscaria is used by the inhabitants of the north-eastern parts of Asia in the same manner as our opium, namely, in the form of tinctures and preparations. Such Fungi are found most plentifully about Wissana, Kamtchatka, and Willowa Derecos, and are very abundant in some seasons and scarce in others. They are collected in the hottest months, and hung up by a string to dry in the air; some dry of themselves on the ground, and are said to be far more narcotic than those artificially preserved. Small deep-coloured specimens thickly covered with warts are also said to be more powerful than those of a larger size and paler colours. The usual mode of preparing the fungus is to roll it up like a bolus and swallow it without chewing, which the Kamtchatkadens say would disorder the stomach. It is sometimes eaten fresh in soups and other cookeries, and then loses much of its intoxicating property.

When steeped in the juice of the berries of Vaccinium uliginosum its effects are those of a strong wine. One large or two small Fungi are a common dose to produce a pleasant intoxication for a whole day, particularly if water be drunk after it, which augments the intoxicating property. The desired effect comes on from one to two hours after taking the fungus. Giddiness and drunkenness result in the same manner as from wine or spirits: cheerful emotions of the mind are first produced, the countenance becomes flushed, in a word, the digestive system is at last an entire loss of consciousness. It renders some remarkably active, and proves highly stimulating to muscular exertion. By too large a dose violent spasmodic effects are produced. So very exciting to the nervous system in many individuals is this fungus that the effects are often very
ludicrous. If a person under its influence wishes to step over a straw or a small stick, he takes a stride or a jump summary, and this is the result of the plant's habit cannot keep silence or secrets, and one fond of music is perpetually singing. The most singular effect of the Amianthus is the influence it possesses over the urine. It is said that from time immemorial the inhabitants have known that the flower imparts an interesting quality to that secretion, which continues for a considerable time after taking it. For instance, a man moderately intoxicated to-day will by the next morning have slept himself sober, but (as is the custom) the smell of his urine will be more powerfully intoxicated than it was the preceding day. It is therefore not uncommon for confirmed drunkards to preserve their urine as a precious liquor against a scarcity of the fungus. The intoxicating property of the urine is carried with it, being forced upwards, so that the partials of it, has its urine similarly affected. Thus, with a very few Amianthus a party of drunkards may keep up their debauch for a week.

Dr. Langdorff mentions that, by means of the second person taking the urine of the first, the third of the second, and so on, the intoxication may be propagated through five individuals.

Fungi are often phosphorescent. The light given out by species of Rhizomorpha in the coal-mines of Dresden is described as the appearance of an enchanted castle. An agaricus gardineri, which grows on the palm of Brazil, is a considerable. The same phenomenon has been observed in A. olivarius in the south of Europe, and in two species of Fungi at Swan River. Dr. Hooker describes plates of these fungi growing upon decaying wood in the forests of the Sikkim Himalaya.

It is generally stated that Fungi differ from the rest of the vegetable kingdom, in the absorption of oxygen and the discharge of carbonic acid gas. In experiments which have been performed, this has been the result; but it is well known that the tissues of Fungi are easily decomposable, and it is more probable that the absorption of oxygen, and the giving out of carbonic acid gas is the result of decay, rather than the cause of the growth of the plant. The following substances were found by Fungi: 1. Water; 2. Cellulose; 3. Nitrogenous Substances; 4. Fatty Matters; 5. Sugar; 6. Volatile Matter; 7. Sulphur; 8. Salt; containing Siles and Potash. These substances are analogous to the ordinary products of the decomposition of water, ammonia, and carbonic acid gas by oxidation, and must either be formed by that process in the fungus itself, or taken directly up from the substances on which they grow, by absorption.

A curious fact with the development of Fungi is the occurrence of vegetable cells, referred to this order, in liquids undergoing fermentation. During the conversion of malt into beer, plant-cells are constantly observed to be present in these bodies, described as a plant, under the name of Saccharomycete Cells. During the preparation of the containing of, as now carried on at Belfast, Professor Allman has observed present cells resembling those of Saccharomycete. Whether these are true plant-cells or not, they is still a question; and it is still more a question as to whether they have anything to do with the changes going on in the solutions in which they occur. They are probably a result, and not the cause, of fermentation. These cells have not escaped the observation of Schleiden, and the following is his account of them:

"In the last place, I must mention a highly interesting analogy, which, when more accurately examined, may perhaps one day lead to the most satisfactory explanation of the process of vegetative reproduction of—I mean viscous fermentation. We have here a fluid in which the constituents are, turbinin, and inorganic matter, as a yeast, are present. At a certain temperature, which is perhaps necessary to the chemical activity of the nucleus, there originates, without, as it appears, the influence of a true cell-forming power (the origin of the so-called fermentation-fungus), and it appears that it is only the vegetation of these cells which produces the peculiar changes that occur in the fluid. Which, in its opinion, is really a fungus, is a matter of indifference; but whether it is alone, through the activity of its vital processes, determines the process of fermentation, deserves to be accurately determined.

"I will here add my own observations on these fermentations. I bruised some currants with sugar, and having pressed the juice through a cloth diluted it with water and filtered through folded paper. The fluid was bright red, quite clear and transparent, and, under the microscope, showed a few large drops of a pure clear oil. At the end of twenty-four hours the whole fluid was opalescent, and presented, under the microscope, a number of granules suspended in it. On the second day these granules had greatly increased, and there appeared amongst them perfectly-formed ferment-cells. There also appeared, now and then, vesicles of carbonic acid gas. On the fourth day fermentation was very active. At the bottom of the vessel and on the surface of the fluid, yeast cells were seen, and a single yeast spot; but whether hollow, or a solid nucleus, I could not decide. The remaining parts appeared entirely homogeneous, yellowish or a nitrous substance, sometimes mixed with small solid granules. In a similar way, a solution of sugar with elder-flowers was examined, and the similar results. Other results were obtained in the following way:—Pure white protein (albumen) from the white of an egg, was dried, and rubbed down with sugar, and left to ferment: the fluid at first was perfectly clear. On the third day, the small porcine granules of yeast, were formed, and whilst the sharply angular aspect, assumed partly a granular aspect, and some a more or less rounded form. These glories showed an active molecular movement, and some appeared strongly stained with violet. After the third day, no yeast cells were formed, but a few granules round or elongated cells, which were either solitary, or arranged together in a line with a tendency to the formation of branched fibres. These cells were not more than one-third of the diameter of ordinary ferment-cells. An active fermentation was produced, and the fluid given out from the protein-granules and the linear cells. Proper ferment-cells did not make their appearance. Fluid albumen, mixed with sugar, and filtered, became thickened on the second day, and contained little granules of albumen, resembling those exhibited by the preceding, except that there were developed a few true ferment-cells. Protein moistened with water displayed the same appearances as when mixed with sugar and water; ultimately putrefaction came on, and the development of Infusoria, but the vegetable formation preceded. There appears to be two very different types of ferment-cells, according as the fluid contains organic acids and essential oils, or not. From the phenomena exhibited by the ferment-cells, it is naturally supposed that they may be referred to regard them as ordinary cells, which are formed through a cavity in the cytoplasm, and which afford indications of the nuclei in their highest development. But this analogy is not tenable, and the above observations must be regarded as imperfect. If we take the ferment-cells, and consider them as formed of alcohol, or caustic alkalies, there will be found in the fluid a number of globular delicate cells, with thin but clearly distinguishable walls, which contain a clear fluid, with here and there very small granules, which, alone or in groups, are attached to the inner surface of the cell-wall, and (almost) always a large round flat body (a cytoplasm)."

The following arrangement of the Fungi is given in Lindley's 'Vegetable Kingdom'.

Hymenomycetes, or Agaricae.
Gasteromycetes, or Lycoperdaceae.
Conylomycetes, or Ustilaginales.
Hyphomycetes, or Myceliales.
Sporidia, or Sporocarps.
Bolbitophyceae, or Phycomycetes.
Phycomycetes, or Bryophyta.
Opisthogonata, or Tracheophtyllum.

Fusel oil. (Chemistry, & c.)
When the German parliament was assembled at Frankfort for the purpose of forming a confederation of the smaller states under a central government, Heinrich von Gagern (son of the above Baron) was appointed president, May 19, 1848; and on the 30th of June, when his first term of office expired, he was re-elected. On the 18th of December he resigned the presidency of the assembly, and Eduard Hamon of Koblenz was chosen his successor; but in March, 1849, Baron von Gagern being nominated by the Regent of the Empire to the offices of Minister of Foreign Affairs and President of the Council of Ministers. After many discussions it was decided that, as the military constitution of Bavaria constituted an Empire, and that the imperial dignity should be offered to the King of Prussia. The offer was accordingly made, and negotiations between the parliament and the king continued for some time; but the king ultimately refused to accept the compromise proposed, and the assembly was dissolved without producing any result.

GALBA [Balestrini].
GALE, SWEET. [Myrosa, S. L.]
Galeocerdo. [Sepalidae.]
Galeus. [Squalidae.]
Gallaudet, Rev. Thomas Hopkins, to whom America is indebted for the introduction of instruction for the deaf and dumb in this country. December 10, 1877.
Hanging passed through Yale College, on the 17th of March, 1833, to prevent the study of the law; but being forced to abandon it, in consequence of ill-health, he engaged for a while in commercial pursuits; then, in 1814, he entered the theological seminary at Andover, and, being licensed to preach, was chosen pastor of a congregational church at Portsmouth, New Hampshire. While thus occupied he became much interested in a little deaf and dumb girl, Alice Cogswell, the daughter of a friend, and he was induced to attempt to instruct her. In this he was by great patience very successful, and his father, Dr. Cogswell of Hartford, was incited by the great benefit which his child had derived, to earnest efforts to extend the blessings of education to other children suffering under similar deprivation. An association was formed, and funds being provided, a requisition was made to Mr. Gallaudet to resign his ministry, and proceed to Europe for the purpose of learning the system and organisation of the existing deaf and dumb institutions.

After some hesitation, caused by a reluctance to separate from his flock, he accepted the offer; and in May 1816 embarked on his mission. He first addressed himself to the London Deaf and Dumb Asylum, but after considerable correspondence he was refused admission to the asylum, except as ordinary visitor. The University and the Bibliothèque have however a marked Florentine character. The architect constantly uses the arch-headed window, divided into two lights by a centre- column, and avoids the characteristics of the late Italian styles,—whilst ornament of original character is freely introduced. But there, while the committee and master showed every sympathy with him, and would have been glad to assist him in his excellent object, there was an obstacle which it was found impossible to surmount. The teacher had learnt his system from the Masons. Bridewell [Bridewell, Thomas], and found impossible to disseminate it.
to impart the method to any one person intending to become a teacher.

Thus baffled, Gallaudet was compelled to try Paris. Here he met an Abbé Sicard, and a warm welcome. Everybody was freely open to him, and every means that could be devised was used to accelerate his acquisition of the desired knowledge. He was able to return to America before the close of 1816, and the Abbé Sicard cheerfully consented to Leonidas Clarke, who had been the private teacher of the pupils, and was then one of the most valued teachers of the institution (he had already been designated its "glory and support"), accompanying him to America. During his absence in Europe, the society had been incorporated; Mr. Gallaudet was appointed as president, and Leonidas Clarke as his head assistant, and on the 15th of April, 1817, "The American Asylum for the Deaf and Dumb," at Hartford, Connecticut, was formally opened.

The first pupil at the decisive head of the asylum until 1830, when he resigned from failing health. His devotion to his duties had been most exemplary, and his success as a teacher, we are told, was "uniform and preeminent." The system which he in conjunction with M. le Clerc ultimately established, and which has been adopted in the other asylums (of which there are now fourteen) in the United States, was founded on that of the Abbé Sicard, but with very considerable modifications. It is known as the American system. The main principle with Mr. Gallaudet was to impart the idea of much as knowledge as possible, by exercising him in describing things for himself, and to discourage the mere learning by rote; and the result was to stimulate the mind of the teacher, as well as of the pupil, in a remarkable degree.

Mr. Gallaudet's exertions were by no means confined to the deaf and dumb asylum. He took an ardent and active interest in the improvement and extension of common schools, and in the raising up of a superior body of teachers, and wrote several pamphlets on the subject. He also zealously advocated the adoption of means of imparting moral and religious training to prisoners; and he was an earnest proponent of the movement for improving the management of the insane. His last effort on this line of thought, but feeble health, he accepted in 1838 the office of chaplain of the state prison, "Retreat for the Insane," at Hartford; where it is stated, "the experience of each successive year furnished accumulating evidence of the usefulness of his labours, and the efficacy of kind moral treatment, and a wise religious influence in the mellioration and care of the insane."

He died on the 10th of September, 1851. About twelve months before his death, the good old man, and his colleague Mr. Clarke, had drawn from the great body of their deaf-mutes in America, as a testimonial of their gratitude, a service of plate each; and on the death of Gallaudet, his fellow-citizens proposed to erect a monument to his memory, as a mark of their sense of his services; but as soon as their intentions were known, the deaf-mutes urged that a more superior claim to the performance of that duty, and accordingly a handsome and costly monument was erected to his memory at Hartford, at the "sole expense of the deaf-mutes of the United States," the designer and the architect of the monument being both deaf and dumb persons.

The publications of Mr. Gallaudet are numerous, but chiefly pamphlets on the education of the deaf and dumb, and on other educational matters; lesson books; and articles in educational journals. He also wrote a number of sermons, and some books for the young, one of which, "The Child's Book of the Soul," had an extended popularity both in America and in England, and was translated into French, Spanish, Italian, and German.

(Garnand, *Tribute to Gallaudet*, 8vo, Hartford, U.S., 1852.)

**GALLE, POINT DE**, a town, port, and harbour on the south coast of the island of Ceylon, 75 miles S. by E. from Colombo, is situated in 5° 1' N. lat., 80° 16' E. long. The town is surrounded by a lovely circumference, and is situated at the Point de Galle. The harbour is formed between the point, which extends towards the east, and a piece of land sloping inwards from the west, thus forming a small bay. The entrance to the bay is about a mile wide, but as there are many rocks in it, a pilot is required to navigate it. A good anchorage, which is about the town is sheltered in the fathom's depth of water. There is a pier; a jetty was constructed in 1847, and a new wharf in 1853. The increase in the number of steam-vessels, having at the port chiefly to take in coals has caused various proposals to be made for improving the harbour, but funds are wanting. The fort, built by the Dutch, is upwards of a mile in circumference, and contains several large and commodious houses inhabited by Europeans. The town, or petiah, inhabited by natives, is exclusively a native place, and has a large population. There are schools here maintained by the government for the education of the natives. An iron lighthouse, constructed in London, was erected in 1846; the total height of the light above the sea is 209 ft.; the lighthouse is 90 ft. high, and the letters, &c., are forwarded immediately to Colombo, whence they are transmitted to all parts of Ceylon. Letters taken by steamers from Point de Galle reach Madras in three days and Calcutta in nine days. Bombay is reached by steamer in fifteen days.

**GALLIONELLA [MELONIER, S. R.]**

**GAMBIA COLONY**, the British settlements on the Gambia, a river in Western Africa. The source of the Gambia has not been definitely ascertained. According to the most reliable accounts it rises in the country of the Fouta-Jalon, very near and a little to the south of the source of the Rio-Grandes, in 10° 36' N. lat., 11° 18' W. long., in a valley surrounded by mountains. The river flows first east and then north until it reaches 13° 22' N. lat., whence it turns and flows south to 11° 18' N. lat., where, after having flowed upwards of 400 miles, it is less than 50 miles from its source. Its course is then generally north-west as far as 14° 30' N. lat., where it turns W. or W.N.W., and then S.W. to the sea, which it enters in 13° 30' N. lat., 16° 40' W. long. The Gambia has many afflictions, especially in the upper part of its course. The most remarkable on the right bank are the Ba Creek, the Neocalaba, the Niarico, the Nieko, the Jasur i, the Gular, the Armitara, the Gouna, the Port, the Jalista, and the Eropina, 45 miles below where the Gambia throws off a considerable branch named the Casmans, which by numerous channels flows into the St. Domingo. The width between Cape St. Marie and the island of Sangooma is 300 miles. On the left bank lie the rivers flowing from above the Rock of Barraconda, which has generally been considered to be 400 miles above Bathurst. The governor's party included Mr. Bage, the colonial engineer, Staff-Surgeon Kehoe, and Lieutenant Mostyn; they proceeded on small boats, accompanied by a canoes. In their progress they observed few signs of cultivation or of inhabitants along the banks. Near the junction of the Niarico the inhabitants of a town called Jallacosta waited upon the governor, soliciting the visits of the English; and the inhabitants of the trading station of Tattoo had been beneficially exercised in sabating the violence of intestine strife among the native tribes in the interior, and cultivating commercial intercourse, thereby promoting agricultural and industrial, and fostering conciliatory feelings amongst the natives. The latter was urged by the government to engage in, and Staff-Surgeon Kehoe vaccination has been brought into very extensive adoption among the native tribes on the Gambia.

The English have trading establishments at intervals along both banks of this river for many miles into the interior. The whole of the establishments are included under the title of the Gambia Colony. The colonial revenue for 1851 was £414. The exports from the Gambia are African tea, ship- timber, ivory, nutmegs, ivory hides, gum, sugar, tobacco, and hemp-wax. The values of the exports in 1851 amounted to £16,404, of the imports to 107,011. In 1852 the exports amounted to £17,806, the imports to 110,174. The number of vessels arriving at the colony during 1852 was 386, tonnage 29,274, of which 31 ships of 500 tons were British. The number and tonnage of ships cleared outwards during 1852 were:—Ships 260, tonnage 30,188, of which 30 ships of 4994 tons were British. The number and tonnage of vessels arriving at the colony during the first quarter of 1853 were:—Under 50 tons 49 vessels, tonnage 923; above 50 tons 14 vessels, tonnage 1270. Of the amount of exports for 1851 (186,404) the article of ground-nuts alone furnished 133,131l. value. The quantity of ground-nuts imported into the colony is extraordinary, and is annually increasing. On the 31st December 1853 were:—Under 50 tons 49 vessels, tonnage 923; above 50 tons 14 vessels, tonnage 1270. Of the amount of exports for 1851 (186,404) the article of ground-nuts alone furnished 133,131l. value. The quantity of ground-nuts imported into the colony is extraordinary, and is annually increasing. On the 31st December 1853 were:—Under 50 tons 49 vessels, tonnage 923; above 50 tons 14 vessels, tonnage 1270. Of the amount of exports for 1851 (186,404) the article of ground-nuts alone furnished 133,131l. value. The quantity of ground-nuts imported into the colony is extraordinary, and is annually increasing.
of whom travel hundreds of miles from the interior, and hire from the chiefs whose lands lie on the banks of the Gambia, such small portions of ground as their circumstances allow them to cultivate. After the produce of two or three years has enabled them to purchase supplies of European goods, they usually make up parties of from 20 to 100 strong and return to their homes in the interior. These migratory labourers are called 'tilliebunks,' or men from the east. They are posted as usual in the locality called at Bathurst, on the island of St. Mary, at the mouth of the river, whence the produce of the country is shipped for England, and at MacCarthy's Island. A colonial steamer has been stationed at Bathurst for some years, and has been of constant service in the sudden depopulation of MacCarthy's Island, and with trading stations on the banks of the Gambia. The land and sea breezes blow regularly over St. Mary Island for a considerable part of the year. The surface is a low plain with a slight decay in the north and east towards the centre, which during the rainy season is much inundated. The soil is sandy, with a very small admixture of loam. In the shade the thermometer does not rise above 90°. Water is scarce and not of good quality. Bathurst town does not stand more than 12 or 14 feet above high-water mark. Many good and substantial government and public buildings have been erected, as well as numerous handsome and convenient warehouses and dwellings; the remainder of the houses are rude and small. The European residents number about 50, but the number of European and American sailors and others visiting Bathurst every year is little short of 1900. There is a Roman Catholic chapel, capable of accommodating 600 persons, but no suitable place of worship for Protestants. The climate at any time is invigorating, and the health of those who frequent its shores is generally good. In the year 1871 the island was visited by from 24 miles in length, and stretches along the shore of the Atlantic, with an elevation above the sea varying from 50 to 90 feet. It is situated near Cape St. Mary, and being intended to be built upon by merchant and others, residents of Bathurst, it has been called colony.

The population of Gambia Colony, according to the census taken March 31st 1851 was 5693, as follows:—

Of the total population 82 were returned as engaged in agriculture, 320 in manufactures, and 278 in commerce.

MacCarthy's Island, the Janjan Bay of the natives, has an area of about 3 square miles, and is 150 miles from the mouth of the river, following its windings, in a populous district, 60 miles below the falls of Barracunda, up to which spot the river is navigable for vessels of 50 tons burden. Fort Gunjur, on the site of the town of that name, is the best fortified post on the coast. Like St. Mary Island, it is but little raised above the level of the sea, and both are in a great measure covered with water during the rainy season. Tropical remittent fever occurs at both places, but with most intensity at MacCarthy's Island. MacCarthy's Island has a rich alluvial soil, which in the dry season becomes a mass of burnt clay. The thermometer frequently rises to 106° or 108° in the shade.

The Wesleyan Methodists have schools at Bathurst, at MacCarthy's Island, and at Barra Point. The total number of scholars is about 600. The Roman Catholics have a school at Bathurst under the care of several Sisters of Charity.

GAME LAWS. Hares are no longer game, in the sense of being necessary to take out a certificate to kill them (11 & 13 Vict. c. 29).

GAMING. The numerous alterations which have been made in the law relating to contracts by, way of gaming, to gambling-houses, and to betting-offices, call for a repetition of what has been already stated on this subject. [GAMING.] Playing at cards, dice, or other games of chance, merely for recreation, and without any view to inordinate gain, is by the common law considered perfectly innocent. Not so the offence of gaming, which is defined in the 25th Henry VIII., as a tacit confession that the company engaged therein do, in general, exceed the bounds of their respective fortunes; and therefore they are to determine upon whom the ruin shall at present fall. It is a thing that the law may not have been made for. In this light, it is an offence not of the most alarming character, but by necessary consequence to promote public idleness, theft, and debauchery, among those of a lower class; and among persons of a superior rank, it has frequently been attended with the destruction of many of the most respectable families, an abandoned profession of every principle of honour and virtue, and too often has ended in self-murder. To restrain this pernicious vice among the inferior sort of people, the statute of 33 Hen. VIII. c. 9, was made; which prohibited all to all gentlemen the games of tennis, tables, cards, dice, bowls, and other unlawful diversions, such as lotteries in the fields, slide-thrift, or above-groat, cloysh-cayls, half-bowl, and cotting, unless in the time of Christmas, under penal pains and imprisonment. By the statute 19 Car. II. c. 7, it was next enacted, that if any person by playing or betting lost more than 100l. at one time, he was not compelled to pay the same; and the winner forfeited the value, one moiety to the king, the other to the informer. By the statute 19 & 20 Hen. VIII., it is further enacted that, the owner of the property or estate, the receiver of money won at play, or any person having any property or other rights, given for money won at play, or money lent at the time to play withal, shall be utterly void; that all mortgages upon the same consideration, shall endure to the use of the heir of the mortgagor; that, if any person at any time hereafter, shall at any time commit the like offence, up to the value of any person who used to recover it by action; and in case the loser did not, any other person might sue the winner for treble the sum so lost; and the plaintiff might by bill in equity examine the defence of the defendant himself, and that he had no privilege of parliament should be allowed. The statute further enacted, that if any person by cheating at play should win any money or valuable thing, or should at any time win more than 104l., he might be indicted thereupon, and that on conviction of the same crime the accused shall not only forfeit five times the value to any person who used to recover it, and in (case of cheating) should be deemed infamous, and suffer such corporal punishment as in case of willful perjury.

The effect of these and of various other statutes, provisions, which need not be enumerated, was that all gambling securities, even when transferred to purchasers for a valuable consideration, and without notice of their illegal origin, were altogether void; a result under such circumstances often greatly with great advantage; the law was therefore altered by statute 6 & 7 Will. IV. c. 41, by which securities given for considerations arising out of illegal transactions are declared not to be void; but to be deemed as having been given for an illegal consideration only, the object and effect of this enactment being, to make the present holders of such securities. Finally, by the statute 8 & 9 Vict. c. 109, repealing the Act of Hen. VIII. (so far as relates to the prohibition of the games of skill therein mentioned, together with the statutes of Charles II. and Anne, and several others), every person who by any fraud, unlawful device, or ill practice, in playing at or with cards, dice, tables, or other game, or in bearing a part in the stakes, wagers, or adventures, or in betting on the sides or hands of such playing, or in any other similar way, in any sort of pastime, exercise, shall win from any other person any sum of money or valuable thing, is guilty of obtaining it by a false pretence, with intent to cheat or defraud; and being convicted thereof, is punishable accordingly. By the same statute all contracts or agreements by which the owner of any wagering, are declared to be null and void, and no suit is to be maintainable for recovering any money or valuable thing alleged to have been won upon any wager, or deposited as security for wages, is to be enforced. It also enacted that it shall not apply to any subscription, contribution, or agreement to subscribe or contribute for or toward any plate, prize, or sum of money to be awarded to the winner of any lawful game (such as a foot-race or dominance), sport, pastime, or exercise.

For the suppression of gaming-houses, many statutes have been passed from time to time. The Act 33 Hen. VIII. c. 9, first prohibited the keeping of any gaming-house for profit, under a penalty of 40s. a day; and subjected any person
handing and using such gaming-houses to a penalty of 6s. 8d. The same statute, and also the statute 30 Geo. II. c. 24, inflicted penalties as well upon the master of a public-house, wherein servants were permitted to game, as upon the servants themselves, who were found to be gaming there. Special provision was also made of the rewards made by the statute 3 Geo. IV. c. 79; and now, by the statute 9 Geo. IV. c. 61, the unlawfully and knowingly permitting of any unlawful game, or any gaming whatever, in a public-house, may involve a forfeiture of the licence as well as the punishment of the servant. A list of specious and sometimes voluntary, but not authorized, penalties, under a penalty, to be obtained annually, at the general annual licensing meeting of the justices of the peace, by such persons as keep public billiard-tables and bagattelle-boards, or instruments used in any game of a like kind.

During the reign of King George II, all private lotteries by tickets, cards, or dice (and particularly the games of faro, basset, ace of hearts, hazard, passage, roolly-polly, and all other games with dice, except back-gammon), are prohibited under a penalty of 200l. for each that shall erect such lotteries, and 60l. a time for the players; and by the statute 42 Geo. III. c. 119, games called little-plays are declared to be common and public nuisances, and a penalty of 200l. is imposed upon persons keeping any office or place for the purpose of a lottery or for any lottery or lottery instrument, not authorized by parliament. Public lotteries, unless by authority of Parliament, and all manner of ingenious devices, under the denomination of sales or otherwise, which in the end were equivalent to lotteries, had been before prohibited by a great variety of heavy penalties under several acts of parliament.

The effect of these statutes being to render all lotteries illegal, whatever might be the object, it was found necessary to pass a special Act for the protection of those lawful amusements called Art-Contests, having for their object the promotion of a taste for the fine arts, and accordingly, by the 9 & 10 Vict. c. 48, any voluntary association constituted for the distribution of works of art by lot, is to be deemed legal; provided it be incorporated by charter or by proclamation of the association and its rules be submitted to and approved by of a committee of the Privy Council.

The statute 13 Geo. II. c. 19, to prevent the multiplicity of horse-races, another fund of gaming, directed that no plates or matches under 50l. value should be run, upon penalty of 200l. to be paid by the owner of each horse running, and 100l. by such as advertised the plate. But in consequence of a number of vexatious actions having been brought under this statute, it was, so far as it related to horse-racing, repealed by the statute 3 Vict. c. 6. The effect of the latter was to provide that the provisions of the statutes 33 Hen. VIII. c. 9, and 13 Geo. II. c. 19, and of the exception before mentioned in the statutes 9 & 9 Vict. c. 109, is to place all bargains relating to horse-racing on the same footing as other bargains.

"But," as observed by Blackstone, "particular descriptions will ever be lame and deficient, unless all games of mere chance are at once prohibited; the inventions of sharpers being swifter than the punishment of the law, which only hunts them from one device to another." No sooner were contracts as to horse-racing legalised, than an immense number of petty gaming-houses sprung up, under the name of betting-offices. The demoralisation which was found to be the immediate result called for the interference of the legislature, and the statute 16 & 17 Vict. c. 119, was accordingly passed, expressly for the suppression of these haunts of vice. Under this Act, the owner or occupier, or any person using such places, may be summarily convicted, and either punished by a fine of 100l. or, by a penalty of 50l., or two months imprisonment; and without hard labour, for any period not exceeding six months.

Persons receiving deposits on bets in such houses incur a penalty of 50l., or three months imprisonment with or without hard labour, for the exhibition of placards or hand-bills, or the advertising of bets, in order to increase a penalty of 50l., or two months imprisonment; and summary powers are conferred on magistrates and constables to enter and search suspected houses.

It is added here that a bankrupt is not entitled to a certificate, or the certificate if granted is void, if he has lost 20l. in any day or 500l. a year by any sort of gaming or wagering.

Gaming-houses are public nuisances, and the keeper thereof may be indicted at common law. To encourage the prosecution of such pernicious establishments, the statute 25 Geo. II. c. 36, as amended by 58 Geo. III. c. 70, imposes on the overseers of the parish, or the constable, the duty of prosecuting, whenever two rated inhabitants depose before a magistrate to their belief of the fact of the house being a gaming-house, and enter into recognizances to give material evidence thereof. The costs of the prosecution are, in this case, allowed out of the fund for games. If two or more of the inhabitants who originated the proceedings are entitled to 10l. each. To facilitate such prosecutions, it is expressly provided that the person appearing or acting as master, or as having the care and management of any gaming-house, shall be held guilty, and also the master of the house of any offence is punishable by a fine, to which, by the statute 3 Geo. IV. c. 114, imprisonment and hard labour may be added.

The more recent enactments of the statute 8 & 9 Vict. c. 109, and 17 & 18 Vict. c. 38, have still further facilitated the prosecution of this offence. The owner, occupier, or keeeper, and every person in any manner conducting the business of any common gaming-house, or advancing or furnishing money for any purpose of gaming, may now be convicted on the oath of one witness, before two justices of the peace; and in addition to the penalties of the Act of Henry the Eighth, be fined in any sum not exceeding 500l., or in the discretion of the justices, be committed to the house of correction for such a term not exceeding twelve months. No proceeding under these statutes is a bar to an indictment being preferred; but no person summarily convicted under them can afterwards be proceeded against by indictment for the same offence. To remove any ambiguity on this point, the same Act declares that the proceedings mentioned statute expressly provides that any person examined as a witness, either before the justices or on the trial of any indictment or information touching any unlawful gaming, and who shall receive from the court a certificate of the appointment of that person as a witness, shall be protected in giving evidence as to such criminal proceedings, forfeitures, and disabilities in respect of such unlawful gaming, while the second statute expressly enables the justices to require persons apprehended in gaming-houses to be brought before them, and to be examined as to the circumstances of such apprehension.

Facilities are given by these statutes for entering forcibly houses and rooms suspected to be used as places for gaming; and for the arrest of persons found there; heavy penalties being imposed on persons obstructing the entry of constables, and the fact of such obstruction being itself made evidence of the house being a common gaming-house. To prevent persons evading punishment by pretending that the house was only open for the use of subscribers, it is sufficient to prove, in default of other evidence, that the house was used for the purpose of the vice; and he who keeps, or who allows to be kept by him or by any other, the places mentioned above, may be punished for any gaming played in the house, and the court may order the house to be searched, and the goods to be removed and sold at public auction.

(Blackstone's 'Commentaries'; Mr. Kerr's edition, vol. i. p. 188.)

CAMPSONYX. [FALCONERD.] GARAY, JA\'N\'OS, a popular modern Hungarian poet, was born in 1812, at Szegard, in the county of Tolna. He first attracted attention in 1834 by his heroic poem of 'Caster,' written in imitation of Vörösmarty's epic; and continued in reputation for some years, during which he was one of the favourite contributors to three or four of the Hungarian annuals, and gained several prizes from the societies which offer premiums for successful contributions to the Magyar drama. He gained a scanty subsistence by literary labours of less importance. "Handboox of the Hungarian Dialogues," and by editing a sort of almanac, and at one time a newspaper. In his later years, when his health was bad and he had almost lost his eyesight, he and his family were received by eminent persons in society, and had a seat in the same room as himself in the university library of Pesth, where he died after a long illness, on the 5th of November, 1853. He was a member of the Hungarian Academy. His last productions are 'Elizabeth Batori,' a play in 5 acts; 'Christina Maria,' a tale of ancient times; and 'A Page's Tale,' a collection of poems called 'The Pearls of the Balaton Lake;' and 'Saint Ladislaus," an historical poem. He was enthusiastically patriotic, and took an active part in the progress of Hungary during the Hapsburgs, and was almost looked upon as its golden age, from 1848. In his lyric poems he takes by preference national
subjects and these connected with modern improvement, such as the power of locomotion and the wonders of railways.

GARNSHTEEN. Where the debts owing to a judgment debtor are attached to answer the claim of the judgment creditor [Attachment; Attachment of Debts, § 2], the judgment debtor is called the Garnishee, a designation derived from the process of garnishing in ancient custom. In the Lord Mayor's Court of London, the Tolsey Court of Bristol, and the Borough Court of Exeter. The garnisher may be examined as to his indebtedness, he may dispute his liability, or he may pay the debts to the judgment creditor, who can effectually resist the latter if he does so. ('Common Law Procedure Act,' 1854.)

GARGANTUA. [Lancashire.]

GASES, LIQUEFACTION OF. [Chemistry, § 1.]

GASTROPODS. [Marine Molluscs.]

GAUTHERIA, a genus of Plants belonging to the natural order Ericaceae. It has a 5-angled or 5-toothed calyx, bibracteate at the base, after flowering becoming large and succulent, and covering the capsule with a baccate coating. The corolla is ovate, ventricose, with a 5-angled, rove-like, transparent at the base. There are 10 stamens, inclosed, with flat filaments; anthers bifid at the apex; lobes binate. The hypogynous scales 10, usually united at the base. The ovary half inferior. The capsule 5-celled, with a loculicidal dehiscence.

G. procumbens, Partridge-Berry, Chequer-Berry, Booberry, Mountain-Tea, is found on sterile sand and gravel in mountainous forests in the driest situations in North America. It has a horizontal woody rhizome, often a quarter of an inch in diameter. The stems are erect, reaching a height of 10 to 20 inches, with a robust calyx, high, round and somewhat downy. The leaves are scattered near the extremities of the branches, evergreen, coriaceous, shining, oval, or ovate, acute at both ends, revolute at the edge, and furnished with a few small serratures, each termi- nating in a minute gland, light green above, dull and downy below, and round downy stalks. There are two concave heart-shaped bracts. The calyx is white, cleft into 5 roundish acute segments. The corolla is white, urceolate, 5-angled, contracted at the base, the tube dilated, the limb 5-angled, obtuse, blooming on round downy stalks. There are two concave heart-shaped bracts.

G. smilacina, a plant of the same family as above, but smaller, and with less conspicuous flowers. It is found in the mountainous parts of North America, and is cultivated for its medicinal properties.

GAUDIE, HENRY. [Edinburgh.] A well-known brewer, who has made a considerable name for his ale, and is particularly noted for his skill in brewing 'tawny port' ale.

GAUSS, CARL FRIEDRICH, one of the most celebrated mathematicians of his day, was born at Brunswick, April 23, 1777. He displayed early such marked talent for the abstract sciences that the Duke of Brunswick, Charles Ferdinand, undertook the charge of the boy's education. He afterwards wrote a thesis which he maintained in 1799, before obtaining his degree of Doctor, he evinced his talent by analysing the previous methods for proving the truth of the fundamental theorems of algebra in a manner on which no one else could follow. In the same year he published his 'Demonstratio nova theorematis omnem functionem algebraicam rationalem unam variabilis in factores reales primi vel secundi gradus resolvi posse'; and in 1801 this was followed by his 'Dis- theoria motus corporum coelestium,' published at Hamburg, in 4to, in 1809; to which Professor Paucker added, in a separate pamphlet, a geometrical formula, more definitely proving the truth of the principle of the curvilinear triangulation upon which Gauss' method depends. This work contributed to the succeeding more exact and useful application of the astronomical observations to which, about this time, the attention of the scientific world began to be directed. His 'Theoria combinationis observationum errore parvo accנטר is' (1819) was published at Leipzig in 4to, with the supplement, issued in 1828 from the same place, was a great addition to scientific knowledge.

On the completion of the Göttingen Observatory, Gauss devoted himself to astronomical observations. On the death of W. Bode, the Astronomer Royal of the Danish Academe of Sciences, the latter's place was filled by the Danish admixture of an arc of the meridian to the kingdom of Hanover, he invented the means of making distant stations visible, by reflected sun-light, by an instrument known as the 'Glocke.' He was also occupied with investigations as to terrestrial or telluric magnetism, for which purpose the government caused a building to be erected for his experiments, near the observatory. By the labours of himself and W. Weber, the science of telluric magnetism assumed a new and important phase. The theory was explained by them in conjunction in the Transactions of the Magnetic Union, under the title of 'Resultate aus dem Beobachtungen des Magnetischen Vereins in Jahre 1836, herausgegeben von C. F. Gauss and Wilhelm Weber,' published at Göttingen in 1838, in 4to, and in 1840, with an 'Atlas des Erdmagnetismus, nach den Elementen des Theorie entwirft.' In 1841 he published at Göttingen his 'Disquisi- tiones analyticae circa limites serierum infinitarum,' in 4to. His latest labours were directed to the theory of geodesy, the first essay of a series upon which he published at Göttingen in 1844, under the title of 'Untersuchungen über Gegenstande der höhern Geodesie.' In this, in a modest pride, he speaks of the trigonometrical admeasurement as "partly executed by myself, and partly under my guidance." This was contributed to the 'Transactions' of the Royal Scientific Society at Göttingen, and appeared in the second volume. He died on February 23, 1855.

We do not attempt to give a complete list of Gauss's works: he contributed many papers to scientific publications, but the following are among the most interesting that have appeared separately in addition to those already mentioned:—Methodus generalis circuli quadratum solvi determinandi expli- cat,' Göttingen, 1808, 4to; 'Disquisitiones generales circa superficies curvus,' Göttingen, 1826, 4to; 'Theoria residuo- rum biinquadricorum Commentatio prima,' Göttingen, 1828, 4to; 'Intensitas vis magneticae terrestrialis ad mensuram absolutam reducere ad magnitudines mensurabilem,' Göttingen, 1830.

GAY, G. [The], a poet of the Romantic school, was born at St. George's, in the department of Haute-Vienne, on December 6th, 1778. He was educated at the Polytechnic School, where his assiduity and talents gained him the friendship of Berthollet. On leaving the school he entered the scientific department of Les Ponts et Chaussees. The expansi- bility of the gasses was at that time a subject exciting much attention; and Gay-Lussac gave the law of dilatation, and showed its constant uniformity. His application to the subject led M. Charles, a scientific physician, to recommend...
him the use of the balloon, just previously invented, as an excellent means of testing some of his theories, of making fresh experiments, and of at least exciting public attention by the splendor of the process. In conjunction with M. Biot, he made the proposal to the government; Laplace and Berthollet supported it; and M. Chaptal, then Minister of the Interior, gave them the balloon which had been rejected by the government. This he had it refitted at the public expense. Furnished with chromatographs, thermometers, barometers, hygrometers, electrometers, compasses, and papers and pencils, Messrs. Gay-Lussac and Biot ascended from the garden of the Conservatoire, near the Rue de l’Observatoire, and the immense elevation attained was 3977 feet (4435 yards) above the Seine. M. Biot was affected with giddiness; but Gay-Lussac, by his experiments, ascertained that the influence of terrestri- nal magnetism on the compass was nearly as great as on earth; that during works of gold and silver, as with M. Aрагo of the ‘Annales de Physique et de Chimie,’ with several other official employments connected with the manufacturing industry of France. After a long life of useful labors, and an Enjoyment of ninety years, M. Gay-Lussac died May 9, 1850, at Paris, in the mansion provided for him in the Jardin du Roi.

GAYAL. [Oz.] GEDRITE. [Mineralog.] GEL. [Bacteria.]}

"I was,” said by a Swedish critic to be equally eminent as a poet, a thinker, and an historian, was born at the iron-foundry of Ränster, in Ränster chapeley, province of Wermeland, Sweden, on the 12th of January, 1783. His father, the proprietor of the foundry, was a follower of the Reformation, and had emigrated from Sweden to Austria in the time of Gustavus Adolphus, and by establishing foundries had peopled the district. Geijer, in his ‘Minnen,’ or ‘Reminiscences,’ has given a vivid description of the wild country of the carriage, and the beauty of his native land as they rolled in it, to both of which he was strongly attached. At twelve years old he was sent to the school at Carlstad, five Swedish miles south of his birth-place, and at sixteen to the University at Upsal; during his residence at which he never enjoyed nothing so much as his frequent visits home, where he used to declare his conviction that the solemn academical disputations of Upsal would be the laughing-stock of future ages. At the age of twenty he was still without a degree, and when he took leave of his masters, this was the answer they gave him. He filled himself with power, and, after some studies, applied to a family of consideration to secure him the place of tutor, they received him for that inquirers who had been made at the university as to his character, and that he should not have been "found." His version of the same name, he was "imperfect copy of Dalin’s ‘History of Sweden,’ at the Round, for, latterly, they are the few who seem to possess himself of some paper, which was scarce in those quarters, and as fast as he wrote his essay, concealed the sheets in the unsuspected hiding-place of an old clock-case. It needed some contrivance to get the essay sent by post without taking any one into his confidence, but this too was done. Some months after his sister asked him what made it turn so red on a sudden as he was reading the newspaper. He had come on an advertisement requesting the author of ‘Memoire sur la Cynogone’ to send his last work to the printer, and he had written to him, which he had selected—to make himself known to the Academy. He had won the prize, and from that day was looked on in a different light by his family and all his friends. In the next year, when he visited Stockholm, he was one of the leading literary men, and universally regarded as a youth of high promise. In the same year (1804), on a visit to his native Wermeland, he became acquainted, on a hunting excursion, with another young Wermelander, a student of the University of Upsal, and they took a ramble together, sleeping occasionally in barns, and keeping up a continual disputition. This student, who became a friend for life, was Esaia Tegnér, afterwards Bishop of Wexio, now universally regarded as the greatest poet whom Sweden has produced. ‘We never talked together, then or afterwards,’ Geijer said in later life in his eulogy on Tegnér, ‘without disputing; and as we never came to agree, perhaps the solution may be, that we never understood one another. How this may be, I cannot tell; I know not, but I at least believed that I understood him.’

In 1806 Geijer took his degree, and soon after obtained a post in the National Archives; but he was anxious to travel in foreign countries, and in 1809 obtained his wish by visiting England, and afterwards, as ERRICK, tending tutor to a youth of the name of Von Schinkel. He stayed about a twelvemonth in this country, two months of which were spent in studying English at Stoke Newington. Several of Geijer’s letters from England were printed by himself in his ‘Minnen,’ in 1814; and was a frequent contributor to the Athenaeum, and to some of his writings now publishing. In one of them, dated from Bath in 1810, and first printed in 1855, he says, ‘I came to England with strange prejudices against the people. It is a nation, I thought to myself, in which a love for gain and a narrow selfishness has quenched all that is beautiful and
noble. Mine was a Swedish notion of selflessness, drawn from an imperfect state of society, where the connection between Sweden and its colonies was pretty obvious. Here every man knows that connection; and there is no honester man in the world than the selfish industrious Englishman, from the merchant to the day-labourer. This result may be owing to prudence as well as to principle, but neither he nor his brother, who shared his home, admired the honour and the mutual confidence that prevail in commerce and in life." On his return to Sweden, Geijer was soon engaged in the editorship of a magazine having the name of 'The Viking,' and became editor of 'The Iduna,' a popular ballad magazine containing numbers of poems by Geijer himself. The 'Iduna' contained in its earliest numbers poems by Geijer—"The Viking," "The Last Champion," &c.—which were full of vigour and spirit, which became immediately popular, were translated into Danish and German, and still retain their place in all selections of Swedish poetry. In subsequent numbers the early cantos of Tegnérs's 'Friholth' appeared for the first time. As in the case of many other Swedish periodicals during the period of the 'Iduna,' however successful, for an indefinite space of time: it was brought to an end after ten numbers, and the society of the Goths, which was painfully kept up by the exertions of Adlerbeth for many years after the other members of the society had dispersed, was dissolved when he died in 1844. Geijer put forth, in 1813, a translation of 'Macbeth;' and between 1814 and 1816 was associated with Atelius in the publication of a collection of Swedish popular ballads, 'Svenska Folkvisor,' in 3 vols., to which however Geijer contributed little more than introductory matter. He had held from 1810, when he was elected during his absence in England, a subordinate post in the University of Upsal, and for some years was in search of a position of some importance. He was appointed adjunct or assistant to Fant, the professor of history at the University of Upsal, on his retirement; he then married a lady to whom he had been engaged before his journey to England, and in the next year, on the death of Fant, he succeeded to the full professorship. His first lectures had an unexampled popularity, and the lecture-room was crowded, not only with students, but with the best society of Upsal, including ladies. These early lectures were different both in matter and manner from those which his more mature years brought him to deliver. He grew more profound he became less popular, but he still continued the pride of the university and the favourite of the students. His success with the elogy of Sten Sture had prepared the way for the recognition of these works by the public. He was charged with wanting, and as a professor he was not remarkable for regularity in the discharge of his duties. His musical tastes interfered a good deal with his other pursuits, and it was remarked that when he had once got to a pianoforte, it was not easy to get him away from it. He had also frequent leave of absence for the purpose of prosecuting historical researches. One of the most prominent incidents in his academic life was an academic triall to which he was subjected on account of his theological opinions. In an edition which he published about 1820, of the works of Thordal, a Swedish philosophical speculator, some passages in the introduction by Geijer, which was entitled 'A Philosophical or Unphilosophical Confession of Faith,' were regarded by some of his colleagues as hostile to the doctrine of the Trinity, and the author was denounced to the university authorities; but a long examination terminated in an acquittal, which was celebrated as an important triumph of liberty of thought and liberty of the press in Sweden. Geijer's connection in the society of the Church-Christian, I am not a Bible-Christian; I am, so to speak, a Christian on my own account;" and he concludes a statement of his way of thinking in theology with the declaration, the same year, 'I am engaged in a trial to which he had been subjected did not prevent his being twice offered a bishopric, that on the second occasion being in his native diocese of Carlstad, a distinction the more flattering that in Sweden a bishop must in the first instance be nominated by the clergy. He declined both occasions. "Perhaps if I accepted," he wrote to a friend, "they might have a blameless middling bishop, but there would be an end to Erik Gustaf Geijer. It is not pride that makes me regard with horror of this dignity, this new path, these new duties. Better been working in the circle where I am at home, and know that I work to some purpose. For the University of Upsal I am somebody. That would lose more than Wermeland gained. Geijer was in 1819 elected a member of the Royal Swedish Literature Society as the head of Swedish historical literature. He planned a great history of the country, to supersede that of Dalin and Lagerbring, who have been for Sweden what Hume and Gibbon are for Great Britain; and he was universally acknowledged that his introduction to the great work was a volume of 'Svea Rikes Häfder,' or 'Records of Sweden,' promised a master-piece. Unfortunately, the great work was never carried further. Before proceeding with it the author was invited to present an address before the new Poor Laws and their bearing on Society, 'Svenska Folkskets Historia,' for the general collection of the histories of Europe, set on foot by Leo and Uckert; and this was carried before 1843, in three volumes, to the death of Queen Christina, but there it stopped. The professor, in place of continuing it, was occupied in examining the papers of Gustavus III., which the king had bequeathed to the University of Upsal, in a chest not to be opened till fifty years after his death. The work founded on these, 'Kongens: Vingodsräkning,' 'The Carnation of Kings,' 'Jennförsökel af E. G. Geijer' (3 vols., 8vo, Upsal, 1843), disappointed the public expectation, but more owing to the insignificance of the royal legacy than to any deficiency on the part of the editor. Geijer was occupied with speculations in politics and political economy. Twice he was the representative of the University of Upsal at the diet, and while on the first occasion he was a warm defender of monarchical power, in the second (1830) he saw cause to modify his views, and lost the approbation of several of his opponents. He was a change of opinion in favour of progress and liberalism, which he avowed and defended in a periodical called 'Litteraturbladet,' written by himself. His views of pauperism were developed in a series of pamphlets and in 'Peter Laws and their bearing on Society, a Series of Political and Historical Essays,' which were published in English (Stockholm, 1840) as well as Swedish, and of which the English version, as it bears no translator's name, and has marks of a foreign hand, may possibly be from his own pen. A dissertation on the history of Sweden during the 'Frihetstid,' or 'Freedom-Time,' as it is called, which extended from the death of Charles XII. to the revolution in favour of regal power which was forcibly effected by Gustavus III., is the last of Geijer's works of much importance. The aristocratical government did not pass unquestioned, and were the subject of a controversy with Fryxell. During about thirty years Geijer continued one of the literary journals of Sweden, and his name was distinguished. He was the intimate friend of Tegnér and Atterbom, had a correspondence with Frederika Bremer, and wrote both verses and music for Jenny Lind. In 1846 his health began to break, he was obliged to pay a visit to the Schlungenbad of Nassau, and resigned his professorship. He died at Stockholm on the 23rd of April, 1847—a year which was fatal to many of the literary celebrities of Sweden. A collected edition of Geijer's works was commenced soon after his death, but is still incomplete, though advanced (in 1856) to thirteen octavo volumes. A life by his son, Knut Geijer, is prefixed to the first volume, but before the second sheet had been printed the writer suddenly died. Most of the works of Geijer have been already mentioned. The most important is undoubtedly his 'Svenska Folkskets Historia,' of which an English translation by J. H. Turner was published in London, and the first volume of a continuation of which by Carlsson was issued in German, in Leo and Uckert's collection. Geijer was in fact a poet of the age, and occupied with shorter pieces, articles in periodicals and papers read before the Swedish Academy, of which he became 'One of the Eighteen' in 1824, and was afterwards president. Many of the letters in his works are posthumously written, in which he was the author as yet not reprinted, but several of them—one in particular on the Swedish colonies in America—are of considerable interest. His letters and his minutes of conversations with Bernadotte, with whom he seems to have been a favourite, were first printed in the collection, and embrace much that is worthy of notice and
preservation, especially when taken in conjunction with his method of "uninfluenced," perhaps the most attractive of production, but one which like so many others was left un-
finished. It should be observed that Geiger had not only a taste but a talent for music, and enjoyed some reputation as a musical composer, a volume of music having been published in one edition and in blank.

GEIGE. [CHEMISTRY. S. 2.]

GELATIN. [Tissues, Organic, S. 1.]

GENERATIONS, ALTERATION OF. During the course of development of many of the lower animals fluid passes into the sex ducts, which not only pass through various forms, as is seen in the insect tribes [Insecta], but at certain stages of their growth they possess the power of multiplying themselves. The individuals which are thus produced have been called 'eggs,' and the whole series of phenomena associated with this mode of reproduction have been called by its first expounder, Professor Steenstrup, an "alteration of generations." This phenomenon has been particularly observed in the Asciidae, Entozoa, Polyzoa, Salpoa, and Forctidinae. In the various articles on these families of animals, their mode of development is described. As however this subject is one of general interest, and very imperfectly understood, we take the opportunity of reproducing here Professor Steenstrup's genera-
tions, from a translation of his work published by the Royal Society:—

"The mode of development by means of 'nurses,' or intermediate generations, is thus seen to be no longer an accidental phenomenon in nature. The circumstance of an animal giving birth to a progeny of individuals which, either itself or in its offspring returns to the form of the parent animal, is a phenomenon not confined to a single class or order of animals; it is a characteristic of nature, and one by which it has not been observed. It would consequently appear that there is something intrinsic in this mode of development, and that it occurs as it were with a certain necessity; on which account it will undoubtedly soon be recognized in the whole system of nature, and be studied as a science. It will no longer be considered as something paradoxical or anom-
alous (as we have hitherto been too much inclined to esteem both it and the phenomena in which it is exhibited), it must be in harmony with the rest of development in nature, in which the fundamental principle of this course of development must also be elsewhere expressed, although it may be displayed in a form under which we shall less readily perceive and recognize it. This is seen when we trace the modifications, the intermediate steps, and the whole process of the development of the species, and whilst contemplating it through the phenomena in which it is manifested, we comprehend it in its true light.

"We collect and record in one view the whole system of development by means of 'nursing' generations, as is exhibited in the Bell-Sized Polypes (Comes), the Claviform Polypes (Coryne), Medusa, Salpoa, Vorticellae, and Entozoa, it appears as a peculiar and consequently as an characteristic feature of this course of development, that the species (that is, the species in its development) is not wholly represented in the solitary, full-grown, fertile individuals of both sexes, nor in their development; but that to complete this representation, supplementary individuals, as it were, of one or several preceding generations are requisite. Thus the distinction between this course of development and that which is generally recognized in nature, in which the species is represented by the individual (of both sexes) and its de-
velopment, is the want on the part of the individuals of a complete representation of the various phases of the species, and of a specific individuality, if I may so express it. If now we agree to regard such an incompleteness in the individual as the essence of this development, we shall comprehend its significance in nature, as we have thoroughly considered this course of development and the various phases of instances, is ad-
duced in the foregoing pages, and the many gaps in the series of observations. Thus we see the greatest incomple-

teness and the highest degree of mutual dependence in the Comes, and similar Polypes, in which the generations representing the unity of the species are very unlike each

other, and in which all the individuals are fixed, as it were, into an outward unity, or into a set of Polypes. They exist, organically connected with each other, and are normally free only in their first generation, and indeed only in their earliest stage of development, and only for a short time, since the free-swimming ciliated embryo swims about in the water at most only a short distance and dies. In order to realize the foundation of a new polype stem. In the Comes, or clavi-
form Polypes, the organic connection between the individuals and generations is rather more lax; the perfect gemmiparae or ovigerous individuals are usually more free, often even being solitary. In the Medusa, the whole structure of the Medusa is still fixed but more active and mobile in its parts; the individuals of the perfect generation leave the 'nursing' animal while still very small, and undergo remark-
able changes after they have become free and are swimming freely about; both generations of the Salpoa, finally, are free, and free swimmers, only the individuals of one of them are organically connected with each other; they have however no common organs (in the full-grown state), and if my expla-
nation of the alternate generation of the compound Aecidises is correct, it is likely that in the Salpoa there is a still further separation of the Salpoa at a somewhat lower stage; the individuals of the one generation are organically connected, without having a common organ; but both generations are fixed."

"In the Cestodes the generation of perfect individuals constitutes externally a unity; they are only successively 

regulated and governed by different periods. They advance in a certain manner, their whole existence is through-

connected with the 'nursing' animal. In some of the Tremato-
sodes, the later generations remain within the earlier until they have attained their full development; in others they separate themselves from the 'nursing' animal; they change, and undergo a complete metamorphosis; in some of these latter, the earlier generations are transformed into motionless, and, as it were, lifeless cysts, whilst in others they remain free and active (the Proteo, and the 'parent nurse' of C. oesophagum and C. ehrenstii) but retain during their whole life a form which, at most, resembles the larve of the more perfect generation. In this way an advance in a certain direction may indisputably be observed."

At the same time, at the outset of the present treatise we have already mentioned that no distinction is to be made as regards the interior, but also with respect to the exterior: 

form a stationary colony; after which the generations are detached more and more from each other, and become at the same time more free; and, finally, all the individuals constituting each generation acquire the power of free locomotion. In this latter stage, or that of freedom and perfection, we found the development of animals which are certainly no longer attached to immo-

bile objects at the bottom of the sea, but live burrowing in other animal organisms, and belong not to the sea but to fresh water. In a still higher and more free stage than this we observe the development of animals which do not belong to the water, but to the air, in that which occurs in the Apus. In the progress of its development through a series of generations has been already long known. In the spring, for instance, a generation is produced from the, which grows and is metamorphosed, and without previous 

fertilisation gives birth to a new generation, and this again to a third, and so on. Thus the seeds of many and certain species even as many as nine such preliminary genera-
tions will have been observed; but at last there always occurs a generation consisting of males and females, the former of which, after their metamorphosis, are wholly 

different from the latter, and the daughter generation takes place, and the long series of generations recommences in the next year, and in the same order. All the individuals are free, and enjoy the power of free locomotion, and undergo a complete metamorphosis. Here, however, we have other animals which, after metamorphosis, inhabit other organisms; at most they are only externally parasitic, and on plants alone; the phenomena of this mode of develop-
ment are no longer exhibited by Entozoa, but by Entozoa, and the course of development is in itself: but in the external, more free, and nother form in which it is
Now exhibited, the endeavours to attain something higher is manifest. Each line or gesture of the worker brings its offering nearer to the perfect form aimed at; but the achievement of perfection is effected only by means of the ‘nursing’ by special animals, and is committed to the still and quiet activity of an organ, without the nursing animals themselves being largely or completely spent. Any delay, any lack of precision, and not an expression of the will. In all parts of the animal kingdom we see the instances of the still, quiet, and unconscious activity of the animal being developed into voluntary actions, which are undertaken by it from an internal, involuntary cause of action, on its own initiative; and this is the case in this instance. The development and mode of feeding or nourishing the young, exhibited in its course, of Bees, Wasps, Ants, and Termites, affords a direct example of a form in which the care of the young is provided for, by the voluntary action of numerous individuals for the benefit of that object. Those of the young which are to be developed into the more perfect fertile individuals are not protected in the body of the foster-parents, nor is their nourishment secreted by one of the organs; both protection and food are afforded them by means which are brought about by the conscious activity of the ‘feeders.’ The Wasp, for instance, or the Wild Humble-Bee, which has been impregnated in the autumn, and has afterwards sought a shelter to protect itself and its eggs till the spring, is a provision in which it builds cells and deposits its eggs. From the eggs proceed larvae, but the insects into which these larvae are metamorphosed, are not fertile; they are barren, and all their faculties are directed to the assistance of the parent, to the care of the kind of cells in which the young are provided, to tend the development of the females, in order to which some of their external organs are transformed, and to the erection of a better habitation and cells, into which they convey the eggs of the female, and the food of the young. The male insects, however, they contain a better sort of food, are erected for a later and less numerous progeny of eggs; and again in others, which are more roomy and provided with the best kind of food, but of which there is only a few, is the last brood of the female developed, in which the provision is in the proper individual, from the second the males, and from the third the females; after undergoing a metamorphosis, the males and females fly away, impregnation takes place, and the males die; the females however return, and the whole multitude of barren individuals, which at the same time perform the duty of feeding the young, build cells for their various progeny of eggs, and nourish the three forms of larvae which proceed from them. In this way the inhabitants of the colony become very numerous; nevertheless they all die in the winter; the fertile females alone remain alive, and propagate the species the year following, under the same development of alternating broods, the earlier of which is always by far the most numerous, and assists in the development of the species. The Termites, the same thing occurs; the many thousand individuals which constitute one of these colonies are principally ‘feeders,’ or individuals which have originated in the preceding divisions of the eggs of the females, and in these is exhibited, even with greater precision, a more marked division of labour in the feeding of the young; so that, out of all the various preceding divisions, individuals apparently arise which assist in the development of the more perfect progeny in the winter. There are in a hive of bees, individuals which are employed almost wholly in the feeding of the larvae (foragers), whilst others do scarcely anything else than collect wax and build cells (workers). In ant-hills, one set of the feeders is constantly employed in conveying the wax to the place to which the whole according to the Termites, the same thing occurs; the many thousand individuals which constitute one of these colonies are principally ‘feeders,’ or individuals which have originated in the preceding divisions of the eggs of the females, and in these is exhibited, even with greater precision, a more marked division of labour in the feeding of the young; so that, out of all the various preceding divisions, individuals apparently arise which assist in the development of the more perfect progeny in the winter. There are in a hive of bees, individuals which are employed almost wholly in the feeding of the larvae (foragers), whilst others do scarcely anything else than collect wax and build cells (workers). In ant-hills, one set of the feeders is constantly employed in conveying the wax to the place to which the whole according to the
slaughter, for which feast of arms the emperor gave him the command of the 11th corps. General Gérard was several times severely wounded, and he regarded the sole of his left foot as his "badge of honor." He died at Paris on October 18, 1813. During the defence of the French territory in 1814, his zeal and intrepidity were frequently commended by Napoleon, especially at the victory of Monte- beau. After his return from Elba, in 1815, the Emperor gave him the command of the French forces in the west. On the 18th of June he was under the orders of Marshal Grouchy at Wavres, and when the report of the cannon was heard proceeding from the forest of the Soignes, Gérard recommended an immediate advance of Grouchy's army of reserve upon Antwerp.

On the return of Louis XVIII., Gérard retired to Belgium, where in 1816 he married the daughter of General Valence. The following year he was permitted to return to Paris, where he was appointed brigadier-general. In 1821 he was appointed minister of war, and appointed him minister of war, but his health compelled him to resign this office a few months later. In 1832 he was sent to besiege the fortress of Antwerp, and a fleet of the Dutch General Chasse, when, having compelled the garrison to capitulate, after a gallant defence, he returned to France and was made a peer. In 1834 the citizen king made him president of the council, or prime minister; but his declining health obliged him to resign this office on the 23rd of October, 1834.

The provisional government of February 24, 1848, raised Marshal Gérard to the function of grand chamberlain of the Legion of Honour. The marshal lived to see the restoration of the Bonaparte dynasty. He died at Paris on February 17, 1852, and was interred in the chapel of the Invalides.

GERARD, JEAN-IGNACE-ISIDORE, but best known by his pseudonym, GRANDVILLE, one of the most eminent French caricaturists and designers of illustrations. He was born at Nancy, and went to Paris young, an adventurer without money, and without friends; after a while got admission to the stables of Lecomte; managed to subsist by designing costumes, &c.; and continued improving his artistic powers and increasing his stores of observation till 1829, when he brought out his "Metamorphoses du Jour," by Grandville, a series of grotesque, piquant, and mirthful crayon commentaries and criticisms on passing follies. These sketches had a prodigious success; Grandville's position was secured; and his pencil found abundant employment. The revolution of 1830 terminated his time for a time with his occupation; but when familiarity had brought its inseparable attendant, and the criticism that comes for the critic, that was a mark for the shafts of ridicule, Grandville made himself abundantly merry with the face and person of his sovereign and his royal advisers. Grandville was the very soul of "La Caricature," and his satire was equal to that which was before produced by the master himself on the fables of La Fontaine, &c.; but on the promulgation of the law re-establishing the "cenare préalable" for designs, he abandoned politics, and threw all his energy into the making of drawings on wood for illustrated editions of classic authors, &c. Here he found a new field of triumph. His drawings were in their way almost the perfection of designs for engraving on wood. Not merely were they admirably conceived, and excellent as exemplifications of the passages they were intended to illustrate, but clear, correct, and vigorous in drawing and brilliant in effect, they exhibited remarkable aptitude for that particular kind of engraving. As illustrations—full of fancy, ingenuity, quaint and genuine humor, and singularity suggestive—they not only pleased the eye, but really added new charm to the text. Among the works he illustrated were "Gulliver's Travels," "Robinson Crusoe," "La Fontaine's Fables," "Beranger," "Jerome Patolet," &c. Indefatigable in labour, he produced an almost infinite number of designs, and yet his active fancy showed no symptoms of exhaustion. He developed a method of distinguishing himself from other illustrators of books, by giving to each child within a brief space of time by some of the ordinary ills of childhood, when his third child in attempting to swallow a piece of meat got it so firmly fixed in its throat that all attempts to remove it proved unavailing. An inhalation was proposed as the only remaining chance, dangerous remedy; and while Grandville hesitated whether to
The surface of Iceland slopes gradually from the coast towards the centre, where the general level is about 3000 feet above the surface of the sea. On this, as a pedestal, we plant the Jokull’s, Icy Mountains of the region, which stretch out in a north-easterly direction. Along this chain the active volcanoes of the island are encountered, and in the same general direction the thermal springs occur, thus suggesting a common origin for them and the volcanoes. From the rivers and canals which diverge from the mountainous mighty mass of steam are observed to issue at intervals, hissing and roaring, and where the escape takes place at the mouth of a cavern, and the resonance of the cave lends its aid, the sound is like that of thunder. Local workers in a Supervolcanic zone. On these pools, where a repulsive blue-black aluminous paste is boiled, rising at times into huge billows, which on bursting scatter their slimy spray to a height of 15 or 20 feet. From the base of the water’s edge, a range of craters and fumaroles is visible. These are placed in the immense snow-fields which crown the summits. From the arches and fissures of the glaciers vast masses of water issue, falling in spouts in cascades over walls of ice, and spreading for miles and miles over the country before they find definite outlet. Extensive morasses are thus formed, which lend their comfortless monotony to the dismally scene already before the traveller’s eye. Intercepted by the cracks and fissures of the land a portion of these waters is conducted to the air’s open breast; others find their passage through the conic glasses which traverse these underground regions, both travel together, to issue at the first convenient opportunity either as an eruption of steam or as a boiling spring.

The origin of the water which feeds the springs is here hinted at. That origin is atmospheric. The summits of the Jokull arrest and mix the clouds, and thus cause an extraordinary deposition of snow and rain. This snow and rain constitute the source from which the springs are fed. The immediate cause, the aliment of the spring, is from the rains which fall like rain upon the surface of the ground, upon the soil, and every spring, exactly as we find them in rain water, furnish the proof of this; for the known deportment of these substances preclude them from being regarded as real volcanic products.

The springs which feed the Geysers, and which are poured out from them again boiling hot, probably take their rise in Mount Hecla, the summit of which is not more than 30 miles from the Geysier district. It is here that the rushing water is sometimes heard in chaona beneath the surface, and it has more than once happened that after earthquakes some of the boiling fountains have increased or diminished in violence and volume, or entirely ceased, or that new ones have made their appearance.

The phenomena of the Geysers of Iceland have for a length of time arrested the attention of naturalists, and many explanations of them have been given. No one has however so successfully investigated the subject as Professor Bunsen, of Gottingen. A summary of these views, with experimental illustrations, were presented to the Royal Institution by Professor Tyndall in June 1853. After referring to the general eruptive phenomena of Iceland, he described the Great Geyser.

"We have here," he says, "a tube 10 feet wide and 70 feet deep; it expands at its summit into a basin, which from north to south measures 52 feet across, and in the perpendicular direction 60 feet. The interior of the tube and basin is covered with beautiful white plaster and is designed to resist the blows of a hammer. The first question that presents itself is, how was this wonderful tube constructed? How was this perfect plaster laid on? A glance at the constitution of the geysier water will perhaps furnish the first surmise. In 1000 parts of the water the following constituents are found:

"The lining of the tube is silica, evidently derived from the water; and hence the conjecture may arise that the water deposited the substance against the sides of the tube and basin. But this outer deposit was burnt off, and the water boiled to a paste, cooled down to the freezing point. It may be bottled up and kept for years as clear as crystal, and without the slightest precipitate. A specimen brought from Iceland and analysed in this manner was perfectly free from sediment. Further, an attempt to ascertain the origin of this way would imply that we took it for granted that the shaft was made by some foreign agency, and that the spring merely lined it. A painting of the Geysier, the property of Sir Henry Holland himself, exhibits the features of these wonderful phenomena—was exhibited. The painting, from a sketch taken on the spot, might be relied on. We find here that the basin rests on the summit of a mound; this mound is about 40 feet in height, and a glance at it is sufficient to detect where the water has formed the system of the mound the spring must also have formed the tube which perforates the mound; and thus we learn that the Geysier is the architect of its own tube. If we place a quantity of the geyser water at an interesting height, it will take place—in the centre the fluid deposits nothing, but at the edges where it is drawn up the sides of the basin by capillary attraction, and thus subjected to a quick evaporation, we find silica deposited; round the edge we find a ring of silica thus held on, and not until the water has been evaporated for a considerable time do we find the slightest turbidity in the central portions of the water. This experiment is the microscopic representative, if the term be permitted, of nature itself. Imagine a simple thermal spring whose waters trickle over its side and down a gentle incline; the water thus exposed evaporates speedily, and silica is deposited. This deposit gradually elevates the side over which the water passes, until finally the latter has to choose another course; the same takes place here, the ground becomes elevated by the deposit as before, and the spring has to go forward—thus it is compelled to travel round and round, discharging its silica and deepening the shaft in which it dwells, until finally, in the course of centuries, a colossal column of water is produced, and the Geysier a stately cataract which has so long puzzled and astonished both the traveller and the philosopher.

"Before an eruption the water fills both the tube and basin, dotating filled; and when this stimation a violent ebullition in the basin is observed; the column of water in the pipe appears to be lifted up, forming a conical eminence in the centre of the basin, and causing the water to flow over its rim. The detonations are evidently due to the production of steam in the subterranean depths, which, rising into the cooler water of the tube, becomes condensed and produces explosions similar to those produced on a small scale when a flask of water is heated to boiling. Between the interval of two eruptions the temperature of the water in the tube towards the centre and bottom gradually increases. Bunsen succeeded in determining its temperature a few minutes before a great eruption took place; and these observations furnished to his clear intellect the key of the entire enigma. A little below the place where the water was within two degrees of its boiling point, that is, within two degrees of the point at which water boils under a pressure equal to that of an atmosphere, plus the pressure of the superincumbent column of water. The actual temperature at 30 feet of this point was 195°. Of course, its boiling point here is 134°. We have just alluded to the detonations and the lifting of the geyser column by the entrance of steam from beneath. These detonations and the temperature of the water, in the course of these intervals, have been heard and observed at various intervals before an eruption. During these intervals the temperature of the water is gradually rising. Let us see what must take place when its temperature is near the boiling point. Imagine the section of water at 30 feet above the bottom to be raised six feet by the generation of a mass of vapour below. The liquid spreads out in the
basin, overflows its rim, and thus the elevated section has six feet of water pressure upon it; its boiling point under this diminished pressure is 121°; hence in its new position its actual temperature (129°) is a degree above the boiling point. This excess is at once applied to the generation of steam; the column is lifted higher, and its pressure further lessened. Steam is developed underneath; and thus, after a few convulsive efforts, the water is ejected with immense velocity, and we have the geyser eruption in all its grandeur. By its contact with the atmosphere the water is cooled, falls back into the basin, sinks into the tube through which it has ascended, and thus the basin is replenished.

The detonations are heard at intervals, and ebulitions are observed; but not until the temperature of the water in the tube has once more nearly attained its boiling point is the lifting of the column able to produce an eruption.

"In the regularly-formed tube the water nowhere quite attains the boiling point. In the canals which feed the tube, the steam which causes the detonation and lifting of the column must therefore be formed. These canals are in fact nothing more than the irregular continuation of the tube itself. The tube is therefore the sole sufficient cause of the eruptions. Its sufficiency was experimentally shown during the eruption of a geyser of galvanised iron six feet long was surmounted by a spring in a small underground chamber and one near its centre to imitate the lateral heating of the geyser tube. At intervals of five or six minutes throughout the lecture eruptions took place; the water was discharged into the void back into the tube, became heated, and was discharged as before."  

Sir George MacKenzie, it was well known, was the first to introduce the idea of a subterranean cavern to account for the phenomena of the Geyser. His hypothesis met with general acceptance, and it was endeavoured to obtain some of those who accompanied Bunsen to Iceland. It is unnecessary to introduce the solid objections which might be urged against this hypothesis, for the tube being proved sufficient, the whole of the subterranean cavern disappears with the necessity which gave it birth.

"From the central portions of the geyser tube downwards, the water has stored up an amount of heat capable, when liberated, of exerting an immense mechanical force. By an easy calculation it might be shown that the heat thus stored up could generate, under ordinary atmospheric pressure, a column of steam having a section equal to that of the tube and a height of nearly 1300 yards. This enormous force is brought into action by the lifting of the column and the lessening of the pressure described above.

"A moment's reflection will suggest to us that there must be a limit to the operations of the Geyser. When the tube has reached such an altitude that the water in the depths below is so compressed that the pressure at the boiling point, the eruptions of necessity cease. The spring however continues to deposit its silica and forms a 'fang,' or cistern. Some of these in Iceland are of a depth of 30 or 40 feet. This is indescribable; over the surface a light vapour curis. In the depths the water is of the purest, azur, and tints with its own has the fantastic incarnations on the cistern walls; while at the bottom is observed the mouth of the once mighty Geyser. There are in Iceland traces of vast, but now extinct, geyser operations. Mounds are observed whose shafts are filled with rubbish, the shafts having forced a way underneath, and retired to other scenes of action. We have in fact the Geyser in its youth, manhood, old age, and death, here presented to us;—in its youth as a simple thermal spring; in its manhood as a fully developed persistent eruption; in its old age as the tranquil lung; while its death is recorded by the ruined shaft and mound, which testify the fact of its once active existence.

"Next to the Great Geyser the Strokkur is the most famous eruptive spring of Iceland. The depth of its tube in 44 feet. It is not however cylindrical like that of the Geyser, but funnel-shaped. At the mouth it is 8 feet in diameter, but it diminishes gradually, until near the centre the diameter is only about a foot. Water is continually fed into the tube and thus stopping it, eruptions can be forced which in proportion of height often exceed those of the Great Geyser. Its action was illustrated experimentally in the lecture, by stopping the great tube before alluded to loosely with a cork. After some time the water, by the increase of heat converting itself suddenly into steam, the water was ejected to a considerable height—thus demonstrating that in this case the tube alone is the sufficient cause of the phenomenon." ('Proceedings of Royal Institution.')

The results of the researches of Professor Bunsen on the Geysers of Iceland seem to throw great and unexpected light on the phenomena of volcanoes. Sir Charles Lyell notices his account of Bunsen's researches with the following remark: "In speculating therefore on the mechanism of an ordinary volcanic eruption, we may suppose that large subterranean cavities exist at the depth of some miles below the surface of the earth, and that a fluidified lava is contained in the cavity. Water and the usual mixture of air penetrates into these, the steam thus generated may press upon the lava and force it up the duct of a volcano, in the same manner as a column of water is driven up the pipe of a Geyser. In other cases an eruptive column may consist of a continuous mixture of water, red-hot water (for water may exist in that state, as Professor Bunsen reminds us, under pressure), and this column may have a temperature regularly increasing downwards. A disturbance of equilibrium may first bring on an eruption near the surface, by the expansion and conversion into gas of entangled water and other constituents of what we call lava, so as to occasion a diminution of pressure. More steam would then be liberated, carrying up with it jets of molten lava; and the hot water, being higher in temperature, would fall in layers of ashes on the surrounding country, and at length, by the arrival of lava and water more and more heated at the orifice of the duct, or the crater of the volcano, expansive power may be acquired sufficient to expel a massive current of water and lower heated lava, by a series of regular eruptions of quasi-liquids, during which fresh accessions of heat are communicated from below, and additional masses of rock fused by degrees, while at the same time atmospheric or subterranean water is descending from the surface. At length the conical mass is elevated to such an extent that a new cycle of similar changes is renewed." (Principles of Geology, p. 558.)

GIANTHOLITHS. [MINERALOGY, &c.] By the Rev. Mr. M'Mahon, M.R.C.S.  

GILT-HEAD. [CHIRURGY; CARNIVORA.]  

GILOBERTI, VINCENTO, born on the 5th of April 1801, in the city of Torino (Turin), the capital of the kingdom of Sardinia. He studied with a view to the ecclesiastical profession, and having completed his education in the University of Turin, received the degree of Doctor of Theology, and became one of the teachers in the theological college.

Soon after the accession, in 1831, of Charles-Albert to the throne of Sardinia, Giberti was appointed chaplain to the court. In 1832 he performed the office till 1833, when, on some accusation or suspicion of being implicated in the political agitations then prevailing in various parts of Italy, he was suddenly seized in the apartments which he occupied in the palace. For some time he was kept in prison. There he was detained for about two weeks, but was at length set at liberty on the condition that he quitted the country as an exile. He went to Paris, where he resided till the end of 1836, when he removed to Brussels, having accepted the offer of a situation as teacher in one of the public schools of that city.  

Gioberti wrote at Brussels, during his long abode there as an exile, nearly all those works which not only extended his literary reputation throughout the whole of Europe, but produced that enthusiasm of admiration which was displayed by the Italians after his return to his native country. The first of these works was the "Teoria del Sovranatural," one Dicono sulle Convenienze della Religione Rivelata alla Mente Umana e col Progresso Civile delle Nazioni," 1837. His "Introduzione alla storia del cristianesimo" in "Il glossario Italiano," 1840, was followed by the "Lettere intorno agli Errore Filosofici di Antonio Romagni," 3 vols., 1841-43, and the two treatises "Del bello," 1840, and "Del bello," 1843. His "Primo Morale e Civile degli Italiani," 1843, was read with eagerness by all the Italian public, and excited expectations of the regeneration of that unfortunate country, which, with the sole exception of the Sardinian kingdom, had not hitherto been realized. There was to be a confederation of the Italian states, in which the Roman Church was to be the head, and the Pope, as monarchs and Jesuits, were all to bear a part. The states were to be reformed, and public rights and privileges gradually established. The pope was to be the head of the Roman Church, and not of the state; the King of Sardinia was to be the military chief of Turin and the grand citadel. The Jesuits alone were dissatisfied, and Gioberti
attached them in his 'Prolegomeni,' 8vo, 1848. Plus IX
on his accession to the post of a prior in 1846, adopted the views
of Gioberti, and began to carry out the reforms recommended in
'Il Primauro; and as the opposition of the Jesuits still con-
tinued, Gioberti produced his great attack on their principles and
practices, under the title of 'Il Gesuita Moderno,' 5 vols.
8vo, 1848.

When the French revolution of February 1848, occurred,
Gioberti was at Paris occupied with his plans for the renova-
tion of Italy. On the 20th of April he quitted Paris, after
an exile of fifteen years, to return to his native city of Turin,
where his arrival was welcomed with universal enthusiasm by
day, and illuminations and fireworks at night, accompanied
with music and dancing and patriotic songs; and afterwards
when he passed through Milan, Genoa, Florence, Rome, and
other cities, he was received with the greatest enthusiasm,
so that his return resembled a triumphal pro-
cession. On his return to Turin he was elected a member
of the chamber of deputies, of which he was unanimously
chosen president. He was opposed to all violent reforms, but the
idea of political excitement in the year 1848 threw him into
the ranks of the opposition, and on the 16th of December the
king appointed him the prime minister of a democratic
cabinet. He soon found himself to be in a false position;
and his diagnosis of the present and future of his colleagues led to a dissolution of the ministry on the 15th of
February 1849. He was succeeded by Pinelli, and soon after-
wards was sent to Paris to solicit aid from the French govern-
ment in the approaching conflict with Austria. His mission
was unsuccessful. Charles-Albert defeated at Novara, and Victor-Emmanuel II. has
alone, of all the rulers of Italy, preserved for his subjects
a constitutional government, a free press, and a just adminis-
tration of the laws. Gioberti returned in Paris, and the fruit of his renewed labours was published in the 'Civiltà d'Italia,' 2 vols. 8vo, 1861. He died October 26, 1862,
in Paris.

GIRARDIN, MADAME DELPHINE DE, the wife of
Émile Girardin, and daughter of Sophie and Antoine de Mad
difique, was born on the 27th of August, 1805, at Aix-la-Chapelle.
She was what is called a precocious genius, and at the age of
fourteen was noted for her remarkable beauty. In 1823 a
poetical elegy of hers, containing all the illustrious names of the
day, was honourably mentioned by the French Academy.
On the 26th of April, 1837, she was received with great pomp
in the Capitol of Rome by the Académie de Titre, as one of
their members. She received a more flattering ovation in
Paris, on her return. The artist Lagre, who had recently
married her, prepared a large history painting, of which
Madèle. Delphine Gay to a place of honour beneath the dome,
where she recited some of her own poems in the presence of
a brilliant assembly. As soon as she finished a shower of
flowers and roses was thrown upon the stage. King Louis
X. ended her elopement of 1500 francs from her private
purse. Shortly after, she met with M. Émile de Girardin, to
whom she was married in 1831.

Immediately after this union Madame Girardin engaged in
a variety of literary undertakings, producing novels,
romances, and fugitive poems for the book-sellers; tragedies,
comedies, and vaudevilles for the theatres; and feuilletons
for the newspapers. Her charming 'Lettres Parisiennes' appeared in
the journal 'La Presse,' under the name of Vincente C. de Lancy. She occupied with her husband at Chailot was the resort of all the célèbres
in art and literature, as well as of the élite of the Beau Monde.
Every intelligent foreigner desirous of seeing the eminent and
distingushed personages, which swarmed at her house, hastened
to this house, built on the model of the Great
temples.

This clever authoress died on the 29th of June, 1855,
and on the 5th of July she was followed to the grave by an
innumerable crowd. The chief funeral oration was delivered by
Jules Janin.

The catalogue of her works is very long; but the following
are her most esteemed productions:—'Le Pélican,' published in
1833; 'Le Lorgeron,' a romance, 1839; 'Que se sont
Céleste et Clémente,' a romance, 1834; 'Le Canne de M. de Balaize,' 1836; 'L'Ecole des
Journalistes,' a five-act comedy, 1840; 'Judith,' a tragedy,
1843; 'Cléopatre,' a tragedy, 1847; 'Lady Tartufie,' a
three-act comedy; 'Produced much success,' 1845; and 'La June
Fait Pouer,' 1844.

GLADIOLUS, Cuss-Flag (from 'gladius,' a sword, refer-
ring to the shape of the leaves), a genus of plants belonging to
the natural order Fruebeae. It has a tubular 2-lipped corolla;
seeds with a testa; and seeds with an arilus; root a coated bulb; leaves ensiform,
arrow. The species in the gardens are bulbous, and are
chiefly brought from the Cape of Good Hope.

G. florivorus, 2 or 3 flowers, 2-3 furrows. The upper
division of the corolla is denerate, the lower segment near
ly equal and lanceolate; anthers longer than the filaments;
capsules with 3 furrows. It has been supposed to be an
aphrodias, a reputation obtained from its acrid qualities,
which were supposed to make it poisonous. A certain
Hotentot eats the tubers or corms of several species of this genus, the starchy
containing them nutritious.

G. triphyllum has about 3 flowers in one row; the anthers
much shorter than the filaments. It is found in the moun-
tains of Carrara.

G. palustris has 3 or 4 flowers, 2-3 furrows; the tube twice
as long as the seed-veil; the claw of the middle division
curved and renate; the lobes of the stigma papillosus-ciliate
almost from the base; anthers shorter than the filaments;
seeds at the base obtuse, parallel; capsules oblong,
obovate, rounded at the top, marked with six equal furrows.
It is found in Germany.

G. semiovatus has second flowers; the filaments half as
long again as the anthers; anthers at the base obtuse and
parallel; the tube half as long as the anther; the stigma gently broader upwards, papillosus-ciliate
almost from the base; capsules 3-edged, obovate, impressed
at the top, toothed, or winged. It is found near Stettin and Frankfurt-am-Oder.

G. Illyricus has second flowers; the tube three times as
long as the anther; the division of the stigma linear from the
base to the middle, and with a smooth margin suddenly enlarged
at the top with a papillosus ciliate margin; the capsules
obovate, 3-edged. A native of Illyria.

G. imbricatus has second approximate flowers; the tube
nearly three times as long as the anther; the division of
the stigma gradually broader upwards, papillosus-ciliate
almost from the base; the capsules have 5 or 6 rows with 3 rounded angles. Found
in Bohemia and Slavonia.

G. infestus has a lax spike; flowers 4 to 14, obliquely
alternate; division of corolla alternately pink and purple,
uppermost very broad, covering the 3 internal ones, the
lower unequal; anthers about as long as the filaments;
seeds globose, prolonged downwards. It is a native of Sicily.

G. Byzantinus has numerous flowers in two rows; the upper
segment of the corolla covered by the lateral ones;
the lower divisions of the stamens the longest; the anthers
longer than the filaments; seeds winged; leaves long,
ensiform, and linear. Found in Sicily.

GLAND, a term applied to cells and collections of cells in
the animal body, which have the power of absorbing or sepa-
rating the parts of substances which are separated from the
blood the peculiar substances of which they are composed.
The term gland however is only strictly applied to those
forms of tissues which separate peculiar matters. "A true
gland," says Dr. Carpenter, "may be said to consist of a
closely packed collection of follicles, all of which open into
a common channel, by which the product of the glandular
action is collected and delivered. The follicles contain the
secreting cells in their cavities, whilst their exterior is in
contact with a network of blood-vessels from which the
cells draw the materials of their growth and development."

In a wide sense the term gland has been applied to those
parts of the body which excrete or absorb the food or carrying to the blood the materials of used-up
substances. [Amaurosis.] In all cases the cell is an active
agent whether of absorption or secretion. The agency of
the cell in the blood is about 10 by 19, in the way in which
the chyle is taken from the intestines and carried into the lacteals.

For further investigations on the structure of Glands, see
Tessier, Osmaju, S. 1, pp. 643, 644, 644. After describing the
development of glandular tissue, Professor Goodir
wrote, 'The emphasis on this subject is determined with the following
marks:—

"It appears to be highly probable therefore that a gland
is originally a mass of dissociated cells, the progeny of one or
more parents, and connected by no relation whatever with the
embryo gland may or may not, according to the case, send
a portion of the membranes in the form of a hollow cone

2 N 3
into the mass: but whether this happens or not, the extremities of the ducts are formed as closed vessels, such as are formed at the extreme or oral end of the parents of the epithelium cells of the perfect organ. Dr. Allen Thomson has ascertained that the follicles of the stomach and large intestines are originally closed vessels. This would appear to be the normal form of a follicle, and the source of the germinal spot, which plays so important a part in its future actions.

The ducts of glands are therefore intercellular passages. This is an important consideration, inasmuch as it ranges the cell-cavity with the intercellular passages and secreting receptacles of vegetables.

"Since the publication of my paper on the secreting structures, in the 'Transactions of the Royal Society of Edinburgh,' in 1842, I have satisfied myself that I was in error in supposing that the cavity of the cell-wall was the cell-cavity. The nucleus is the part which effects this. The secretion contained in the cavity of the cell appears to be the product of the solution of successive developments of the nucleus, which in some instances contains in its component vessels the peculiar secretion, as in the bile-cells of certain Moluscos; and in others develops into the secretion itself, as in seminal cells. In every instance the nucleus of each cell surrounds the secretion contained in the cell-wall, and in the cavity of which the secretion is cast. This accords with that most important observation of Dr. Martin Barry on the function of the nucleus in cellular development. I have also had an opportunity of seeing a secretion cast in a cell by experiment, at the time fully anticipated—the remarkable vital properties of the third order of secretion referred to in the memoir to which I have just alluded. The distinctive character of secretion of the third order is, that when thrown into the cavity of the gland they consist of entire cells, instead of being the result of partial or entire dissolution of the secreting cells. It is the most remarkable peculiarity of this order of secretions, that after the secreting cells have been thrown out of the gland cavity, and the cavity, and therefore no longer a component part of the organism, they retain so much individuality of life as to proceed in their development to a greater or less extent in their course along the canal or duct before they arrive at their full extent of elimination. The most remarkable instance of this peculiarity of secretions of this order is that discovered by my brother. He has observed that the seminal secretion of the decapod crustacea undergoes successive developments, the solution of the secreting cells, and the duct---but only becomes developed into spermatogonia after coitus, and in the spermatheca of the female. He has also ascertained that, apparently for the nourishment of the component cells of a secretion of this kind, a quantity of albuminous matter floats apparently separately from which the gland cells are developed after separation from the walls of the gland. This albuminous matter he compares to the substance which, according to Dr. Martin Barry's researches, results from the solution of certain cells of a brood, and affords nourishment to their survivors. It is one of other instances in which cell do not derive their nourishment from the blood but from parts in their neighbourhood which have undergone solution, and it involves a principle which serves to explain many processes in health and disease.

"I conclude therefore, from the observations which I have made, that all the true secretions are formed or secreted by a vital action of the nucleated cell, and that they are thrown out of the cavity of that cell; and, that growth and secretion are identical—the same vital process under different circumstances."

Having thus examined the nature of the process by which the cell secretes, we may now refer to some of the more prominent modifications of the organs called glands. The simplest condition of a Gland is the simple inversion of a secreting membrane called a follicle. These occur in the skin, as in the sebaceous follicles, and also in the mucous membrane of the stomach, where they are called gastric follicles. In these cases the follicle is in the membrane covered with secreting cells. In the early stages of the development of all glands we have this simple condition, and in the permanent condition of the more complicated glands, we have a modification of the lower, by which we have the same simple development. Thus the liver is some of the Polypes and lower Moluscos consists merely of a series of separate follicles placed in the walls of the stomach. The chick was first in the egg presents the same condition of this organ.

The Gland and Glandular in the commencement of the development of a mammatory gland in the Mammalia. In the Ornithorhynchus this organ consists of a mere cluster of blind sacs. In the same way in many fishes the pancreas begins its existence as a mere group of blind follicles. The next stage in the complexity of a gland is where a number of follicles open into a single tube. Such a condition of the gland is seen in what are called the Melobian glands of the eye. The larger glands of the body, as the pancreas, liver, and salivary glands, are merely variations of this process. Innumerable follicles empty themselves into tubes which again empty themselves into other tubes until the whole contents of the gland are thrown out from some common opening.

GLOMEROUS TUBULES. [LINCOLNSHIRE.]

GLAUCINE [CHEMISTRY, S. 2.]

GLAUCOIDE [MILLER, B. M.]

GLANCOLIC [MILLER, B. M.]

GLECHOMA [MAFFTA, S. I.]

GLEICHNIA [CHEMISTRY, S. 1.]

GLOBE-FISH [TETRADON]

GLOBE-FISH [TETRADON]

GLOBE-PLUMER [TROLLIUS]

GLOBULAR [TROLLIUS, S. I.]

GLOCOCLADEIA, a sub-order of Sea-Weeds belonging to the natural order Cryptocificaceae. The fronds are loosely gelatinous, the filaments of which are composed lying apart from one another, surrounded by a copious gelatine. The faldellas are immersed among the filaments of the periphery. It embraces the following genera:

Corallina.—Fong crustacea, skin-like.

Nemalia.—Fong frilliam, solid, cellular; the ramuli only covered with the frilliam.

Glosochloris.—Fong tubular, hollow, the walls of the tube composed of radiating filaments.

Nemalia.—Fong frilliam, solid, elastic, filamentosus; the axis composed of closely packed filaments, the periphery of monozone, the monofilar, and monostriatum.

Dendroclades.—Fong frilliam, solid, gelatinous, filamentous, the axis composed of a net-work of annostomising filaments; the periphery of moniform free filaments.

Glosochloris.—Frilliam frilliam, consisting of a pointed filament, whorled at the points, with minute mucilegous gelatinous ramuli.

(Harvey, British Sea-Weeds.)

GLOSSOPHARYNGEAL DENTAL UNION, a manufactory and the seat of a Poor-Law Union in the parish of Glossop, is situated on elevated ground rising from a deep valley near the north-western boundary of the county, in 54° 26' N. lat., 1° 55' W. long.; distant 49 miles N.W. by N. from Derby, 176 miles N.W. by N. from London by road, and 193 miles by the Manchester and Sheffield and Manchester and Huddersfield railways. The population of the township of Glossop in 1851 was 5467; that of the entire parish, which contains 49,960 acres, and is the most extensive in the county, and one of the most extensive in the district, was 36,685. The living is a vicarage in the archdeaconry of Derby and deanery of Lichfield. Glossop Poor-law Union contains 10 townships and hamlets, forming a part of Glossop parish, with an area of 30,807 acres and a population in 1851 of 19,860. The Poor-law Union, besides the parish, includes Glossop, High Glossop, and Ashopton, and the townships of Hopwood, Hollinswood, and Hollinwood, with the manorial and other lands of the inhabitants. About 60 cotton-mills are in the town and neighbourhood; there are also silk-worms, paper-mills, iron-foundries, dye-works, and bleach-fields. Besides the parish church, there are chapels for Independents and other Dissenters. A charity for
closely 34 poor men and women was founded by Joseph Hague, Esq. There is a savings bank. Melandra Castle, situated near the Armadillos, is the site of the Roman station; the works appear to have been nearly square, 366 feet by 336 feet; the ramparts, parts of the ditch, and other portions may be distinguished. A Roman road called the Doctor's Gate runs from Melandra Castle to Brough.

GLOSSOPORIS, a genus of Animals belonging to the order Amelida, and placed commonly near the Leeches. It has a posterior disc, but it is not ascorial. GLOSSOPODIUM, [Chemistry, S. 1;] TIMBER, ORGANIC, S. 1.] GLYCERIN, a genus of Desirobrecta Amelida. It is distinguished by the form of its head, which terminates in a conical, fleshy horn-like point, which is divided at the top into two, with a denticle on each side. GLYCERYL. [Chemistry, S. 2.] GLYCOCINE. [Chemistry, S. 2.] GLYPSODON, a genus of Acanthopterygian Fishes belonging to the family Scincidae. The gill-covers are entire, and they have a single row of tranchant and sometimes toothed teeth. The species are found in the Atlantic, but are more abundant in the Indian Seas.

GLYPTODON (Owen, so named from the fluted character of the teeth) belongs to the order Edentata, and allied in form and structure to the modern Armadillos. The first notice of the discovery of the remains of the skeleton of a large edentate animal, with fragments of a tesselated bony armor, similar to that of the Armadillos, was given by Cuvier, in 1822, in his description of the Glossopondon, in his chapter on the Megatherium, in the 4th edition of the 'Oeconomie Fossiles,' published in 1812. This notice occurs in an extract from a letter addressed by D. Danilois Larramde, curator of the Museum of History, to the Auguste St-Hilaire, which is published in the 'Mons. de l'Acad. des Sci. de Paris,' in 1832. A femur was discovered in the Rio del Lanco, branch of the Napoles Grande, which weighed 7lbs.; it was short, but might be from 6 to 8 inches in width; it resembled in every respect the femur of one of the large species of Glossopondon, and bore the peculiarities of the bony armor, of which the curé promises to send one of the component pieces to M. Auguste Geoffroy. The tail was very short and very stout; it had in like manner a bony armor, but this was not verticillate or disposed in rings. These fossils were stated to have been met with near the surface of the earth, in cultivation or strata of transport, indicative of a very recent epoch. Similar fossils are said to occur in analogous strata near the Lake Nirum, on the front of the Foemines, and in small tentacles.

These remains were supposed to belong to the Megatheriidae, and Cuvier does not appear to suspect that they belonged to anything else, as he merely remarks that the Megatheriidae had pushed its analogies with the Armadillos so far that they might be identified with these.

Subsequently remains of this kind were sent to England, and in the meantime M. Lavoisier and Mr. Pentland, on comparing these with those originally sent to England, came to the conclusion that they belonged to the genus Glyptodon. This however was doubted by Mr. Cliff and Professor Owen, seeing that the confirmation of the alveoli of the jaw indicated a dentition differing more widely from that of the existing sub-genera of Armadillos than their respective dental characters differ from one another. "It was at this conjecture," says Professor Owen, "that Sir Woodbine Parish received the intelligence of the discovery of an entire skeleton, covered with its tesselated coat of mail, about 5 feet below the surface, in the bank of a rivulet near the Rio Mancas, about 20 miles south of the city of Buenos Ayres, and with the account of this remarkable discovery there was at the same time transmitted a drawing or sketch of the whole animal, which has since been lithographed, and one of the teeth of the fossil itself. This tooth Sir Woodbine Parish states is exactly like that in my example of the same species; the structure proved it to belong to an animal referrible to the Edentata of Cuvier; but its character was so peculiar that I had no hesitation in pronouncing it to differ from that of any known edentate. I do not propose to assert so new and important a discovery as that of a new genus of the Armadillo family, for which I proposed the name of Glyptodon, in reference to the plated or sculptured character of the tooth."

The Glyptodon differs from the Megatherium not only in the form and structure but in the number of its teeth, which appear to be eight on each side of each jaw, as in the section of Armadillos called Cacochomus by Cuvier. It differs from the section of the species of that animal, and appears to be the result of a long process descending from the sygno, in both which respects it resembles, and evidently indicates a transition to the Megatherium.

Numerous and of this curious and interesting animal have been found in various parts of the country, and a very fine specimen, with the coat of mail almost entire, is to be seen in the museum of the College of Surgeons. Portions of this animal are also to be seen in the collection of the British Museum, S. 4.

Although, when the remains of the Glyptodon were first brought to Europe, it was not thought improbable that the Megatherium also was enclosed in a gigantic suit of armor, no remains that could be regarded as the tesserae of such a covering has been discovered. It is always difficult, however, to establish a negative, but the following arguments have been adduced by Professor Owen against this supposition, and will be probably regarded by most naturalists as conclusive:

1. The opinion of Cuvier and Weiss, in favour of the Megatherium being so armed, rests on no better ground than the mere fact of bony armor of some gigantic quadruped and the skeleton of the Megatherium having been discovered on the same level. 2. The skeleton, or its parts which have been actually associated with the bony armor above mentioned, belongs to a different and smaller quadruped. 3. No part of the skeleton of the Megatherium presents those modifications which are related to the support of a bony dermal covering. 4. The proportions of the component tessera of the bony armor in question to the skeleton of the Glyptodon, are the same as those of the bony armor and skeleton of existing Armadillos, but are vastly smaller as compared with the bones of the Megatherium. 5. No bony armor composed of tesserae, having the same relative size to the bones of the skeleton of the Megatherium, as the Glyptodon and existing Armadillos, has yet been discovered. 6. The skeleton of the Megatherium has never been found associated with bony armor of any kind, neither have its parts been found associated."

(Owen, Proceedings of Geological Society, vol. vii., 2nd series.)

GMELIN, LEOPOLD, was born at Göttingen on the 2nd of August, 1783. This eminent chemist and contributor to the literature of the sciences of which he was an equally eminent academic teacher, began for four generations had been actively engaged in the pursuit of chemistry, the medical sciences, and several branches of natural history, and one member of which, if not more, is still of his great devoted himself to this science. He became professor of chemistry at Göttingen, was the father of the distinguished man we have now to commemorate.

Leopold Gmelin, from 1799 to 1804 attended the Lyceum in that city, and in the summer of 1804, his father's death removed him to Tübingen, where he practised chemical manipulation in the pharmaceutical laboratory of his near relation, Dr. Christian Gmelin (the son of Johann Conrad Gmelin and father of Christian Gottlob Gmelin, both already mentioned), and attended Kuhlmeier's lectures. In the autumn of 1800 he returned to Göttingen, where he devoted himself with zeal to all branches of medical science, but especially to chemistry, for which he attended Strömeyer's lectures; he also studied mathematics. After passing a distinguished examination, he went, in the summer of 1809,
known facts of the sciences are condensed into the smallest possible space, but nevertheless it presents a complete picture of the development of the sciences and the contributions of other chemists were often indebted to the author for first giving them their true value. In this great work, to use the words adopted, in 1804, by the President of the Chemical Society of London, of which Gmelin was a foreign member, "the labours, the advice and the discoveries of an infatuated but objectivistic, and on the authority of the several investigations, all that has been observed within the domain of chemistry, —not, indeed, withholding his own opinions, but placing himself side by side with those of others, and never suppressing the latter."

The 'Handbook of Chemistry,' moreover, has often directed attention to deficiencies and contradictions in existing chemical knowledge, and has thus given rise to new investigations. It is a work of profound and vast extent, giving an accurate knowledge of chemistry, not only in Germany, but wherever the science is cultivated. The first edition, which appeared in the years 1817-1819, included in a comparatively small space the extent of chemical sciences then known; the fourth, which had just been prepared by Gmelin himself, was published from 1843 to 1853, and comprehends inorganic chemistry, but, unfortunately, only a small part of organic chemistry. From this the English edition, now in course of preparation, of the Transactions of the Cavendish Society, is translated by Mr. Henry Watts, B.A., Fellow of the Chemical Society of London, of whose 'Quarterly Journal' he is also the editor. The additions made by him bring the 'Handbook' down to the existing state of chemical science.

In the 'Annals of Philosophy' for August and September 1821 there is an account of Gmelin's 'Handbook,' that he became quite neglectful of his health. In 1846, he had an attack of paralysis, which, though it only deprived him for a while of his power of action, destroyed the freshness and vigour of his manner, and elasticity of speech. He still worked at his 'Handbook' with untiring assiduity, and the work was published in 1850. In 1852, he was again attacked by paralysis, which obliged him to resign his professorial functions. He still however remained active in the cause of science, and laboured on the second edition of the 'Organic Chemistry,' which he completed in May, 1852. But from that time his powers, both mental and bodily, rapidly declined; an insidious disease of the brain was steadily gaining ground. In the spring of 1853 it became evident that his end was approaching, and he died on the 19th of April, in the sixty-fifth year of his age.

Leopold Gmelin's original researches in chemistry are numerous; they are all of high character, and as complete as the means of investigation existing at the time when they were undertaken. In 1800 he undertook, in conjunction with Tiedemann, a series of experiments on digestion; and in 1808 and 1809 these two philosophers published their celebrated work, entitled 'Die Verdauung nach Vorontsen,' and he devoted himself to the science, —"a service in which," in the words of competent authority, "he surpassed all his predecessors and all his contemporaries"—committed in the production of his 'Handbook of Chemistry,' the beginning and later progress of which have been described. After the death of his son, F.R.S., afterwards Regius Professor of Chemistry in the University of Glasgow, he published the earlier editions of his 'System of Chemistry,' in which he reduced to order, in a clear and comprehensible system, the facts of science, scattered at the time he wrote over a thousand different veins of knowledge, and had thus himself conferred an inestimable benefit, especially on British chemists; other writers also had arranged large quantities of materials in systematic order; but for completeness and facility of collation, and consecutiveness of arrangement, Gmelin's 'Handbook' is unrivalled. In it the
own productions, and it is said that in composing a dialogue, it was his practice to recite all the different speeches in character before committing them to paper, by means of which he ascertained more satisfactorily if they were in complete consonance with what the character and situation required. His soon tried his powers in the drama, and his comedy of "The Tsar's Servant," which was surprisingly successful, but its success was due to a peculation and misconduct among all the government officials, that when he is at last discovered they are glad to let him off scot free and hush up the whole affair. The Emperor Nicholas I, who had not seen the play, was greatly pleased with its marked applause. It was however chiefly popular among the Russian liberal party, who affixed to it a deeper significance than to a foreigner appears altogether just, and considered it an open and serious attack on the institutions of Russia in general. That it was not looked upon in this light by the government seems sufficiently proved by the appointment of Gogol as professor of history at the University of St. Petersburg, where it was his intention to devote himself to more serious studies. His next work however was his famous novel, the "Dead Souls" ("Pokhodnymiia, Chigachova, Ila Mervtviia Dushi"), published at Moscow in 1842. The English public has an opportunity of forming an estimate of this, the principal work of Gogol's, in a passage in the "Periplus," in which Gogol had appeared to speak with personal conviction on this subject. He says that he had not the courage to say that he did not share the opinion of their admirers. "These persons," says Bielineski, "may in their admiration of you have made more notes with their applause than the case required; but after all, their enthusiasm sprang from so pure and noble a source that it was only sincere, and it behooves us not only to print new sketches of life, but not even two lines on the subject till I have returned to Russia, have seen it with my own eyes, and touched it with my own hands." Neither Bielineski nor Gogol ever returned. Bielineski died in France of the plague after the appearance of this passage in the "Periplus." The book may be suspected of having its origin partly in political feelings.

Soon after the appearance of the book which raised his fame to its highest point, the author, whose health was bad, obtained a pension and retired to his native city of St. Petersburg. He was honored by a visit from the son of the time of the publication of "Select Passages from N. Gogol's Correspondence with his Friends" ("Vubranovnya Miestia is Perepiiska s Druznami"). St. Petersburg, 1847. St. Petersburg, 1847. From the height of popularity this publication sank at once to the lowest depths of contempt. His liberal friends found with surprise that the satirist of Russia, when at home, had become the panegyrist of Russia, autocracy and all, who beyond the frontier. Bielineski, who was one of the principal, attacked in so far as the "Sovereigns," one of the leading reviewed in St. Petersburg, in an article which could hardly have been expected to pass the censorship. Gogol addressed to him a letter of remonstrance, protesting that the change which had taken place in his opinions was the result of conviction, and the reflection of the "Sovereigns." In a letter to "Zriiiza," or "Polar Star," a Russian periodical issued in London in 1855. "Yes," says Bielineski, "I loved you with all the passion with which a man warmly attached to his country, can be found, and I love the great leaders in the path of self-consciousness, development, and progress. You had good cause indeed to be shaken out of your repose of soul, for a minute at least, when you lost the right to such love as this. I do not speak thus because I consider any feelings of mine an adequate recompense for such genius as yours, but because in this respect I do not stand alone, but represent a multitude of whom neither you nor I have ever seen a single majority, and only a few whom you and I alone love. You," he afterwards broke out, "you, the author of the Revisor and the Dead Souls,—can you, sincerely, and from your soul, raise a hymn of praise to the disgusting Russian clergy, placing it unmistakably above the clergy of the Roman Catholic Church, do not you think that the latter was sometimes something, while the former was never nothing but the lackey and slave of the secular power; but is it possible you do not know that our clergy stands in the lowest degree of contempt with Russian society and the Russian people, and that every Russian, every Russian the representative of glutony, meanness, servility, impudence? I will not dilate on your dilthrambolies about the bond of affection between the Russian clergy and the people, which I have already refuted. What I have met with so much sympathy, and has lowered you even in the eyes of persons who in other respects are very close to you in the direction you are taking. I leave it to your conscience to intoxicate itself with the divine beauty of Autocracy; only continue to have the good sense to contemplate it from a reasonable distance,—when near, it is not so beautiful, and is apt to be dangerous. You placed yourself too high in the opinion of the Russian public for it to be able to believe in the sincerity of such convictions as this. What I have said may then be summed up in the name of "man of genius." Bielineski goes on to accuse him of views of personal enmity, and touches with bitterness on a passage in the "Periplus," in which Gogol had appeared to speak with personal conviction on this subject. He says that he had not the courage to say that he did not share the opinion of their admirers. "These persons," says Bielineski, "may in their admiration of you have made more notes with their applause than the case required; but after all, their enthusiasm sprang from so pure and noble a source that it was only sincere, and it behooves us not only to print new sketches of life, but not even two lines on the subject till I have returned to Russia, have seen it with my own eyes, and touched it with my own hands." Neither Bielineski nor Gogol ever returned. Bielineski died in France of the plague after the appearance of this passage in the "Periplus." The book may be suspected of having its origin partly in political feelings.

Soon after the appearance of the book which raised his fame to its highest point, the author, whose health was bad, obtained a pension and retired to his native city of St. Petersburg. He was honored by a visit from the son of the time of the publication of "Select Passages from N. Gogol's Correspondence with his Friends" ("Vubranovnya Miestia is Perepiiska s Druznami"). His liberal friends found with surprise that the satirist of Russia, when at home, had become the panegyrist of Russia, autocracy and all, who beyond the frontier. Bielineski, who was one of the principal, attacked in so far as the "Sovereigns," one of the leading reviewed in St. Petersburg, in an article which could hardly have been expected to pass the censorship. Gogol addressed to him a letter of remonstrance, protesting that the change which had taken place in his opinions was the result of conviction, and the reflection of the "Sovereigns." In a letter to "Zriiiza," or "Polar Star," a Russian periodical issued in London in 1855. "Yes," says Bielineski, "I loved you with all the passion with which a man warmly attached to his country, can be found, and I love the great leaders in the path of self-consciousness, development, and progress. You had good cause indeed to be shaken out of your repose of soul, for a minute at least, when you lost the right to such love as this. I do not speak thus because I consider any feelings of mine an adequate recompense for such genius as yours, but because in this respect I do not
gives off sulphur when strongly heated, while gold melts without any such odour.

Native gold is to a large extent obtained from alluvial washings. It also is found disseminated through certain rocks, especially quartz and talcose rocks, and is often contained in pyrites, constituting the auriferous pyrites; the deposits of gold-dust has proceeded from some gold-bearing rocks.

Gold is widely distributed over the globe. It occurs in Brazil (where formerly a great part of that was obtained), along the spine of mountains which runs nearly parallel to the coast, especially near Villa Rica, and in the province of Minas Geraes; in New Granada, at Antioquia, Choco, and Guion; in Chili; sparingly in Peru and Mexico; and in the southern of the United States. In Europe it is most abundant in Spain and Portugal, in the province of Castille, in the Carpathian Mountains of Bohemia, in Transylvania, at Kapnik, Vorospatak, and Offanubay; it occurs also in the sands of the Rhine, the Reuse, and the Aar; on the southern slope of the Pennine Alps, from the Simplon and Monte Rosa to the valley of Aosta; in Piedmont; in Spain, formerly worked in Asturias; in the county of Wicklow in Ireland; and in Sweden at Edelfors. In the Ural Mountains there are valuable mines, also in the Caillies Mountains in Little Tibet. There are mines in Africa at Kordofan, Katanga, and Assam, in the Sahara, in the western part of Africa from Senegal to Cape Palmas; also along the coast opposite Madagascar, between 23° and 25° S. lat., supposed to have been the Ophir of the time of Solomon. Other regions in which gold is found are the interior of Abyssinia, Formosa, Ceylon, Java, Sumatra, and the Philippines.

Until lately nearly all the gold of commerce came from Asiatic Russia and Mexico, but recent discoveries of gold in California and Australia have opened new and vast sources of supply.

From 1860 to 1700 the entire supply of gold for Europe was obtained from America, whose mines are estimated in the one hundred years to have produced 337,500,000L worth of the precious metal. During the 14th century the supply of gold and silver was still mainly derived from the Americas, the great mines of Valencianas producing 125,000l. sterling per annum for 40 years, and the district of Zacatecas adding largely to the amount, although there were rapidly failing towards the end of the century. A great increase of gold was produced from the mines of Russia, which is still very productive; they are principally alluvial washings, and these washings seldom yield more than 65 grains of gold for 4000lbs of soil, never more than 130 grains. The alluvium is generally most productive where the loose material is most ferruginous. The mines of Ekaterinburg are in the parent rock—a quartz constituting veins in a half-decomposed granite of Beresit ish, which is connected with talcose and chloritic schists. The shafts are about 500 feet deep, and thence lateral galleries are run to the veins. These mines afforded between the years 1725 and 1841 679 lbs. of gold, or about 30,000 l. troy. The whole output of these mines yields in 1843, 970 lbs. of gold, or 42,000 l. troy, half of which was from Siberia, east of the Urals. In 1843 the yield was nearly 60,000 l. troy; in 1845, 62,000 l. troy; and in 1846, 75,325 l. troy.

In the five following years to 1851 nearly 296,832 lbs. troy weight of gold have been raised in Russia.

At the Transylvania mines the gold is obtained by mining, and these mines have been worked since the time of the Romans. The annual yield of Europe exclusive of Russia is now about 200,000 l. troy. The sands of Danube contain gold in small quantities. The sands of the richest quality contain only about 56 parts of gold in 100,000,000. Sands containing less than half this proportion are worked. Africa yields annually at least 4500 l. troy, and Southern Africa 1250 l. troy. For an account of the gold region and gold-produce of California, see California, S. 2.

From November 1850 to June 1851 the Bank of England issued 9,000,000 sovereigns, being at the rate of 18,000,000 a year. The increase in the circulation of the coin, gold coins, that the rate of production can scarcely keep pace with the demand.

It may be interesting to know, that from the account kept at the Bank when the light coin was called in, in 1842, that 12,000,000l. received light coin, and 36,000,000l. still circulated; in 1840, 100,000l. may be regarded as the quantity of gold coin in circulation, allowing from 3 to 4 per cent. for the natural wear of the coin.

In the year 1856 there were coined at the royal mint 4,806,160 sovereigns, and 2,391,909 half sovereigns; total 7,200,114½ l. 10s.

A large quantity of gold is consumed every year in arts and manufactures, and thus regularly removed from the stock of our circulating wealth. In Birmingham not less than 1000,000., of fine gold are used every week, and the weekly consumption of gold leaf is as follows:

<table>

Total 584 weekly, of which not one-tenth can be recovered. For gilding metals by the electrolyte and the water-gilding processes not less than 10,000 oz. of gold are required annually. One establishment in the Potteries employs 3000l. worth of gold per annum, and nearly 2000l. worth is used by another. The consumption of gold in the Potteries of Staffordshire for gilding ornament has also set in, and the rose-colour varies from 7000 to 10,000 oz. per annum.

The Indies and the Ephruses were the earliest spots whence man obtained the precious metal, gold—Nubia and Ethiopia on the south, and Siberia on the north opened up to the world its treasures as a means to procure and to indulge human luxury. Europe then began to unfold her golden stores, and Illyria and the Pyrenees, together with the land of the Hungarians and many parts of Germany to the Rhine, were sought successfully for gold. On islands yielded something to the store, and then the New World of the Americans opened by Columbus a source from which the Old World was to supply its golden waste. On and on still westward rolled the golden ball, until at length it rested in California and Australia. Rush equally to that new El Dorado, and the man of China is found at the side of the English gold streamer. Then, as if to double the girdle, the islands of the Pacific and our own Australia open their expanse to the precious metal.

Australia is undoubtedly the most important gold-bearing district in relation to Great Britain. Her shores are now being crowded with emigrants from the mother country seeking the precious metal, and in proportion to her population she is now undoubtedly, in this point of view, the richest country of the world. [Australia, S. 2; Emigration, S. 2.]

For the purpose of guiding those who are seeking Australia on account of its gold, the professors of Natural Science, in the Museum of Practical Geology, delivered a course of lectures as follows:

1. 'The Geology of Australia, with Special Reference to the Gold Regions,' by J. Beete Jukes, M.A., F.G.S., Local Director of the Geological Survey of Ireland; author of Sketch of the Phænochemistry of Ores.

2. 'On our knowledge of Australian Rocks as derived from their Original Ores,' by Edward Forbes, F.R.S.

3. 'The Chemical Properties of Gold, and the Mode of Distinguishing it from other substances resembling it,' by Lyon Playfair, C.B., F.R.S.

4. 'The Dressing or Mechanical Preparation of Gold Ores,' by W.W. Smith, M.A., F.G.S.

5. 'The Metallurgical Treatment and Assaying of Gold Ores,' by John Forbes, Rhine, F.R.S.

6. 'The History and Statistics of Gold,' by Robert Hunt, Keeper of Mining Records.

We subjoin an account of the auriferous rocks of Australia from the lecture of Mr. Jukes:

'In Mr. Arrowmith's map appended to the Parliamentary Report just issued, all the auriferous spots are marked in yellow. They occur at intervals along the flanks of the Great Eastern Chain, or on its lateral spurs and subordinate ranges through an extent of country about 100 miles in length, as far as far as from London to Gibraltar or the confines of Turkey, or as from London to Iceland in a straight line. The principal localities marked on this map are Grafton Range and Burnet River, north of the Condamine; Stanly Creek and parties to be regarded as containing several spots in the neighbourhood of Liverpool Plains; the Turon and Conobolas on the Macquarie, below Bathurst; the Abercrombie River at the head of the Lachlan; some spots...
on each side of Breadalbane Plains; the Breadwood and Arlenness diggings in the Shoaheaven district; Lake Eimeo in the Australian Alps; and Ballarat, and Mount Alexander and Erskine's Blackwood, north-west of Port Phillip.

"In every one of those localities granite and metamorphic rocks occur, and quartz veins are frequently spoken of. This is an important fact to bear in mind.

"The discovery of gold was first mentioned in the gold being seen in the actual rock, but in the drift clay, sand, and gravel, or lying loose on the surface of the ground. The Greenwood of gold, indeed, found by Dr. Ker, north of Ballarat, is described as a block of highly auriferous quartz,lying in a series of great rocks, evidently derived from a broad quartz vein running up the hill behind them. Such a mass, indeed, could hardly be transported far from its original site by any conceivable current of water.

"The superficial drift in which the diggings have been carried on is composed of a layer of rich black alluvial soil, and below that grey clay; below that again was a description of red gravel, which was sometimes very good; then red or yellow clay, in which gold was found; and then a stratum, varying in thickness and color, which was described as having no valuable gold, and was called the 'sandy clay.' The next stratum was of hard white pipe-clay, which was a decided barrier. Immediately above it was a thin layer of chocolate-coloured clay, soft and ashy. This was the celebrated blue clay, and was a stratum of great value.

"The ground on which the diggings were situated was a sloping bank. The blue clay is found near the surface on the brow of the hill, that is, at the depth of about a foot; but its sometimes necessary to dig 20 feet before arriving at it.'

"Mr. Latrobe, governor of Victoria, describes the Ballarat diggings as carried on through—

"1. Red ferruginous earth and gravel.
2. Brecked yellowish and red clay.
3. Black sand, associated to by brown and greensand, and void of any ironstone set in very compact clay, hard to work.
4. Blue and white clay.
5. Pipe-clay.

"In some workings the pipe-clay may be reached at the depth of 10 or 12 feet, in others not at 30 and upwards."

"To enter farther into the details of the several diggings would be alike tedious and useless. I must refer you for them to the reports of the season, from the first of December to the 1st of February and the other in June, and to the many small publications with which the shops are now swarming.

"My object to-night has been to give you such a rough sketch of the geology of Australia, and of the geological facts and circumstances of the gold diggings; especially the record of the quantity of gold, as may be of use to those intending to emigrate there.

"In conclusion, I may perhaps be allowed to utter one word of advice.

"Gold-digging is very hard work—just such work as you see navigators at in a railway cutting, or brick-makers in a brick-pit. You must work hard all day, lie hard all night, with little shelter, often with scanty food, and with nothing of what you have probably been accustomed to consider necessary. If you find you have no luck at the diggings, or if your health, or strength, or resolution fail you, do not therefore give up or despise altogether. You go out to dig for gold; do not be ashamed to dig for anything else. I speak to those who have been hitherto unaccustomed to manual labour. Recollect, it is the avowed object of your voyage, and the only thing you have to trust to. If you fail to dig up gold there are lands to be ploughed, sheep to be bred and sheared, cattle to be tended, corn to be sown and reaped—every one of these, for honourable occupations as digging for gold. Go, then, with a bold and resolute heart, determined to get your living by the strength of your own arms and the sweat of your own brows; and be assured that industry and perseverance lead to fortune in Australia with fewer impediments and uncertainties in the way than in any part of the world."

Since the above was written, other districts in Australia have yielded the precious metal, and every day is adding to our knowledge of the wide extension of this metal on the surface of the earth.

GOLD COAST COLONY. The Gold Coast is part of Upper Guinea, but its boundary is not exactly determined. Geographers state that Cape Three Points (20° 30' W. long.) is the northernmost point of the coast; but our navigators extend it farther west to the small river Ashantee, which is about 180 miles from the coast, and nearly 70 miles E. from Cape Lahoo. On the east, the mainland edge of the river Lagos (4° 20' E. long.) is generally considered as constituting its boundary towards Benin, though the mouth of it is an area of uncertain boundary, as shewn on the name of the Slave Coast. In the interior are the powerful kingdoms of the Ashantees and Dahomey, on which most of the small states along the coast are dependent. According to Governor Hill, in his dispatch to the Secretary of State for the Colonies, transmitting the 'Black Book,' the whole of the territory under British protection is estimated to include about 5000 square miles of country, with a population of about 400,000. In a dispatch of April 10th, 1853, however, Governor Hill stated that the estimate of the population to be exaggerated, and that it is probably not more than 300,000. The revenue of the colony is derived from a government grant of 4000l. per annum, a duty of half per cent, ad valorem on all imports, and certain small fees. The income for 1853 amounted to 12,434l., the expenditure to 12,045l. The value of the imports for the year 1853 amounted to 60,000l.; the value of the exports for the same year amounted to 115,000l. The imports for 1854 amounted to 60,000l., and to 110,000l. for the year 1855 to 200,000l. The chief article of export is palm-oil.

Nearly in the centre of the coast is the fortress of Accra. The country west of Accra has an undulating surface, with a small proportion of level ground; the hills are covered with shrubs and trees, and the surface comparatively level; the soil is black and high, is rocky and bold. At Accra the low country begins, and extends a considerable way to the eastward. It is a fertile, open, and level plain, which contain extensive savannahs covered with high grass; but in some parts it is thickly wooded with fine trees. The shores here are flat and sandy. There are no harbours along the coast; and as the surf is very violent, the trading vessels are obliged to anchor four or five miles from the beach. This coast was formerly much frequented by the American and English traders, for slaves. At present it is visited by a few vessels for palm-oil, gold, and ivory; they give in exchange fire-arms, iron, and ironware, tobacco, rum, Manchester cottons, and some other articles.

The whole of this coast being near 6° N. lat., is considered one of the hottest countries on the globe; yet the mean temperature is only 75°, and in the cold season the thermometer sometimes falls to 70° or 74°. During the Hamattan season of December, January, and February, the sky is as dreariest and coolest part of the year, the wind blows from north-east. The great rainy season begins in March, and continues to the beginning of June. From June to the end of September is the warm season, which is the most unhealthy, and the worst time of the year for residence. The winds are then than at other times, and generate fevers. In October and November showers of rain are frequent. Except during the Hamattan season, the winds blow from the west in the middle of the day, from 11 to 3 o'clock, but in the evening from south-west, and in the morning from north-west. The climate is in general unhealthy, especially to Europeans on their arrival. Every person is attacked by a fever, which is called the seasonings. This fever in many instances proved fatal; but it is strictly that of late years has shown a prudent person to get the quinine has been found exceedingly useful in promoting to the recovery of persons attacked by the fever.

Cape Coast Castle is the principal English fortress; it is situated in 5° 30' N. lat., 1° 15' W. long., and covers a considerable area. It is armed with seven guns for officers of the 60-pounders, and barracks for the private soldiers. There are some spacious warehouses. It is built on a rock close to the sea. Near it are the small outports called Fort William and Fort Victoria. The town is both strong and commodious for a place of considerable extent; it has about 10,000 inhabitants, of whom about 20 are Europeans. The streets are regularly arranged, but the houses are of mud, and huddled together. Within Cape Coast Castle is a government-school, which in 1822 was attended by 163 boys.

The other forts are Accra, Annamaboe, and Divoce. Fort St. James at Accra is occupied by a small garrison. The native population is stated to be about 3000. The fort is situated on the coast in 5° 32' N. lat., 1° 18' W. long, and the station is regarded as one of the most healthy on the Gold Coast.
Coast.

Two insurmountable barriers barred its entrance at Accra in 1854. Several unsuccessful attempts were made to suppress the second insurrection. Near Accra is the Dutch fort of Crevecoeur. About 3 miles E. from Accra is the fort of Christiania, and about 30 miles N.E. from Accra is the fort of Fredensborg, both recently purchased from the Danes by the British government. The purchase was made on condition that the British should be allowed to embrace the area of territory under British protection. Annamboe has been noticed separately. The population is said to be about 4500. The exports include the articles usually sent from this coast, namely, palm-oil, gold-dust, ivory, and the implements of British manufacture. The goods of a useful description, besides arms, gunpowder, spirits, and wines. Annamboe is an entrepot of commerce for Ashantees and the interior. Diyarro is situated in 4° 45’ N. lat., 1° 57’ W. long. The British have fitted up a dock for vessels of 100 tons to take in their cargoes. The native population inhabiting the town is about 1200.

The introduction of civilizing influences to the native population of the Gold Coast, is chiefly owing to the labours of the Wesleyan missionaries. From the dispatches of successive governors of the colony, addressed to the Secretary of State, it would appear that considerable progress has been made in communicating to the natives the benefits of an English education, and of an industrial training. In the year 1823 the Wesleyan chapels were attended by upwards of 6000 persons, and about 1200 children were in attendance at the schools of the mission. Mr. Freeman, the missionary superintendent, established in 1851 an industrial school and girls’ school, 10 miles from Great Castle House, near Accra. In February 1852 there were 28 native youths under training at this establishment. On December 31st 1852 Mr. Freeman, writing to Governor Hill, says, “We have now about 750 vines and 3000 coffee plants. We have indeed made great progress, and I trust we may be able to increase these, and to afford the natives means of building and clothing themselves, and in general to promote their well-being efficiently and speedily.” The Wesleyan Missionary Society expends about 5000l. a year on the Gold Coast Mission. Among other evidences of advancing civilization may be noticed the erection by the natives of many neat cottages for the residence of the missionaries, with the most evident pretension to the conveniences and comforts of European dwellings, and the construction of several good roads to facilitate communication between the towns and villages in the interior. The roads have been constructed voluntarily by the natives under the direction of the missionaries. These encouraging features have been more particularly noticeable in the neighbourhood of Abakrampa, the capital, and Domonaa, the second town of the Abrab tribe and district, in the Cape Coast territory. In some of the principal towns of the interior chapels for Christian worship have been built by the chiefs at their own expense.

Governor Hill has endeavoured to enlist the sympathies and co-operation of the native chiefs, by forming them into a kind of college, including a constable, with a missionary executive at its head. Each chief has agreed to pay a tax of £5 yearly for each person belonging to his tribe: from the fund thus provided each chief is to receive a stipend equal to the dignity of his position, and from it is to defray the cost of such general measures of improvement as the legislative body may agree to undertake. Besides the school at Cape Coast Castle, already noticed, the Governor has recently established one in the interior, which in April 1853 had 84 scholars, and he proposes to establish schools at such places within the range of his government as have not been already supplied by the Wesleyan body. He has also employed the natives composing the Gold Coast coast-guard of 253 non-commissioned officers, rank and file, in executing works of public utility, giving them the opportunity of attending the regimental school when they can spare the time from other service. In this way many members of the corps have made considerable progress in reading, writing, and a knowledge of mechanical arts. By their labours 40 miles of a military road has been opened through the Assin country, directly into the interior towards the capital of Ashante; and a fine carriage-road to Annamboe was in process of construction in April 1853. On this road a handsome bridge has been constructed. It enters the town, the granite for which had been first quarried by the soldiers from a deposit opened by them in the immediate neighbourhood.

GOO.

In actions for the non-delivery of goods, the plaintiff, if successful, may now have the same alternative judgment as in the action of Detrussion (S. 3) ; that is, either to have the goods themselves specifically delivered to him, or the value of them assessed by the jury. This most beneficial change in the law is made, and an appropriate writ of execution, viz. the writ of detrussion, and the form of Detrussion, is added by the Martensdale Law Amendment Act 1855, 19 & 20 Vict. c. 97.

GOOLE. [YORKS.]

GOOSE-GRASS. [CALIMUM, S. 1.] A grass, of small stems, of a yellowish-green, with a yellow tinge, and the flowers belonging to the order Polyphylloa, and the type of the family Gorgoneae. It has the following generic characters:—Polyphylloa-mass rooted, arborescent, consisting of a central axis backed with a polypodiferous axis; the axis horny, continuous, and brown; the stipes spiny, the otona, or cymes of the axis, stout, at times, when soft and fleshy, when dried porous and friable; the oriches of the polyphylloa-cells more or less protractant. The species of Gorgonius thus defined are not numerous. Dr. Johnston enumerates four species as being found on the British coast.

G. verrucosa, the Warted Sea-Fan, is somewhat fan-shaped, much and irregularly-branched, the branches cylindrical, flexuous, backed when dry with a white warty substance, obtuse. remarks on this species are made by Prof. E. Forbes and Mr. M'Andrew in the sound of Stye, where they found it attached to stones in 30 fathoms water.

G. plumonarias, irregularly branched, the branches disposed in a dichotomous order and a flatish form, cylindrical in the outer stem, but appearing as simple, terminal, surrounded at top by little spine. This is the Warted Sea-Fan of Ellis, and is found on the Cornish coast, but is rare.

G. anceps, the Sea-Willow of Ellis. It is branched, dichotomous; branches of this species was dredged by Prof. Forbes, and is often found in the sound of Stye, and also in Shetland. Turgeon, from the Ural, seems to be identical.

GRAINING. [LIOCRUSIS.]

GRAMINACEA. [GRAMINACEAS.] The following list of British genera is from Babington's "Manual of British Botany."

Dipteria. Signet.
Avena. Phaloria.
Barbula. Scirpus. Scirpus.
Sputa. Elymus. Lepturus.
Spergula. CCanadianus. Anthracenthrum.

G. frutetum has been found on British coasts, but it has been undoubtedly accidental.

(Johnston, British Zoophyta.)

GOTHITE, A Mineral, to which also the name Lepidolite is given. It is a hydrous peroxide of iron, differing from the brown iron-ore by containing half as much water. The crystals are of a brown colour, and blood-red by transmitted light when sub-transparent. It has a hardness of 3; and its specific gravity 4 to 4 9. It is found basaltic rocks of the same age, but in Cornwall, also in Siberia. Turgeon, from the Ural, seems to be identical.

GRATING. [LIOCRUSIS.]

"The family is very numerous. Pennou's " Synopsis of British plants contains 812 species, 1-26th part of all the plants there enumerates. In the system of Roemer and Sclater, we find, for instance, that perhaps the just proportion will be as 1 to 20 or as 1 to 16. Greater still will be their proportion to vegetation is general when the number of individuals is taken into account, for it
this respect the greater number, may perhaps the whole, of the other classes are inferior. With regard to locality in many cases maize being raised in this form belong Portuguese, Spain, part of France on the Mediterranean coast, and further, the countries of the East, Persia, Northern India, Arabia, Egypt, Nubia, Barbary, and the Canaries Islands; in these latter countries however the culture of maize or rice is perhaps not so extensive as in the European countries. In the temperate zone the old continent, in China and Japan, our northern kinds of grain are very unfrequent, and rice is found to preponderate. The cause of this difference between the east and west is no doubt the vegetation of the manners and peculiarities of the people. In North America, wheat and rye grow as in Europe, but more sparingly. Maize is more reared in the western than in the old continent, and rice predominates in the southern provinces of the United States. In the torrid zone, maize predominates in America, rice in Asia; and both these grains in nearly equal quantity in Africa.

2. The leaves of the tropical grasses are broader, and approach more in form to those of other families of plants. Of this the genus Paspalus affords many examples.

3. Separate sexes are more frequent in the tropical grasses, and in the American species, Paspalum, Glyceria, Ischaemum, Gulippe, and many other genera which only occur in the torrid zone, and are found there in perfection, are monocous or polygamous. Holcus is perhaps the only extra-tropical genus with separate sexes.

4. The extra-tropical grasses on the contrary far surpass the tropical in respect of the number of individuals.

5. That compact grassy turf, which especially in the colder parts of the temperate zones in spring and summer composes the green lawns and pastures, is almost entirelywanting in the torrid zone. The grasses there do not grow crowded together, but like other plants, more dispersed. Even in the northern parts of Europe the assimilation to the warmer temperate zones in leas, is incomparable. "Arundo donax" by its height reminds us of the Bamboo, Suckernum Rubrum, S. Teneriffi, Imperata arundinacea, Leymus croats, Leymus aperati, and the species of Andropogon, Glyceria, etc., by separate sexes exhibit tropical qualities. The grasses are also less greedy, and meadows more occur in the south than in the north of Europe.

The generality are social plants.

The distribution of cultivated grasses is one of the most interesting of all subjects. It is determined not merely by climate, but also by the condition of the soil, the traffic of the people, and often on historical events. Within the northern part of Europe agriculture is found only in a few places. In Siberia grain reaches at the utmost only to 60°, in the European part of Russia to 72°, in the upper parts of the Kamtschatka there is no agriculture even in the most southern parts (51°). The polar limit of agriculture on the north-west coast of America is to be somewhat higher, for in the more southern Russian possessions (57° to 68°) barley and rye come to maturity. Only in Europe, namely in Lapland, does the polar limit reach an unusually high latitude. Beyond this dried fish, and here and there potatoes, supply the place of grain.

The grains which extend farthest to the north in Europe are barley and oats. Those, which in the milder climates are not used for bread, afford to the inhabitants of the northern parts of Norway and Sweden, a part of Siberia and Scotland, their chief vegetable nourishment. Rye is the best, and is most frequently cultivated. In the zone where rye prevails wheat is generally to be found, barley being here chiefly cultivated for the manufacture of beer, and oats supplying food for the horses. To these there follows a second class, best cultivated in Eastern Asia where rice is also raised; in their most widely distributed form bread. The middle and south of France, England, part of Scotland, a part of Germany, Hungary, the Crimea, and Caucasus, as also the lands of middle Asia, where agriculture is followed, belong to this zone. Here the rice is also broad; wine is also cultivated and beer is consumed less raised. Next comes a district where wheat still abounds, but no longer exclusively furnishes bread, rice more, and maize belonging to this zone belong Portuguese, Spain, part of France on the Mediterranean coast, and further, the countries of the East, Persia, Central India, Arabia, Egypt, Nubia, Barbary, and the Canaries Islands; in these latter however the culture of maize or rice is perhaps not so extensive as in the European countries. In the temperate zone of the old continent, in China and Japan, our northern kinds of grain are very infrequent, and rice is found to preponderate. The cause of this difference between the east and west is no doubt the vegetation of the mangers and peculiarities of the people. In North America, wheat and rye grow as in Europe, but more sparingly. Maize is more reared in the western than in the old continent, and rice predominates in the southern provinces of the United States. In the torrid zone, maize predominates in America, rice in Asia; and both these grains in nearly equal quantity in Africa.

The cause of this distribution is, without doubt, historical, for Asia is the country of rice, and America of maize. In some situations, especially in the humid regions of the tropics, wheat is also met with, but always subordinate to these other kinds of grain. Besides rice and maize there are in the torrid zone several kinds of grain as well as other kinds of wheat which the inhabitants use with food, either used along with them or entirely occupying their place. Such are, in the new continent, Yams (Dioscorea alata), the Manihot (Jatropha Manihot), and the Batatas (Convolvulus Batatas), the root of which and the fruit of the Pisang (Pomacea Musa) furnish universal subsistence, the same zone in Africa, Doura (Sorghum), Pisan, Manihot, Yams, and Arachis hypogaea; in the East Indies and on the Indian Islands, Ensete cornace, E. stricta, Ficus carica, and in the South Sea, Sago, Pisang, Yams, Batatas, and the Bread-Fruit (Artocarpus incisa). In the islands of the South Sea, grain of every kind disappears, its place being supplied by the broad-fruits, the pisang, and Taucis rensilida. In the tropical parts of Australia there is no agriculture, its inhabitants living on the produce of the sago, of various palms, and some species of Arrum. In the high lands of South America, there is a distribution similar to the last, and hence it is probable that it was indeed grown to the height of 7929 feet above the level of the sea, but only predominates between 3000 and 6000 feet of elevation. Below 3000 feet it is associated with the pisang and the above mentioned vegetables, while from 3000 to 9200 it is cultivated in Europe and the United States, in the lower regions, yas and barley in the higher, along with which Cheneapodium Queisco as a nutritious plant must also be enumerated. Potatoes alone are cultivated from 9200 to 12,990 feet. To the south of the tropic of Capricorn, wherever agriculture is practised, considerable resemblance with the northern temperate zone may be observed. In the southern parts of Brazil, in Buenos Ayres, in Chili, at the Cape of Good Hope, and in the temperate zone of Australia, wheat predominates; barley, however, and rye make their appearance in the southernmost parts of these countries, and in Van Diemen's Land. In New Zealand the culture of wheat is said to have been tried with success, but the inhabitants avail themselves of the Acrostichum furfuraceum as the main article of sustenance. Hence it appears that in respect of the predominating kinds of grain, the earth may be divided into five grand divisions, or kingdoms—the kingdom of rice, of maize, of wheat, of rye, and lastly of barley and oats. The three first are the most important, and the greatest, but rice may be said to support the greatest number of the human race. Schow, in Jamieson's 'Philosophical Journal.'

The uses of this most important tribe of plants for fodder, food, and clothing are legion. The abundance of wholesome succulents contained in their seeds renders them peculiarly well adapted for the sustenance of man; and if the Cereal Grasses only, such as Wheat, Barley, Rye, Oats, Mais, Rice, and Guinanes corn, are the kinds commonly employed, it is because of the large size of their grain compared with that of other grasses; for none are unwholesome.
in their natural state, with the exception of \textit{Lotus temulentus}, a common weed in many parts of England, the effects of which are undoubtedly injurious, \textit{Bromus pungens} and \textit{catharticus} are said to be emetic and purgative; \textit{Bromus mollis} is also said to be poisonous; and \textit{Festuca quadriglumis} is said to be poisonous. \textit{Muscus nigricans} is injurious to cattle; and some other species are supposed to affect the milk of cows which graze upon them.

Among corn-plants not generally known may be mentioned \textit{Echinochloa crus-galli} on the Coromandel coast, and \textit{Najas Ragaee}, or Mand, elsewhere in India; \textit{Setaria Germamica}, yielding German millet; and \textit{Paniceum frumentaceum}. There are many other species.

The value of grasses as fodder for cattle is hardly less than the value of grain. The best fodder-grasses of Europe are usually dwarf species, or at least such as do not rise above four or five feet from the ground. The most esteemed are \textit{Lolium perenne}, \textit{Phleum}, and \textit{Festuca praetexta}, cultivated, and various species of \textit{Fusco} and \textit{Fusco}. The fountain-grasses of Brazil are of far more gigantic stature, and perfectly tender and delicate. In Australia the favourite is \textit{Antirrhino australis}, or Kangaroo Grass; in India \textit{A. citrata} is also in request; but the most common Indian fodder-grass is Dooba, Doorwa, or Hurryalee (\textit{Cynodon dactylon}). Ganna grass (\textit{Tripsacum dactyloides}) has a great reputation as fodder in Mexico; and attention has lately been directed to the Tusac grass of the Falklands (\textit{Festuca feliciana}), a species forming tusfs five or six feet high, which is said to be unrivalled for its excellence as food for cattle and horses.

The fragrance of our sweet Vernal Grass is by no means confined to it; other species possess the same quality, which is beneficial to the smell of aromatic secateurs, which have in part recommended grasses to the notice of medical practitioners. Sugar is a general product of grass. It exists in great quantities in the Sugar-Cane (\textit{Saccharum officinarum}). Maize so abounds in it, that its cultivation has been proposed in lieu of the sugar-cane.

For economical purposes Grasses are often of much importance. The strong stems of the bamboo are employed instead of timber and cordage. The cuticle of some species contains silky, which occurs in large masses after the burning of a heap of corn, or a stack of hay; in the shape of a colourless glass mass.

(Lindley, \textit{Vegetable Kingdom}; Babington, \textit{Manual of British Botany}).

GREEN IRON-ARTH. [MINERALLOGY, S. 1.]

GREENOUGH, HORATIO, American sculptor, was born in Boston, United States, September 6, 1805. From his earliest childhood he showed a great facility in drawing and modeling, and his tastes were carefully cultivated; but it was not till he was about fifteen that he began seriously to contemplate the adoption of sculpture as a profession. Sculpture had then few practitioners in America, and none of any mark; Greenough took the hint of his Roman uncle to study the art. Rome continued to be his residence for some years, and he has since derived much professional advantage from the friendly services of Thorwaldsen. His health however gave way, but it was speedily restored by a visit to his native land. There however he did not stay long. On his return to Europe he remained long enough in Paris to execute a clever bust of Lafayette, and then proceeded to Florence, where he fitted up a studio, and where during a residence of several years, his principal works were executed. Of that period is his colossal statue of Washington, which now stands in the grounds of the Capitol at Washington; and, the 'Rescue,' or, as it is sometimes termed, the 'Pioneer's Struggle,' now in the Capitol itself: both of these works were executed in the Etruscan style. The work of originality and power, is intended to typify the struggle between the native and European races, and consists of a group of a pioneer rescuing his wife and child from an Indian. Besides these he executed several figures in a purely ornamental style, and in some very pleasing and graceful poetical figures and busts.

He returned to America in 1851 to superintend the erection of his group of the 'Rescue,' and eventually determined not to return to Europe. But his works, done in the Italian climate, and his constitution proved unable to withstand the variations of an American one. After a severe illness he died December 18, 1852.

Greenough will probably not ultimately rank among the foremost of modern sculptors, but he occupies, and will no doubt continue to occupy, a very respectable position; while he will always retain a prominent place in the history of American art as the first of his countrymen who obtained an European reputation as a sculptor. Greenough's attainments were not limited to sculpture: he was an excellent draughtsman; he wrote well both in verse and prose. In private life, while thoroughly unassuming, few men have been more esteemed.

GREENOCKITE. [MINERALLOGY, S. 1.]

GREEN, JOHN EDGAR, architect, claims to be one of those who have contributed by their works to the architectural improvement of the city of Manchester, where great progress in art has been manifested during the last twenty years. Green was born in 1833 in Scotland, and was educated at Dumfries. He received an excellent general education at Edinburgh, and acquired his first professional knowledge from Mr. Walter Newall, architect, at Dumfries. About the year 1856 or 1857 he went to Manchester, where he was for some time an assistant to Mr. Mowat, and to an architect, who may be said to have commenced the improvement which has been referred to. Mr. Atkinson left Manchester in the year 1840, when Green commenced practice on his own account, and who by his energy and exertions raised himself into a prominent position. His works include several churches and schools in the neighbourhoods of Manchester, Bolton, and Preston, and the chapel of the Diocesan Training School at Chester—those being in the medieval style. The church of St. John the Baptist in the Presbyterian churches at Green-Hays and Ancoats, school to the latter, and the Jews' school at Cheetham Hill—all is the style of Northern Italy; several private houses at Manchester, and neighboring towns; warehouses (the class of buildings which, it is said, the architect of Manchester is supposed to have designed) the lodges to the public parks of the same city, and other buildings. His best work however, and it is of great merit, is the bank of Sir Benjamin Heywood, Bart., and Co., of which an illustrated account may be found in the 'Builder' (vol. vii.), where also is a view, or an elevation, of one of his warehouses (vol. viii.). The bank is designed in an adaptation of the Venetian Italian style,—with careful attention to beauty of detail. The new Manchester Institute, completed at Manchester, from his design, has been mainly carried out under Mr. Cornum's superintendence, since the death of the original designer. Grecian died suddenly, after a short illness brought on by over-exertion, on the 26th of April 1855. He was a Fellow of the Institute of British Architects, Honorary Secretary to the Manchester Royal Institution, and took great interest in the local School of Design, the establishment of the Free Library, and other institutions. He possessed a cultivated taste in general art; was a skilful performer on one or two musical instruments.

GREGORY XVI., Mauro Capellari, was born September 18, 1785, at Belluno, in the Lombardo-Venetian kingdom. He entered at an early age into the Camaldolese order of monks. His knowledge of modern languages was so great that he was elected their vicar-general. On the 21st of March 1825, Lea XIII. created him a cardinal, and soon afterwards appointed him prefect of the college De Propaganda Fide. Under Pius
GRO

GROU

venturing at one time, and rendering abortive at another, the repeated attempts of the royalists to open a communication with the English. The battle itself, in a military moment, seeing the republican infantry waver, Grouchy leapt from his horse, placed himself at the head of a few hundred grenadiers, charged the Vendeens, and in spite of a wound he received, pressed them until sunset. In December 1793, on account of his nobleness, he was removed from his command; but his soldiers having heard of his intended departure, flocked to his quarters to prevent it, and Grouchy had to rebuke their attachment, and recall them to obedience. For a short time he was restored to his former command of the Loire, and approached the district in which he was residing, Grouchy mingled in the ranks of the national guards as a private soldier, and assisted in repulsing the enemy. His retirement lasted but eight months. In September 1794, he was restored to the command of the Loire, and on the 11th of June 1796, confirmed him in his post of general of division, to which the soldiers themselves had raised him. Carnot, shortly after, offered him the command of the army of the Côtes de Brest. The republic had, at this juncture, three armies operating against the royalists, and Grouchy feeling that a divided command would injure the service, declined the offer, and recommended that General Hoche should be placed at the head of the three armies. When the battle of St. Cyr took place, Grouchy defeated Charette in his intrenchment at St.-Cyr; and soon after the Vendéan chiefs, Charette and Stafflet, were taken prisoners. At the beginning of 1797 Grouchy was appointed second in command of the army under Hoche, intended to invade England. A detachment of his army dispersed by a tempest, was compelled to regain the coasts of France. Early in 1798 he was ordered to Italy to join Joubert's army, shortly after commanded by Moreau, under the latter, he joined the army of the Rhine, and at the head of a few troops, he took part in the celebrated campaign of Piedmont, where during six weeks 35,000 French soldiers held their ground and manoeuvred in presence of the Austro-Russian army of 80,000 men. Grouchy afterwards distinguished himself at the battles of Piacenza and Castiglione, and on the 7th of July, 1810, he defeated General Bellegarde on the banks of the Bornais. At the battle of Novi, in which Joubert was killed, Grouchy shared with Péronn against the division of the left wing, took 1,800 Austrian prisoners, and charged the enemy eleven times at the head of his dragoons; but being placed between two fires, he fell from his horse, with fourteen wounds, and was taken by the Austrians. The Grand-Duke Constantine sent his own surgeon to attend him, ordered his servants to wait upon him, and never left his side till he died, the accounts published, in eight parts, between 1835 and 1838, 'Rudiments Linguae Umbriæ ex inscriptionibus antiquis odatis; in 1839 'Rudiments Linguae Oscae; 'Die Münzen der griechischen, partischen und indosktyhen Könige von Bactria und K:view of the Termo, Parthia, and Indo-Skythiskian Kings of Bactria and of the Countries on the Indus; and in 1840-42, in five parts, his investigation 'Zur Geographie und Geschichte von Altitalien, a head of his dragoons, and in the bold fidelity of many of his theories. The part he took in the controversy respecting the genuineness of the Sarchinuth's 'History of the Phoenicians,' has been already mentioned. [Sarchinuthia.] Grotefend has also published a history of the Lyceum at Hanover. He died December 16, 1853.

GROUCHY, EMMANUEL, COMTE DE, Marshal and Peer of France, was born in Paris, October 32d, 1766. He entered the artillery branch of the army in 1780. He was already a captain of horse in 1786. The ensuing year, became one of the gardes-du-corps of Louis XVI. However, no sooner did the first dawn of the revolution appear than he quit the gardes-du-corps and ardently espoused the revolutionary principles. In 1789, he was made the colonel of the 2nd regiment of dragoons, a few months later he became major-general, and was appointed to head the cavalry attached to the army of the Alps. In that campaign Savoy was conquered by Montesquieu and annexed to France; Grouchy, perhaps, the only man who contributed to its reduction.

Though scarcely in his 27th year, he began already to be esteemed the first cavalry officer in the French armies. In 1793 he was ordered to join the army of the Côtes de Brest in La Vendée, relieved Nantes, besieged by Charette, and by his skillful manœuvre at the head of the vanguard in the left wing he arrested the progress of the insurrection, pre-
28, 1814, at La Rothière, February 1, and at Vaucamps, February 14. His bravery and skill; at this last battle, rang throughout all France; the anger of Napoleon, which had lasted ten years, gave way before it, and Grouchy was conquered.

After the battle of Ligny, June 16, 1815, Marshal Grouchy was commissioned to pursue the retiring army of Blucher with a force of 34,000 cavalry, and 100 pieces of cannon. In one of his letters, he describes himself as posted at Wavre, and was engaged in action against the Prussian general Thielemann, whilst Napoleon was fighting at Waterloo, on the 18th. The marshal heard the report of artillery, and was strongly urged by his lieutenant-generals to move forward, post himself on the enemy's ground, and declared himself bound to obey the orders he had received from the emperor on the 17th. Fatal as the battle of Waterloo proved to the French army, nothing was publicly said at that period against Grouchy's conduct, nor for three years after. After the second publication of Napoleon, the provisional government appointed the marshal to the united command of all the corps of the grand army; but the entire army amounted to 45,000 men. Banished by France, after the return of Louis XVIII., he withdrew to the United States, where he was living in 1816, when the narrative of the battle of Waterloo, dictated to General Gourgas, at St. Helena, was published. In this account a charge of treachery was made for the first time against the marshal, who was then returned to France. 1816. He was reinstated in all his titles and honours in 1821, by Louis Philippe, and died at Saint-Rémy, May 29, 1847, having been sixty-seven years in the French armies.

GUAJARATE. (Baras Rice, S. 2.)

GUATEMALA. Republic of, Central America, occupies the table-land of Guatemala, with the hilly country between it and the Gulf of Honduras, and a portion of the coast of the same. It lies between 13° 40' and 18° 10' N. lat., 81° 16' and 93° 20' W. long. On the S.B. it is bounded by the Republic of Salvador; E. by Honduras; N.E. by the Gulf of Honduras and the British settlement of Belize; N.W. by the Republic of Mexico; W. by Chiapa, and S. by the Pacific Ocean. The area is about 50,000 square miles; the population about 600,000.

Coast-line Surface, &c.—The general bearing of the Pacific coast from the Salvador boundary to the coast of Honduras is N. by W., and thence to the Rio Sitalapa, the boundary between Guatemala and Chiapa, it is N.W. The shore is for the most part low, the descent from the shore to the level of the sea being gradual, and the beach is from 20 to 30 miles across, being left between its base and the sea; but in many places the shore is high and rocky, and several rocky barriers lie off it. The only port at present frequented on the coast is that of Yelapec, at the mouth of the Rio Michebon, at the S.W. end of the port of escogito, the harbour is better than a halfton, affording no protection for shipping. Ocos, further north, formed by the Barra de Ocos, is also an available port, but, owing to the absence of inhabitants, is not frequented. The low tracts along the coast are very thinly populated. On the northern coast Santo Tomas, in Honduras Bay, is a good and well-sheltered port; and somewhat inland, in the lake known as Golfo Doly, is the port of Yabal, in some respects the principal port of Central America; most of the European goods designed for this coast are from this port, and bring excellent barter for the Produce of the country. This is the chief port of the kingdom of Guatemala, and the most important port of the coast. The trade here is chiefly in textiles, and the Produce of the country is mostly from the province of Yelapec. The table-land of Guatemala occupies all the countries between the isthmus of Chiriquimia and that of Tehuantepec in Mexico; the island in the interior of the peninsulas of Yucatan, usually called the table-land of Yucatan, forms its boundary, most of the European goods designed for this coast are brought by land to Yelapec, and thence transported to the interior by mules; owing to a bar at the mouth of the Rio Doly, Yabal is inaccessible to vessels drawing over 7 feet of water.

the city during the season from February to April; and near
the lake and several hot and mineral springs. The Rice
Michelena, four miles below the town, is a noted

Chimíte, Soil, Productions.—The climate of the table-land
is that of a perpetual spring; the thermometer scarcely
varies throughout the year. The average heat in the
middle of the day is from 70° to 70° F. or 72°; but during
the north winds, which prevail in the days of November
and December, and in May, it sometimes though rarely descends 30 degrees
within a few hours. The rainy season usually sets in in
May and lasts till October; but rain seldom falls except
between 5 and 7 a.m. The temperature of the lake, together
with a light southerly wind, usually starts before daybreak
in June is thunder is frequent; in August and September the Pacific coast is subject to violent storms from
the south-west. The table-land is considered to be very
healthy, but cholera is prevalent, especially among the mixed races, and is accompanied by idiozy. Earthquakes
are painfully frequent.

The soil is generally very fertile. The table-land is
nearly without trees, and even bushes, except on the declivi-
es of the highlands, which traverse it in every direction.
On the lower lands by the Pacific trees of very large size
form extensive forests, and are a source of great natural
wealth; but owing to the thinness of the population and the
want of roads, are at present of little profit. Among the
tribes of the southern part of the province, the yuca, tamarindo,
and manioca, &c. Various medicinal plants are also abundant.
On the low tract by the Gulf of Honduras there is a luxuriant
and vigorous vegetation.

On the table-land wheat and maize of excellent quality
are produced. Coffee is grown, and imported European fruits and vegetables produce well; and tropical fruits and vegetables abound.
In the lower tracts excellent rice is raised. Tobacco, cotton,
sugar, cassava, vanilla, and indigo are raised for exportation.
Most of the cacao, which forms so important an article in the
commerce of Central America, is obtained in Guatemala. The
agricultural resources of Guatemala remain however but
slightly developed. The country is thinly peopled, and
owing to its unsettled state, and the inert character of the
masses, has made little progress in the way of improving the rude systems of cultivation or introducing superior implements; and a considerable portion of the country lies almost waste. Of this unencultivated land a large part
is used as grazing ground, and a rarer large number of
sheep is kept. Sheep are reared in considerable numbers,
the wool, which is somewhat coarse, being used for the
native manufactures. The horses are small, but hardy
and handsome. Mules are numerous, being largely used for
carrying. The coffee produces amounted to 924,468
dollars; the imports to 1,524,420 dollars.

Departments (corregimientos), which, with their chief towns,
are as follows:

1. Guatemala occupies the south-eastern portion of
the territory, has an area of nearly 6,000 square miles, and a
population of about 90,000. The surface of the country is
considerably diversified, the climate equable and genial, and
the soil remarkably fertile. This and the following depart-
ment form the celebrated coffee region (Coffee Operations),
the plant on which the cochineal insect is produced,
grows freely and luxuriantly, especially in the town of
Amatitán, where the chief plantations: the insects come
from the red flowers of the coffee. The coffee continues for about a month. The other productions of this department are
maize and wheat, sugar and coffee, most of which however
is required for home consumption. The principal towns are
Guatemala City, the capital of the state, Amatitán, Escuintla,
and Escuintla (population 40,000). Jazapa, the seat of
the lake of the same name, which formerly depended on the
people who annually resorted to it for bathing, is now,
in consequence of the great increase in the rearing of cochineal,
a rich and thriving place, being a population including the
suburbs of upwards of 6,000.

2. Zaratepeques lies to the west of the corregimiento of
Guatemala; it contains above 1,800 square miles, and a
population of about 60,000, who are chiefly settled in its
western part, in the basin of the Petén. Escuintla is one of the most picturesque in the world, and the soil is
extremely fertile. Maize and other grains, and vegetables
and fruit in great variety, are largely grown. Coffee, cotton,
tobacco, and sugar flourish here, though they are not yet
known to any extent. The chief town is Old Guatemala, but there are
several other populous places around it, notwithstanding
the proximity of the two volcanoes Agua and Fuego, and the frequency and severity of the earthquakes with which it is
visited. The larger of these towns are Chimaltenango,
population 4,000, and Petén.

3. Sololá, the seat of the former corregimientos, contains about 4,000 square miles. The surface is very
much broken, and the soil, especially in the valleys, very
fertile. The climate is colder than in some other parts of the
country. Wheat, maize, and fruits are the chief products.
Sheep are bred in large numbers. Jerez and other coarse
woollens are manufactured. At least three-fourths of the
inhabitants are Indians, who are mostly engaged in agriculture
or weaving; twelve or fourteen of their villages are placed
around the town of Sololá, the seat of the bishopric of the
centre of Sololá. From the midst of this lake rises the
volcano of San Pedro. The chief towns of this department
are Sololá, population 8,000, Atitlan, and Chiquimula, but
neither of them is of any importance.

4. Quetzaltenango, the seat of Quetzaltenango; it
contains above 4,000 square miles, and 70,900 inhabitants;
and is one of the most important of the departments in an
industrial point of view. It has a tolerably level surface, a
temperate climate, and a rich soil. The products are:
maize and wheat, sugar, cacao, and various fruits and vegetable,
which are largely exported to the city of Guatemala,
to Salvador, and Chiapas. Large herds of cattle and mules,
and great flocks of sheep are maintained. The capital
